HARMSWORTH SELF-EDUCATOR

1906

Vol. 1. Pages 1—912

A KEY TO THE HARMSWORTH SELF-EDUCATOR

At the heading of each article in the SELF-EDUCATOR is the number of the group to which the article belongs, and a reference to this key indicates precisely the place of the article in the scheme of the book. This key, therefore, enables the student at any time to understand what has preceded and what is to follow any part of the work to which he may happen to turn.

GROUP 1.

Agriculture. Beekeeping. Gardening.

FARMING. In all its Branches. Dairying. Poultry.
BEEKEEPING. A Practical and Commercial Course.
GARDENING. How to Get the Most out of a Minimum of Land. Gardening for Pleasure and Profit. Market Gardening.

GROUP 2.

Art. Architecture. Glass. Earthenware. Carving.

ART. Theory. History. Painting. Sculpture. Training of an Artist.
ARCHITECTURE. Theory. Styles. Architect's Training.
GLASS AND EARTHENWARE. Including Pottery.
CARVING. Wood. Stone. Ivory. Horn. Tortoiseshell.

GROUP 3.

Biology. Psychology. Sociology. Philosophy. Religion.

BIOLOGY. Including Evolution. Palæontology. Zoology. Anthropology. Ethnology. Heredity.
PSYCHOLOGY. Including Psychical Research.
SOCIOLOGY. Including Political Economy.
PHILOSOPHY AND RELIGION. History and Systems. Christianity.

GROUP 4.

Building. Cabinet Making. Upholstering. Furnishing. Fire.

BUILDING. Excavating. Drainage. Manufacture of Bricks, Limes, and Cements. Bricklaying. Clay Wares. Reinforced Concrete. Masonry. Carpentry. Slates and Tiles. Plumbing. Joinery. Foundry and Smiths' Work. Painting. Paper Hanging and Glazing. Heating, Lighting, and Ventilation. Building Regulations. Building Abroad. In Business as a Builder.
CABINET MAKING, UPHOLSTERING AND FURNISHING.
FIRE. Fireproof Materials. Fire Prevention. Fire Extinction.

GROUP 5.

Chemistry and Applied Chemistry.

CHEMISTRY. Inorganic and Organic. Chemistry of the Stars.
APPLIED CHEMISTRY. Acids and Alkalies. Oils (Fixed Oils and Fats; Waxes; Essential Oils and Perfumes; Paints and Polishes). Candles. Soaps. Glycerine. Glues and Adhesives. Starch. Inks. Tar and Wood Distillation. Cement and Limes. Matches. Celluloid. Manure. Waste Products. Petroleum. Paper Making (including Paper Staining and Uses of Paper). Photography.

GROUP 6.

Civil Service. Army and Navy.

CIVIL SERVICE. Municipal. National. Imperial.
ARMY AND NAVY. How to Enter Them.

GROUP 7.

Clerkship and the Professions.

CLERKSHIP AND ACCOUNTANCY. Complete Training. Bookkeeping.
BANKING. The Whole Practice of Banking.
INSURANCE. Life, Fire, Accident, Marine.
AUCTIONEERING AND VALUING. Practical Training.
ESTATE AGENCY. Departments and Officials of a Great Estate. Training a Land Agent.
MEDICINE. Training of a Doctor. Specialists. Veterinary Surgeons. Chemists and Druggists. Dentistry; The Dental Mechanic. Home and Professional Nursing.
CHURCH. How to Enter the Ministry of all Denominations.
SCHOLASTIC. Teachers, Professorships, Governesses, Coaches, Tutors. Secretaries, etc. Institution Officials. Political Organisations. Lecturers.
LAW. Solicitors and Barristers. Personal and Commercial Law.

GROUP 8.

Drawing and Design.

DRAWING. Freehand. Object. Geometrical. Brush. Memory. Light and Shade.
TECHNICAL DRAWING. For Engineers; Coppersmiths, Tinmen, Boilermakers; Architects; Stonemasons; Carpenters and Joiners; Plumbers.
DESIGN. Book Decoration. Textiles. Wall Papers. Metal Work.

GROUP 9.

Dress.

DRESS. Dressmaking. Underclothing. Children's Clothing. Tailoring. Millinery. Men's Hats. Furs and Furriers. Feathers. Shirts and Collars.

GROUP 10.

Electricity.

ELECTRICITY. Electrical Engineering. Telegraphs and Telephones. Illuminating operations, etc. Cables and Insulated Wire. In Business as an Electrical Engineer.

GROUP 11.

Civil Engineering.

CIVIL ENGINEERING. Surveying. Varieties of Construction. Machines Employed. Roads. Bridges. Tramways. Railways. Water Supply. Sewerage. Rivers. Hydraulics. Pumps. Harbours. Docks. Lighthouses. Foreign Work. In Business as a Civil Engineer.

GROUP 12.

Mechanical Engineering. Military Engineering. Arms & Ammunition.

MECHANICAL ENGINEERING. Applied Mechanics. Workshop Practice. Tools (Hand and Machine). Machine Tools. Portable Machine Tools. Machines and Appliances (A General Guide to Construction). Clocks and Watches. Scientific Instruments.
MILITARY ENGINEERING. Pontoons. Bridges. Fortifications. Rafts. Trenches. Fording Rivers. Conditions in Peace and War.
ARMS AND AMMUNITION. Manufacture of Arms and Explosives.

GROUP 13.

Geography. Astronomy.

GEOGRAPHY. Physical. Political. Human. Commercial.
ASTRONOMY. A Survey of the Solar System.

GROUP 14.

Geology. Mining. Metals and Minerals. Gas.

GEOLOGY. A Course in Geology.
MINING. The Practice of Mining; Coal, Gold, Diamonds, Tin, etc.
METALS. Metallurgy. Iron and Steel. Iron and Steel Manufactures. Metal Work. Cutlery.
MINERALS. Mineralogy. Properties of Minerals.
GAS. Manufacture of Gas.

GROUP 15.

History.

HISTORY. A Short History of the World.

GROUP 16.

Housekeeping and Food Supply.

SERVANTS. Qualifications and Duties of Every Kind of Servant.
COOKERY. A Practical Course.
LAUNDRY WORK. Washing. The Laundry as a Business.
FOODS AND BEVERAGES. Milling. Bread-making. Biscuits and Confectionery. Sugar. Condiments. Fruit. Fisheries. Food Preservation. Catering. Brewing. Wines and Ciders. Mineral Water. Tea. Coffee. Chocolate. Cocoa.

GROUP 17.

Ideas.

IDEAS. The Power of Ideas in Life. Brains in Business.
PATENTS AND INVENTIONS. How to Protect an Idea.
APPLIED EDUCATION. Application of Education in Every

GROUP 18.

Languages.

LATIN. ENGLISH. FRENCH. GERMAN. SPANISH. ITALIAN.

GROUP 19.

Literature. Journalism. Printing. Publishing. Libraries.

LITERATURE. A Survey of the World's Great Books and their Writers. Poetry. Classics. Fiction. Miscellaneous. How to Read and Write.
JOURNALISM. A Guide to Newspaper Work, with Practical Training.
PRINTING. Composing by Hand and Machine. Type Cutting and Founding. Engraving and Blocks. Bookbinding and Publishing.
LIBRARIES. Officials and Management of Libraries.

GROUP 20.

Materials and Structures. Leather. Wood Working.

MATERIALS. The Characteristics and Strength of Materials.
STRUCTURES. The Stability of Structures.
LEATHER. Leather Industry. Leather Belts. Boots and Shoes. Saddlery and Harness. Gloves. Sundry Leather Goods.
WOOD WORKING. Design and Operation of Wood Working Machinery. Wood Turning. Miscellaneous Woodwork.

GROUP 21.

Mathematics.

MATHEMATICS. Arithmetic. Algebra. Plane Trigonometry. Conic Sections.

GROUP 22.

Music. Singing. Amusement.

MUSIC. Musical Theory. Tonic Sol-fa. Tuition in all Instruments. Orchestration. Conducting. Bell Ringing. Manufacture of Musical Instruments.
SINGING. The Voice and Its Treatment.
AMUSEMENT. Drama and Stage. Business side of Amusement. Sports Officials.

GROUP 23.

Natural History. Applied Botany. Bacteriology. Natural Products.

NATURAL HISTORY. Kingdom of Nature. Its Marvels, Mechanism, and Romance. Animal Life. Flowers. Plants. Seeds. Trees, Ferns, Mosses, etc.
APPLIED BOTANY. Tobacco (Tobacco Pipes). Forestry. Rubber and Gutta Percha. Basket and Brush Making. Cane Work. Barks (Cork, Wattle).
BACTERIOLOGY. Pathological and Economic.
NATURAL PRODUCTS. Sources. Values. Cultivation.

GROUP 24.

Physics. Power. Prime Movers.

PHYSICS. A Complete Course in the Science of Matter and Motion.
POWER. A General Survey of Power. Natural Sources. Liquid and Compressed Air.
PRIME MOVERS. Engines. Steam. Gas. Heat. Turbines. Windmills.

GROUP 25.

Physiology. Health. Ill-health.

PHYSIOLOGY. Plan of the Body. Digestive, Circulatory, Respiratory, Locomotor and Nervous Systems. The Senses.
HEALTH. The Five Laws of Health. Personal Hygiene. Environment. State Medicine and the Public Health.
ILL-HEALTH. General Ill-health. Its Special Forms. Common Ailments and Domestic Remedies.

GROUP 26.

Shopkeeping. Business Management. Publicity.

SHOPKEEPING. A Practical Guide to the Keeping of all Kinds of Shops.
BUSINESS MANAGEMENT. The Application of System in Business.
PUBLICITY. Advertising from all Points of View. As a Business.

GROUP 27.

Shorthand and Typewriting.

SHORTHAND. Taught by Pitmans. TYPEWRITING. Working and Management of all Machines.

GROUP 28.

Textiles and Dyeing.

TEXTILES. The Textile Trades from Beginning to End.
DYEING. Dyes and Their Application.

GROUP 29.

Travel and Transit.

TRAVEL. How to See the World. The Business Side of Travel.
TRANSIT. A General Survey of Means of Communication.
VEHICLES. The Construction of Air, Land and Sea Vehicles.
RAILWAYS. The Management and Control of Railways.
SHIPS. Shipbuilding. Shipping. Management of Ships.

THE BIRTH OF BRITISH COMMERCE

CONTENTS OF THIS VOLUME

THE PURPOSE AND PLAN OF THE SELF-EDUCATOR

By THE EDITOR

THE HARMSWORTH SELF-EDUCATOR is designed to be a working school of life. Its purpose is to lay the foundations of an adaptable and successful career for the thousands of young men and women who are bewildered by the increasing difficulty of choosing a definite aim in life, or, having a definite aim, of adapting themselves to its conditions.

It is a difficulty which grows with the growing complexity of life. As science throws open new worlds to conquer, as research reveals new fields of investigation, as education changes old methods for new, the problem of what to do with life becomes more insistent in youth and more perplexing to those in whose hands the moulding of a new generation lies.

Minds, not Machines. It is the purpose of the SELF-EDUCATOR to help to solve the problem which arrests attention and demands solution in nearly all our lives. It is a part of the Idea of Life which produces the EDUCATOR that to live life whole we must understand life whole. Dr. Fitchett has put the truth forcefully and eloquently in his contribution to these pages. It is impossible for any one of us to think of ourselves as separate units, isolated and disconnected members of the human race. Not one stone is separated from another; not one petal of the lily of the field can open to the sun without the working of a thousand laws. And not one of us can do our work well in the world unless every aspect of it has its place in our sympathy and in our education. It is becoming, with every year that goes, harder for those to hold their own whose brain and soul are not behind their work.

The day has passed when a merely mechanical performance of duty achieved success. It is the brain behind the hand, and not the hand alone, which governs the world to-day. The old distinction between manual and mental labour is ceasing to exist. The purely manual worker is becoming a memory of the old days of muddling through. In the days that are coming, the days that are with us, he has no place. The ceaseless rivalry of commerce, the warfare of industry between nation and nation, leaves no room for purely manual labour. Men must be minds, and not machines. The brain in the chemical laboratories of Europe is undermining some of our oldest industries.

The Need for Choice and Training. There will be no room, in fifty years from now, for a SELF-EDUCATOR such as this. With the growth of a rational and national system, the education of the schools will cover the whole of life and not merely touch its fringe. But there is still a pressing need, unfortunately, for the education which tells in the world, the education which can be *applied*. How many boys, how many girls, set out every day on careers for which they are unsuited, or for which, if they be suited, they have not prepared? It is pitiful to reflect on the failure which might have been made success by a little training at the beginning.

The SELF-EDUCATOR has two great aims. It is, first, an earnest attempt to guide young people in the choice of a career and to equip them, or to help them to equip themselves, for the career they choose. It is at once a guide to study and a fountain of learning, a finger-post to industry and a school of practical training.

The Three Classes of Learning. No other single work covers the wide realm which the SELF-EDUCATOR makes its own. It gives, in its thousands of pages, a practical course of instruction in all branches of knowledge. It regards Culture and Commerce as one great whole, insisting on the essential unity of all things. It teaches all forms of knowledge and all their applications in Industry. Knowledge is the root of Business, and Business is Applied Knowledge.

If we divide knowledge into classes, all learning may be brought roughly into three divisions:

COMMERCIAL LEARNING.

The knowledge on which commerce is based—*i.e.* Mathematics, Geography, Grammar, etc.

SCIENTIFIC LEARNING.

Knowledge which may be acquired for its own sake or for humanity—*i.e.* Chemistry, Botany, etc.

PURE LEARNING.

Knowledge acquired for its own sake—*i.e.* Art, Literature, etc.

It is the applications of these branches of learning which make up the world of thought and action, and in the SELF-EDUCATOR we see Education in Action. Education in action, which is Industry, manifests itself in a thousand ways, and the SELF-EDUCATOR is a workshop as well as a school. It is a workshop in which we see going on all the manufactures and industries which make up the commerce of the world.

The Three Classes of Industry. Just as we divided education into three divisions, so Industry, Education in Action, divides itself into three main classes:

EXTRACTIVE.

Industries extracting the materials of nature for utilisation by the manufacturer—*i.e.* Electricity, Agriculture, Fisheries, Mining, etc.

CREATIVE.

Industries creating things out of raw materials—*i.e.* Arts and Crafts, Manufactures, Building, Engineering, etc.

EXECUTIVE.

Industries belonging to the management of affairs; the machinery of the working world—*i.e.* Railways, Ships, Banking, Shops, etc.

The SELF-EDUCATOR comprises all these great classes.

Commerce and Culture. But, though the EDUCATOR—believing that nothing is of any use in this world unless it can be applied—deals at great length with the education which tells in commerce, it is not to be understood that it is a book which merely helps to make money. If it is one of the purposes of the work to be a guide in the choice of a career, to make a successful man of business, efficient worker in any trade or calling, it is not less within its aim to make of him a capable citizen and a scholar. The SELF-EDUCATOR is designed to endow those who study it with a practical knowledge of the world in which we live, an intelligent appreciation of the principles upon which all life and nature are based, and an education which will enable them to be worthy members of society.

It is not an easy task to arrange an ordered plan of knowledge and industry which, while simple and clear, is also adaptable to the exigencies of serial publication. British commerce is a maze in which trades overlap and boundaries cross in bewildering confusion. A court of law once sat nine days, it is said, to decide what was a joiner's work and what was not, and it would require a millennium to devise a scheme of industry in which each task should hold its proper place and each man should perform his proper task. But it is believed that the SELF-EDUCATOR is at least a contribution to such a scheme of unity, and that those who study its methods will find any subject with ease. An exhaustive index, which will form a complete guide to the work, will be issued at the end, but it is desirable that the plan of the work should be thoroughly understood as it appears.

Arrangement of the Work. The work is arranged in twenty-nine groups, most of them divided into sub-sections. It is impossible, owing to difficulties incidental to any work appearing in serial form, to arrange the groups in a perfectly natural relation, and in some cases a merely arbitrary grouping has been unavoidable. But the important consideration in such a work as this—a plan which can be readily understood and followed—has been borne in mind from the beginning, and no elaborate explanation is necessary to explain the plan on which the SELF-EDUCATOR is devised.

The key to its twenty nine groups and their divisions makes it clear at a glance. It is not possible to follow the numerical order of the groups in serial publication, but the adoption of a simple method of sectional headings facilitates the task of the student following a definite course. Most of the headings in the first Part embrace a conspectus of the whole of the group which follows, and in all subsequent parts the headings indicate the group to which the particular article belongs. At the beginning of this Part is a key which shows the plan of the SELF-EDUCATOR at a glance.

Its Scope. No effort has been spared to make the work as exhaustive as such a work can be. A casual glance at any part of it will reveal the thoroughness with which the whole has been designed by the many minds which have concentrated in making it. If we take one subject only from the work, let us say Music, we find that the SELF-EDUCATOR embraces a treatment of the whole theory of music, a course of tuition in every modern instrument, technical instruction in the manufacture of musical instruments, and practical information and advice in the keeping of a music shop. The piano is followed, that is, from the factory to the shop—from the forest and the mine, indeed, to the orchestra and the drawing-room. So, too, with all the innumerable factors which make up the sum of our lives. Look around the room in which you sit, the street in which you walk, the railway platform on which you stand, the office in which you write, and the SELF-EDUCATOR reflects your vision. Into its scope come the beginnings and creation and uses of all the countless things which pass before our eyes wherever we turn.

A Modern Book. The student who wishes to be an artist will find in it a practical course of training; the man or woman who wishes to go through the galleries to see and understand the masterpieces of painting and sculpture will find this work a guide to the interpretation of art. The SELF-EDUCATOR is practical and intellectual too. It is neither a book for making capable craftsmen only nor a book for making scholars only: it is its province to do both, for in the view of life expressed by the SELF-EDUCATOR the two are one. There is no possibility in nature of an ignorant man being a good workman.

It need not be said that the SELF-EDUCATOR is modern on every page. It deals with many subjects on which no text-book exists in any European language. Its coloured plates contain examples of living things so recently discovered that science has not named them. In every department special emphasis is given to those phases of industry and commerce which are likely to develop in the future.

New Ideas. The cry of the politicians, and not of politicians only, is for new industries. It is not the least notable feature of the SELF-EDUCATOR that it points the way to new developments. Its curriculum has no convention. Everything contributing to the fullness of life comes into education as the SELF-EDUCATOR defines it. It contains within it the genesis of new industries and the development of old industries on new lines. A very careful investigation has been made into those phases of industry likely to develop largely in the future, and in this, as in all other ways, it is the effort of the SELF-EDUCATOR to be abreast of a strenuous age. It is a book of modern life, of modern thought, and of modern work, and its realm is as wide as the world

ARTHUR MEE

THE CHOICE OF A CAREER—AND AFTERWARD

By Sir Alfred Harmsworth, Bart.

NOWADAYS, the choosing of a career is not regarded so seriously as it was in the eighteenth, and well towards the end of the nineteenth, century. All who are interested in the welfare of our people will agree with me in describing this as an unfortunate feature of the social life of our time; for the result is becoming painfully evident in the number of young people one observes who are but indifferently equipped for their life-work. While general education has greatly advanced, it has not been so with the systematic study of individual tastes and qualifications in their application to the serious business of life.

The Prime Factor in the Choice. For the professions, it is true, there is to be noted a more thorough system of preliminary training than in the past. One has only to instance the modern doctor to illustrate this. Beyond all question, he or she—for no longer is it a profession of one sex—is better educated than the doctor has been at any period in the history of society. But I am persuaded that we are unable to take so desirable a view of the crafts, and I venture to doubt if sufficient attention is devoted to the training for and choice of a career in any of our great national trades. The practical abolition of the old system of apprenticeship is, in the judgment of many shrewd observers, a misfortune.

Naturally, the prime factor in the choice of any career should be personal taste, inclination. But, unhappily, we have only to look around us to realise how frequently the natural inclination is ignored. The world is full of round pegs in square holes. Who does not know that man who might have been a capable engineer, but is frittering his life away as an inferior clerk, doing work he detests? The engineer who might have been the organiser of a great warehouse; the lady typist who might have been a successful saleswoman, instead of an incompetent correspondent; the governess who would have made a clever typist,—who is not familiar with such as these, round pegs in square holes?

Late Beginnings. Occasionally one finds men who, in later life, have boldly broken away from servitude in occupations they had undertaken in error, or by force of circumstances, and have achieved success in their true vocations. Thus it is that instances of success in middle age and later life are by no means rare. The guiding brain of that great enterprise the Gordon Hotels was until middle age devoted to the law, and so, too, Lord Armstrong, the presiding genius of the famous Elswick Works, who followed the legal profession into manhood, although from his earliest years he had exhibited an extraordinary gift for mechanics. But, of course, there are occasions when it may be wise for a person not to follow the bent of natural inclination and to join loyally in maintaining a business that has perhaps been long identified with his family. Indeed, there is so much room in the world for people of average talent to apply themselves profitably that it might, for instance, be advisable in the case of a young man whose father was a prosperous local practitioner to follow in his father's footsteps. Heredity, undoubtedly, counts for something in the choice of a career, and often goes hand in hand with natural inclination. One thinks of families of successful statesmen, like the Cecils; of lawyers, like the Pollocks; and one remembers the two Pitts in statesmanship, the Stephensons in engineering. In other walks of life there are whole families of mechanics, carpenters, builders, and the like, known to most of us. In this connection, it is worthy of remark that one of the great difficulties which our American cousins have not been able to surmount in their efforts to wrest the cotton-spinning industry from us is the fact that they do not possess generations of trained workpeople such as we have in Lancashire.

England is not Overcrowded. Since there is no rule without its exceptions, one must not dare to dogmatise on this matter of heredity; but it is sufficiently clear that the volume of evidence in its behalf is so formidable that in the choice of a career it is a factor not to be ignored. There are times when it is well deliberately to disregard it—never to ignore it—but more often, by one of those curious traits of character which make the study of human beings so deeply interesting, sons revolt against the occupations of their fathers quite without reason; and too frequently this leads to emigration. Now, in my judgment, emigration is nearly always implied confession of failure. We must, however, make an exception in the case of agricultural workers, for whom there is always a fair field beyond the seas. But the result of considerable personal investigation into colonial conditions in many parts of the empire has persuaded me that the man who succeeds in the colonies might, with equal effort, fare as well at home. I do not believe that the United Kingdom is overcrowded with people. Belgium has no greater facilities for industry than are to be found in our own land, and her population of 7,000,000 people to 11,000 square miles brings Belgium not very far short of being twice as densely inhabited as the United Kingdom; yet it is true that the working classes of Belgium are among the most prosperous in Europe, in some respects being even better conditioned than our own working-classes.

Agriculture. Apart from party politics, which here would be entirely out of place, it may be said with the assurance of general agreement that our country is losing many of its industries, and for their disappearance various politicians have various theories and various remedies. As we are not gaining the newer industries, it follows that we must be marching backwards in some of the old. This is particularly

true of agriculture. And it is towards agriculture that I would direct the minds of those who contemplate emigration for the sake of an outdoor life. There is good reason for the agriculturist emigrating, for, although I have proved farming at home capable of being followed successfully, that is not on the system generally adopted at present. The young man who will make up his mind to learn to farm, and to begin modestly, may be assured of a healthy and not unprofitable occupation.

Agriculture is but one of the vast number of arts and crafts, vocations and avocations, that are dealt with in this all-embracing SELF-EDUCATOR; and I have been tempted to dwell upon it for the reasons I here give, and also because the practical and comprehensive manner in which it is treated in this work is typical of the earnestness with which the whole is being edited by my friend Mr. Arthur Mee, and written by a company of expert writers such as, I venture to submit, has not hitherto been gathered together for any one educational purpose. It is sincerely to be hoped that the reader in search of the best advice on the choice of a career or the best help to self-education will take up the SELF-EDUCATOR in the same earnest spirit as that in which it is being produced. For I fully believe that this work will not only instruct and become a permanent hand-book for daily reference in one's business, but that it will suggest to many readers avenues to usefulness of which they have not previously thought.

Industries of the Future. Nor should it be forgotten that there is always a rise or fall, a changing condition, in the trades of England. I may mention a case with which I am familiar: that of the industries connected with road life. In these industries there are now employed in France about half a million people more than were similarly occupied ten years ago. It is by no means unlikely that at least as large a number will yet be similarly employed in Great Britain, as the populations of the two countries are very nearly the same in extent. Throughout France hotels are being regarnished, fine new buildings are taking the places of old and out-of-date structures, while others are being reared where none before existed. In every town premises are being opened for the storage of road vehicles and depôts for the supply of fuel and other materials required in their propulsion. In a word, a vast new industry has sprung into being, and with its rise numerous other industries are affected, for the most part favourably. The making of self-propelled vehicles is alone a great industry in France to-day, although it is only in its infancy with us. Here, then, is a good example of the changing conditions to which I have referred, upon which the alert young mind should keep a watchful eye. This, one of the newest, as agriculture, the oldest of all occupations, will be found to be adequately treated in this work.

Touching again upon the professions, specialisation would seem to be the trend of the hour. Such ancient callings as the Law and Medicine are showing a marked tendency in this direction. One finds solicitors and barristers, for example, confining themselves chiefly to one of such specialised branches as the law affecting public companies, patents, licensing, divorce or copyright; while most of the leading medical men are known as specialists in the treatment of diseases affecting some particular part or organ of the human body—the chest, the throat, the ear and so forth. Even shopkeeping is developing on specialist lines. The careless general shop, with the pleasant, easy-going, but often unsatisfactory, relations between buyer and seller, is steadily giving way to the great specialist shops, having branches all over the country, each branch in the hands of an expert, the whole controlled by a master expert. I am not to be held as extolling the system as the best of all possible systems. I merely point to its existence and to the fact that it must be regarded watchfully by all seeking vocations.

A General Fault in choosing Trades. Then, again, a general fault in the choice of one's life-work is to follow blindly in the footsteps of some trade which, once profitable, may have ceased to be so; if not in imminent danger of extinction. Within the last two or three years, incredible though it may sound to those familiar with the unhappy conditions of the trade, I have met people learning wood-engraving; an occupation practically—and I regret to think so—dead. They had been articled to some wood-engraver by their parents, who had not taken the trouble to find out that this class of engraving was being superseded, has long been superseded, by the many cheaper and quicker processes of photo-etching.

Thus far, it will be remarked, I have referred mainly to the occupations in which the earning of money is esteemed of prime importance; though that may be allied to genuine pleasure in the work. Of course, there are others. Those who approach music, painting, sculpture, literature, mainly with the idea of accumulating money thereby are not likely to succeed in their ambition. But it may be said of these pursuits, that, followed professionally, they are affording to their professors increasing returns in the material rewards of life; while not less to-day than in times past do they minister to the highest and best that is in mankind. One is often asked, Who buys the modern pictures, and what becomes of the musicians? Well, there are more painters and musicians to-day in England than at any other time, and I do not find, on looking at the official reports of bankruptcies, that the arts are more dangerous than commercial occupations to those who engage in them.

Opportunities for Women. Perhaps the most remarkable feature of latter-day employment is the great increase in the occupations for women. This is a development that may be good, or may be ill; but the tendency is increasing beyond question, and it is the business of the SELF-EDUCATOR to reckon with it. A glance through this work will show

an abundance of occupations for young women, many of which are by no means overcrowded. Speaking personally, as the director of a considerable business, I would like to make complaint of the inefficiency of the majority of young women who attempt to enter business life from shorthand and typewriting schools. We find that not more than 5 per cent. are of any use until they have received a great deal of training in the office; and this would not be the case if they had earnestly endeavoured to qualify themselves for the work during the year or two they had, presumably, devoted to attendance at schools. It is to be feared that many of them take to these pursuits somewhat lightly and without a due estimate of their responsibilities.

Having chosen an occupation in life, one has next to consider a no less difficult question: the means of obtaining success. In some measure good fortune is possible to anyone who is blessed with health. For although all cannot be equally prosperous in their affairs, everyone can make some kind of mark. But not by travelling the old roads.

The Education that makes Money. Education all the world over—I do not say the best education, but the kind of education that makes money—is increasing. As a result, brains work more rapidly, though perhaps not so thoroughly as they did in the past. In every direction we observe that men of active minds are breaking away from tradition and making fortunes by their boldness; in many cases by actual reversal of the policy of their forefathers.

It is not, in my opinion—and I base my statement on knowledge of successful men in many lands—the young man who seeks an appointment in an old-fashioned business, and settles down doggedly to the humdrum, plodding work of doing his duty and observing precedent, who attains, even in the long run, to competency, far less to fortune. There are thousands of men in this and in every land who are hoping to make fortunes that way, and who never will. It is the man who goes into the shop, and, out of his own resourcefulness, his open and nimble mind, shows his employer how to sell new kinds of goods in new kinds of ways, that eventually becomes strong enough to enforce his demands to a share of that shop or some other shop. The new thing and the new way; or the old thing in a new way—either means success if there is concentration behind.

Concentration of Purpose. But this young man must be well in body all the time, so that his mind may be free to devote itself to that prime secret of success—CONCENTRATION. Fortunes come to audacious gamblers now and then, and such rare but disastrous examples do, I know, disturb the minds of young men; for every venture in life has, it must be admitted, at least some slight element of gambling. But, after all, it is *concentration of purpose* that is the backbone of all success in the world, be it that of the poet or the pork packer. He who has cultivated the habit of concentration looks round every proposition so thoroughly that he may be said to have, so far as is humanly possible, eliminated therefrom every element of risk that a man can suppress. The gambler is not only beset by risks, but seeks them; and the fate of the deliberate gambler in business is usually as dismal as that of the gambler in "play."

Finally, after concentration has brought about the initial success, optimism of temperament is necessary. It does much to carry with it those who are around one, associated in a common enterprise, and it brings with it that leadership which is so essential to success in every walk of life. When Ferdinand de Lesseps began to talk of cutting the Suez Canal no one believed him, and, as a matter of fact, he was, as he himself confessed, on the wrong track at first. But gradually his forceful optimism persuaded individual after individual, and then nation after nation, that the thing could and should be done, and it was done, despite the belief of great engineers that the task was impossible. His career is an ideal one to study from the point of view of those who seek success. He may be said to have done an old thing in a new way—for had not the Ptolemies done it 2,000 years before?—and he had concentrated his whole existence on it.

Optimism and Success. Let my last word strike this note of optimism, enthusiasm, once more. Of nothing am I more firmly persuaded than that our own temperament is sure to help or hinder us in the struggle for success. To be nervously apprehensive of failure is literally to invite failure; but to be confident of success, or at any rate reasonably hopeful and determined not to contemplate the reverse, is already to have won half the battle.

ALFRED C. HARMSWORTH

true of agriculture. And it is towards agriculture *that I would direct the minds of those who contemplate emigration for the sake of an outdoor life. There is good reason for the agriculturist emigrating, for, although I have proved farming at home capable of being followed successfully, that is not on the system generally adopted at present.* The young man who will make up his mind to learn to farm, and to begin modestly, may be assured of a healthy and not unprofitable occupation.

Agriculture is but one of the vast number of arts and crafts, vocations and avocations, that are dealt with in this all-embracing SELF-EDUCATOR; and I have been tempted to dwell upon it for the reasons I here give, and also because the practical and comprehensive manner in which it is treated in this work is typical of the earnestness with which the whole is being edited by my friend Mr. Arthur Mee, and written by a company of expert writers such as, I venture to submit, has not hitherto been gathered together for any one educational purpose. It is sincerely to be hoped that the reader in search of the best advice on the choice of a career or the best help to self-education will take up the SELF-EDUCATOR in the same earnest spirit as that in which it is being produced. For I fully believe that this work will not only instruct and become a permanent hand-book for daily reference in one's business, but that it will suggest to many readers avenues to usefulness of which they have not previously thought.

Industries of the Future. Nor should it be forgotten that there is always a rise or fall, a changing condition, in the trades of England. I may mention a case with which I am familiar: that of the industries connected with road life. In these industries there are now employed in France about half a million people more than were similarly occupied ten years ago. It is by no means unlikely that at least as large a number will yet be similarly employed in Great Britain, as the populations of the two countries are very nearly the same in extent. Throughout France hotels are being regarnished, fine new buildings are taking the places of old and out-of-date structures, while others are being reared where none before existed. In every town premises are being opened for the storage of road vehicles and depôts for the supply of fuel and other materials required in their propulsion. In a word, a vast new industry has sprung into being, and with its rise numerous other industries are affected, for the most part favourably. The making of self-propelled vehicles is alone a great industry in France to-day, although it is only in its infancy with us. Here, then, is a good example of the changing conditions to which I have referred, upon which the alert young mind should keep a watchful eye. This, one of the newest, as agriculture, the oldest of all occupations, will be found to be adequately treated in this work.

Touching again upon the professions, specialisation would seem to be the trend of the hour. Such ancient callings as the Law and Medicine are showing a marked tendency in this direction. One finds solicitors and barristers, for example, confining themselves chiefly to one of such specialised branches as the law affecting public companies, patents, licensing, divorce or copyright; while most of the leading medical men are known as specialists in the treatment of diseases affecting some particular part or organ of the human body—the chest, the throat, the ear and so forth. Even shopkeeping is developing on specialist lines. The careless general shop, with the pleasant, easy-going, but often unsatisfactory, relations between buyer and seller, is steadily giving way to the great specialist shops, having branches all over the country, each branch in the hands of an expert, the whole controlled by a master expert. I am not to be held as extolling the system as the best of all possible systems. I merely point to its existence and to the fact that it must be regarded watchfully by all seeking vocations.

A General Fault in choosing Trades. Then, again, a general fault in the choice of one's life-work is to follow blindly in the footsteps of some trade which, once profitable, may have ceased to be so; if not in imminent danger of extinction. Within the last two or three years, incredible though it may sound to those familiar with the unhappy conditions of the trade, I have met people learning wood-engraving; an occupation practically—and I regret to think so—dead. They had been articled to some wood-engraver by their parents, who had not taken the trouble to find out that this class of engraving was being superseded, has long been superseded, by the many cheaper and quicker processes of photo-etching.

Thus far, it will be remarked, I have referred mainly to the occupations in which the earning of money is esteemed of prime importance; though that may be allied to genuine pleasure in the work. Of course, there are others. Those who approach music, painting, sculpture, literature, mainly with the idea of accumulating money thereby are not likely to succeed in their ambition. But it may be said of these pursuits, that, followed professionally, they are affording to their professors increasing returns in the material rewards of life; while not less to-day than in times past do they minister to the highest and best that is in mankind. One is often asked, Who buys the modern pictures, and what becomes of the musicians? Well, there are more painters and musicians to-day in England than at any other time, and I do not find, on looking at the official reports of bankruptcies, that the arts are more dangerous than commercial occupations to those who engage in them.

Opportunities for Women. Perhaps the most remarkable feature of latter-day employment is the great increase in the occupations for women. This is a development that may be good, or may be ill; but the tendency is increasing beyond question, and it is the business of the SELF-EDUCATOR to reckon with it. A glance through this work will show

an abundance of occupations for young women, many of which are by no means overcrowded. Speaking personally, as the director of a considerable business, I would like to make complaint of the inefficiency of the majority of young women who attempt to enter business life from shorthand and typewriting schools. We find that not more than 5 per cent. are of any use until they have received a great deal of training in the office; and this would not be the case if they had earnestly endeavoured to qualify themselves for the work during the year or two they had, presumably, devoted to attendance at schools. It is to be feared that many of them take to these pursuits somewhat lightly and without a due estimate of their responsibilities.

Having chosen an occupation in life, one has next to consider a no less difficult question: the means of obtaining success. In some measure good fortune is possible to anyone who is blessed with health. For although all cannot be equally prosperous in their affairs, everyone can make some kind of mark. But not by travelling the old roads.

The Education that makes Money. Education all the world over—I do not say the best education, but the kind of education that makes money—is increasing. As a result, brains work more rapidly, though perhaps not so thoroughly as they did in the past. In every direction we observe that men of active minds are breaking away from tradition and making fortunes by their boldness; in many cases by actual reversal of the policy of their forefathers.

It is not, in my opinion—and I base my statement on knowledge of successful men in many lands—the young man who seeks an appointment in an old-fashioned business, and settles down doggedly to the humdrum, plodding work of doing his duty and observing precedent, who attains, even in the long run, to competency, far less to fortune. There are thousands of men in this and in every land who are hoping to make fortunes that way, and who never will. It is the man who goes into the shop, and, out of his own resourcefulness, his open and nimble mind, shows his employer how to sell new kinds of goods in new kinds of ways, that eventually becomes strong enough to enforce his demands to a share of that shop or some other shop. The new thing and the new way; or the old thing in a new way—either means success if there is concentration behind.

Concentration of Purpose. But this young man must be well in body all the time, so that his mind may be free to devote itself to that prime secret of success —CONCENTRATION. Fortunes come to audacious gamblers now and then, and such rare but disastrous examples do, I know, disturb the minds of young men; for every venture in life has, it must be admitted, at least some slight element of gambling. But, after all, it is *concentration of purpose* that is the backbone of all success in the world, be it that of the poet or the pork packer. He who has cultivated the habit of concentration looks round every proposition so thoroughly that he may be said to have, so far as is humanly possible, eliminated therefrom every element of risk that a man can suppress. The gambler is not only beset by risks, but seeks them; and the fate of the deliberate gambler in business is usually as dismal as that of the gambler in "play."

Finally, after concentration has brought about the initial success, optimism of temperament is necessary. It does much to carry with it those who are around one, associated in a common enterprise, and it brings with it that leadership which is so essential to success in every walk of life. When Ferdinand de Lesseps began to talk of cutting the Suez Canal no one believed him, and, as a matter of fact, he was, as he himself confessed, on the wrong track at first. But gradually his forceful optimism persuaded individual after individual, and then nation after nation, that the thing could and should be done, and it was done, despite the belief of great engineers that the task was impossible. His career is an ideal one to study from the point of view of those who seek success. He may be said to have done an old thing in a new way—for had not the Ptolemies done it 2,000 years before?—and he had concentrated his whole existence on it.

Optimism and Success. Let my last word strike this note of optimism, enthusiasm, once more Of nothing am I more firmly persuaded than that our own temperament is sure to help or hinder us in the struggle for success. To be nervously apprehensive of failure is literally to invite failure; but to be confident of success, or at any rate reasonably hopeful and determined not to contemplate the reverse, is already to have won half the battle.

ALFRED C. HARMSWORTH

THE UNITY OF THINGS

THE CENTRAL WONDER OF THE UNIVERSE

By Dr. W. H. Fitchett, Author of "How England Saved Europe"

THAT the world—the visible system of things about us—is a kingdom of mystery, an enchanted realm, we know; and it is striking to observe how steadily, as the area of knowledge widens, the sense of the mystery in the very structure of the universe deepens. It is always true, of course, that the wider the illuminated disc, the greater is the curve of encompassing darkness. But this is not all. The wonder deepens in the illuminated area itself. The light does not scatter the mystery; it makes it only the more profound.

And it is curious to note how what may be called the centre of mystery is shifting. It lies to-day rather in the inconceivably little than in the immeasurably great. Science is teaching us that the infinitesimal is almost more wonderful than the infinite. Yesterday the material vastness of the universe burdened the imagination, and threatened to kill faith. The frontiers of the physical universe were being pushed ever back. The heavens grew higher, the depths more profound. New hosts of stars were sweeping continually into view. What a difference betwixt the night-sky that our simple-minded fathers, with unassisted eyes, beheld, and the same sky seen, through, say, the gigantic equatorial telescope of the Lick Observatory! And the wonders seen even by the astronomer's eye through the great telescope are less, by almost measureless degrees, than the wonders registered by a sensitised plate attached to the eyepiece of the telescope.

The Infinitely Little. But to-day, we repeat, the centre of wonder in the physical universe has shifted. The startled imagination lingers not so much over the infinitely great, as over the infinitely little. What a flame of mystic and almost unquenchable fire burns, for example, as we now know, in a microscopic speck of radium! The flame of Arcturus seems, if not commonplace, yet intelligible, when put beside it. It is not some vast aggregate of matter—a planet hung in the depths of space—which seems to us most wonderful. It is the molecule! Beneath the "open sesame" whispered by science, that which was till yesterday supposed to be the ultimate form of matter—the atom—becomes transparent. Its boundaries are passed—and what strange kingdoms stand revealed to knowledge! Here is a system of electrons—inconceivably minute points of electric energy—moving in orbits like the stars, and with the speed of light. The constellations that burn in the midnight skies—Alcyone, and its sister planets—are less wonderful than the starry constellations, packed within the curve of every atom. A system of rushing stars hidden in a molecule! Here is food for wonder of which our fathers never dreamed.

Yet, to the brooding and instructed imagination, the centre of wonder in the system of things shifts once more. Not things, but the relation of things, is that which, when even faintly realised, startles the mind most. Only slowly, in broken gleams of light easily lost, do we come to see that all forces, things, lives, are linked together by subtle and far-reaching ties, so that the whole system, of which we form part, is a unit. The universe is not a cluster of unrelated facts, but an organism. Not a chaos, but an ordered kingdom.

The Identity of Matter. Sometimes we catch, or think we catch, a glimpse of the solidarity of the universe when we are reminded of the identity of widely separated forms of matter; or of the unity which lies behind a thousand varying kinds of force. Let a tiny point of hydrogen flame from a smoker's match be taken, and a gleam of radiance from, say, the belt of Saturn: what can express the interval, measured in terms of space, which separates these two tiny points of fire! Yet, when tested by the spectroscope, they are found to be identical. Here is the revelation of a strange identity of structure, which holds good across the utmost bounds of the universe. And there are hints of identities equally wonderful in every realm.

All forms of force, for example, as science analyses them, run back into one force. What is the pull of gravitation, the leap of electricity, the swift-running vibration of the light, but disguises—or expressions—of that mysterious ether which, according to our latest science, promises to explain everything, but about which we know nothing.

The Time-relation of Things. Yet it is not the identity in structure of things parted by the utmost vastness of space, or the unity—hidden beneath all diversities of working—which links together all the forms of force, that most impresses the imagination. It is, we repeat, the subtle, infinitely close, yet infinitely complex, relations betwixt things which makes the wonder of the universe. Each fact stands related to every other fact; to all that was, or is, or is to be. What may be called, for example, the time-relation of things is, when realised, nothing less than amazing. The child in a board school sees his teacher stand beside the blackboard with a bit of chalk in his hand. What is that bit of chalk to the child, or even to the teacher himself? Merely a convenient substance for making white lines on a blackboard. But, as a matter of fact, that bit of chalk is an ancient cemetery, in which lie buried creatures that lived, and played their part in the system of things, whole milleniums ago! In the yet warm seas of the slowly-cooling planet

floated myriads of infusoria, with power to secrete from the sea in which they floated a sheltering film of lime. As these tiny myriads died, the microscopic facing of lime they wore—or their limy skeletons—sank through the warm unmoving waters to the sea bottom. In process of ages this grew to a white slime; some convulsion of the earth's structure lifted up the ancient sea bed, and the soft white slime became a chalk cliff. And the bit of chalk in the teacher's fingers represents the whole process! What ages, what revolutions, what a measureless geology that little bit of white earth hides in its atoms. It is, in a sense, a perished eternity which the teacher holds in his fingers.

Perished Eternities. The bit of coal, again, that lies in the grate represents, like the bit of chalk, a life that existed, and energies that were in operation, at a period which lies uncounted ages distant. The gas in the burner, the fire in the grate, are but heat of summers that glowed, the flame of suns that shone in an antiquity so far behind us that the imagination cannot even guess its date. Each form of matter that the eyes see or the fingers touch to-day is, in this way, the index of a perished eternity.

All this may, perhaps, seem fanciful. It may stir the imagination, but has no practical significance. What is of supreme significance is the present relation of things to each other; the close, subtle, uncomprehended wedlock which links all forces, all forms of life, into strangest unity. Behind each apparently isolated fact are relations which make it a part of every other fact. Here, again, the illustrations lie close at hand, hidden in familiar things.

A bud on a tree in springtime—a little cluster of swelling leaves, packed in its tight sheath—is the most commonplace of objects. But what brings it there? What bids the close-packed leaves swell? The mysterious forces of spring, it will be answered; the energies of the brown earth, the kiss of the falling rain, the heat of the quickening sun. These are behind the bud, and explain it. But this "explanation" is superficial, and itself needs to be explained. The spring bud, a wiser answer declares, is the index of stellar changes; its explanation runs up into the movements of the planets. That tiny, close-packed bundle of swelling leaves tells that the earth has swung into a new angle to the sun. And if it is asked why the earth has turned one of its aspects thus towards the sun—how far back the explanation must go! The spring bud is only the last link in a chain of movements which runs back not merely to the roof of the heavens, but to the dawn of all worlds. Here is a planetary movement translated into vegetable terms, and set before our senses. We see only the bud; and, if called upon to explain it, think only of that abstraction, "the spring." But the wheeling planets, and the far-off forces that move the planets, are in the tiny curve of that solitary and tender bud.

The Colour of the Rose. What explains the colour that burns on the leaf of a flower—the white in the curve of a lily, the purple in the tiny cup of a violet? The answer, of course, is that the colour comes from the sun. But let all that is included in that answer be realised. The sun is 93,000,000 miles distant; the colour which delights us in the flower—the crimson in the heart of the rose, the scarlet of the poppy—eight minutes ago was actually in the sun, all those immeasurable leagues distant! How did it reach the flower and become visible there? The running waves of light from that far-off sun smites the leaf of the flower. By some process of vital chemistry, which baffles our wisest science to guess, the leaf disintegrates the ray. It selects and absorbs some of the colour elements, and reflects others. The miracle goes on while we gaze, and under our very eyes; it is a living and continual process. What we see is only the last link in a chain of wonders. Nay, it is not the last link; for "every end," to quote Emerson, "is a beginning. Every ultimate fact is only the first of a new series." The disintegrated light on the leaf of a flower sends its vibration through the optic nerve of the eye that looks upon it to the brain behind the eye; and then, by another mystery before which science is dumb, to the soul behind the brain it brings the sensation of colour. The blue in the forget-me-not, the crimson in the rose, the white in the lily are but links in a chain of relations betwixt our consciousness and the sun 93,000,000 miles distant. The tiny flower, it may be said, interprets the ultimate elements of light to our consciousness.

The Pebble on the Beach. A pebble, to take another homely illustration, lies on the beach, and nothing could well be more inert and commonplace. But how came it there? Why does it lie on that exact spot and no other? This, it will be at once said, was determined by the force and direction of the wave that flung it there. But what was behind that wave, and determined its direction and energy? The pressure of the wind; and this, in turn, had for its cause some unknown changes of heat or cold, stretching over unknown kingdoms of space, and determined by forces which run up to the crown of the heavens and back to the beginning of the worlds. In a sense, it would have required a totally different history of the physical universe to have cast that pebble a few inches higher!

It is possible to look at a luminous arc of electric light and see in it only a curve of calcined vegetable fibre, through which an electric battery is forcing a current. The resistance to the current explains the light. But what is there behind the battery; and whence comes that strange force that pours into the arc? Made visible in that flame, again, is a force running to the uttermost bounds of space, and which itself may be but a disguise of that ether which is the ultimate stuff of which the universe is made.

The Inter-relation of Facts. Each familiar fact within the sweep of our sense, in brief, is the index of a whole mysterious history; a process that stretches back to the

first syllable of unrecorded time. Things are symbols; they are but counters in nature's mighty currency. Each movement, each pulse of energy, each form of matter, is but the last link in a chain which runs back into mystery and into eternity.

But there is a deeper wonder than even that which lies in what we have called the time-relation of things—the history that lies behind things: it is the mystic, uncomprehended, yet quick and vital inter-relations of things at the present moment, which, when realised, makes the wonder of the universe. No fact is isolated. No event is solitary. No force works alone. No life exists but as part of all other lives. The nerve system of the human body, which links all its organs into consciousness, is only a symbol of the close-knitted relationship which binds the whole visible system of things into unity. An astronomer watching the disc of the sun sees a pulse of more vivid light sweep across part of its surface. It is an electric storm, kindling the flame of the sun over a certain area to a new intensity. And in every observatory on earth, at the same moment of time, the electrical *instruments record what is happening! These vibrate in rhythm to that pulse of energy in the far-off sun.*

The Opening Flower. *And across all the depths of the space, the greatest things in* the universe call to the smallest; the bud, as we have seen, to the planet; the flame of colour in the flower to the flame of light in the sun. The bud swells as the planet wheels, and because the planet wheels.

What is the relation betwixt a grain of wind-driven sand in a city street and the earth, or the whole system to which the earth belongs? Does not that grain of matter attract every other grain in terms of known law? If destroyed, its withdrawal, it is mathematically certain, would affect the gravity of the earth; it would change its course and speed through space. The planet, it may be said, needs the atom, and would itself be different if the atom were destroyed. So profoundly do even what we call insensate things affect each other; so closely and vitally do they belong to each other! The old doctrine of the conservation of energy is insufficient. The new teaching of science is the identity of all forms of energy.

The Energies of the World. In one pregnant and striking passage, Emerson says "the entire system of things is represented in every particle. There is somewhat that resembles the ebb and flow of the sea, day and night, man and woman, in a single needle of a pine." But this is inadequate. The needle of the pine not merely belongs to the system of things; all its energies pulsate within it. The rhythm of forces in the sea tides, the procession of day and night, is felt in, and shared by, every fibre of the tiny pine needle.

Tennyson was not a scientist, but he had a poet's vision into the meaning of science, and a poet's sympathy with its interpretation of the universe, and he has compressed a true scientific philosophy into half a dozen familiar lines:

"Flower in the crannied wall,
I pluck you out of the crannies,
I hold you here, root and all, in my hand,
Little flower—but *if* I could understand
What you are, root and all, and all in all,
I should know what God and man is."

Solidarity of the Race. Only an accidental flower; planted by no gardener's care, but sprung from some wind-blown seed; yet think what mystic relations radiate from that tiny, unnoticed blossom! Relations with the winds which bore it to the crevice in which it lies; to the rains that watered it, the brown earth that fed it, and the far-off sun from whose untwisted light it takes its colour. And what is true of the flower in the crannied wall is true of every other form of life, or pulse of energy, or shape of matter found in the whole web of things. The universe is a vital unit, and all its parts belong to each other, affect each other, are part of each other.

But if all this is true of the great network of forces, and changes and things, which make up *the visible universe, it must certainly be true—and true in an even higher and closer sense—of the human race, which is the crown of things; the race which has for the material universe the function that the thinking brain has for the* human body. The solidarity of the race—the fashion in which we belong to each other, affect each other, are responsible for each other—is but faintly expressed by the kinship which subsists betwixt material things. *In* the profoundest sense, the race is a living organism. We realise this only faintly as yet. The "solidarity of the race" is looked upon as a figure of speech, a poet's fancy. But the consciousness of that solidarity is growing. It will yet capture the reason of mankind and become imperative to its conscience. And when it has done this it will re-shape society and mould all our politics to a new pattern.

The Living Organism of Society. Our politics to-day are, in many respects, a denial of the great assertion of scripture that "God has made of one blood all nations to dwell on the face of the earth." Our social laws are in too many points in conflict with the very conception of human brotherhood. Hence the disorder in the social system, the strife in the relation of nations. But science in its own terms, and by its own logic, is repeating the teaching of the Bible. It is slowly making visible the solidarity of the physical universe; and the unity of the race is but the highest expression of that solidarity. Vainly do seas divide nations, and diversities of speech or differences of colour—most fatal of all separating forces!—part one tiny fragment of the human race from another. The race, the Bible teaches, and science affirms, is a unit. And, under the laws that govern life, every part belongs to every other part; gains by its health, droops with its sickness, is made glad by its happiness, suffers with its pain.

The whole political history of the race may be described as a parable setting forth in concrete forms the wreck and misery caused by the forgetfulness of its own unity by the human race. One nation has dreamed it could grow great by the destruction of other nations. A class has imagined it could prosper at the cost of other classes. And history, with its record of wars and revolutions, of empires destroyed, and kingdoms wrecked and classes cast down, shows how nature—or rather that Moral Government which is above the universe and uses nature as its tool—has whipped all such selfishness.

Indian Wheat and Kent Marriages. All this is true to-day; it applies to the society of which we are a part. Some examples of the vital relations which link men together lie on the very surface. A heavy wheat crop in India or Siberia means a higher marriage rate in Kent or Staffordshire. The failure of the cotton crop in Carolina means that the looms in Bradford and Leeds are idle. A "corner" in the Chicago Stock Exchange is translated into empty pockets, pawned furniture, and hungry little children in Lancashire. The suspicions and alarms betwixt the nations of the world yield another illustration—in sepia, so to speak—of the fashion in which we belong to each other. If one great Power invents a new rifle and spends millions in arming its soldiers with it, every other great Power must strain its wits to invent a still better rifle, and must tax its subjects to the very quick to pay for the luxury. For every rivet driven into the sides of a German or French battleship, English hammers must drive two rivets into the sides of British battleships. The nations cannot separate themselves from each other, any more than a man, by taking hold of his feet, can lift himself off the earth. The effort to isolate does not really break any bonds. It only inflames all bonds.

The Linking of all Lives. And it is not merely that nation touches nation. Individual is linked to individual; the poet to the clown, the millionaire to the pauper, the sons and daughters of nobles to the ragged child in the slums. We cannot separate our fortunes, or arrest the influences by which we touch each other. Society is a ship in which we are all passengers. What imperils the ship, poisons its atmosphere, relaxes its discipline, casts a shadow of danger on every life the ship carries. Blake, in one tremendous couplet, writes a profound truth:

> "A starved dog at the city's gate
> Foretells the ruin of the state."

The swift instinctive vision of the poet read that deep but as yet unrecognised law that want unfed is the business not only of the poor wretch who feels it, but of the whole society in which the hungry man stands. It points to some social disorder; some false relation betwixt men; some breach of wise and Divine law. The strength of a nation, its wealth, its happiness, are but the sum total of the strength and wealth and happiness of the units which compose it. So a brain left untaught, a conscience unquickened, a faculty undeveloped, a want unfed, represents a loss which makes the state, and every member of the state, poorer.

Unity of the Moral Realm. But this law runs far beyond the boundaries of commerce or of politics. In the moral realm no one will deny the relations which knit men together, and the forces by which they act on each other. In that high kingdom we are bound to each other by ties more subtle than anything matter knows, and surer because of their very intangibility. The shadow of a leaf lying on the glittering blade of a razor will permanently mark it. What can be lighter than a shadow, what harder than polished steel? But the touch of even a shadow marks the steel. And character in each of us is a force that, for good or evil, is perpetually touching all other characters. In the great realm of moral forces, certainly, "no man lives to himself." A fearless, upright soul reinforces goodness in every soul it touches. An evil man radiates wickedness. He taints the general conscience. He makes goodness harder, and evil easier, for everyone about him.

These, of course, are platitudes; but they do not exhaust—they do not even adequately describe—the area of our relations. The profound teaching of Christ, which is yet to transfigure the world and recreate society, is that who touches for good or ill his brother touches Him! Our acts towards each other reverberate to the very throne and person of God. Service to each other is service to God. Neglect of each other is neglect of God. The denial of another's need is a refusal that runs up to the crown of the universe, and sends its echoes forward to the Judgment Seat itself. As Whittier sings:

> "Who hates, hates Thee, who loves becomes
> Therein to Thee allied.
> All sweet accords of hearts and homes
> In Thee are multiplied."

Thinking Universally. We are exhorted by many voices to-day to "think imperially"; and no one will deny the loftiness and wisdom of that appeal. Thought, for us, if we would not fail, must be as wide as facts. We must recognise all ties, accept all duties, feel all the relationships which run out from us, and use all the resources which belong to us. We must "think imperially" in science, or we misread the universe; in politics, or we shall wreck the empire; in commerce, or we shall drift into bankruptcy; in morals, or we shall leave half our duties forgotten and see half our life spoiled.

But though the phrase, "Think imperially," is large, it is scarcely large enough. We must think, so to speak, in cosmic terms! We must consent to feel ourselves part of the whole system of things, touching all lives and all forces, and touched by all. We must think of the universe, not in fragments, but—as its Maker planned it, and Himself thinks of it—as a unit, an ordered kingdom knitted together through all its forms and to its utmost boundaries by relationships so close that they cannot be escaped; yet so subtle that they can hardly be realised.

THE RELATION BETWEEN THE EARTH AND HUMAN LIFE

By Dr Herbertson

Of the many definitions of Geography, which in itself means only a description of the earth, perhaps the most useful for us is that it is the study which deals with the relation between the earth and life, and particularly human life.

We study this relation for two reasons. The first is because we must. We are wholly dependent on the earth on which we live. There is no other source from which we can obtain food, shelter, clothing, and the other needs of our material life. This is disguised from many of us because we inherit the fruit of the labours of the pioneers, the men who have found out in the course of centuries the best way of using certain of the earth's resources.

Man and the Earth. But the complex life, which in great cities seems to move of itself, depends at bottom on very simple causes. Something, plant or animal, grows somewhere, or is dug out of the earth somewhere; it has to be procured and transported, and modified by human ingenuity, and finally exchanged for some other necessary or luxury of life. All over the world men are striving to make two blades of grass grow where one grew before, to irrigate the desert, to till the waste, to introduce new and superior kinds of plants and animals, so that the world may be better and better able to support its teeming children. Yet all that is being done is but a fraction of what there is to do. New lands are no longer to be sought, yet new trades are waiting for their discoverer, and new sources of wealth to enrich him. We study geography first to learn what the world has to offer to man, how he has used it in the past and present, and how he might use it more profitably still. Till we know a great deal about the world we live in we are, as it were, working in the dark. Knowledge is power.

The Busy Working World. The second reason, out of many we might give, is even better. The more we know of the world the more we are filled with respect and admiration for our fellow men, and the more we desire to be of use to them. We see the Eskimo fashioning out the most skilful weapons from the bones of slain animals, building boats of their hides, lighting and warming himself by burning their fat, supporting himself, and bringing up brave and hardy children. The Indian woman in the western desert, where neither wood nor clay is to be had, patiently gathers dry stringy desert plants, plaiting out of them the baskets, water-bottles, and cooking-pots that she needs. The Chinaman works night and day in his flooded rice fields, knee deep in water, stabbed with rheumatic pains, bent, weary, glad to creep out of the burning sun under the shade of the mulberry trees his thrifty hands have planted along the raised wall of his rice field. The hill peoples of the Himalayan valleys, terracing their hill-sides, ceaselessly carry up soil, basket by basket, when the foaming river below leaves a little uncovered; they bring water by this laborious means and by that, and finally they brighten a tiny patch of the bare hillside with a fruit tree or two, and a little square of golden barley. Who would not be filled with admiration for a race that shows such noble courage and ingenuity under the hardest conditions of life? We cannot think

of men in this way without ourselves becoming kinder and braver, and better fitted for our own battle in life. History and human life take on a new dignity and a new meaning.

The Source of Light and Life. Where, then, are we to begin our study of a world which has developed such wonderful qualities in its sons? With that on which all depends—the relation of our speck of a planet to the great sun round which it moves [4]. If the sun's heat and light were withdrawn but for an hour life, as we know it, would cease to be. The laws which keep the earth in its invisible path round the sun, which bring back in due season day and night, seed time and harvest, are those on which the whole life of the world is built up. On the variations in the heat the earth receives from the sun depends again the whole system of winds and rain; on these the life of plants: on the life of plants the life of animals and man. Every geographer must be in his heart something of a sun-worshipper, and must sympathise with those who have, in various times and places, worshipped it as divine. He will, at least, never forget that by it we live and move, and have our being.

The Planet Earth. The earth on which we live is one of many *planets* surrounding the sun, which is the source of all their light and heat. In shape it approximates closely to a *sphere*, and is generally represented as such. A few people still believe that it is flat. Many considerations, however, show that this is impossible.

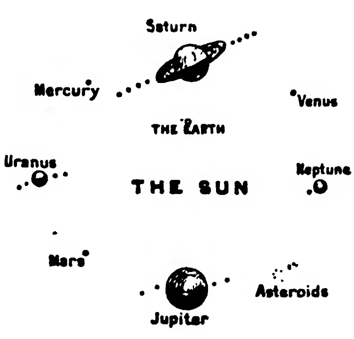
3.



THE SUN & PLANETS

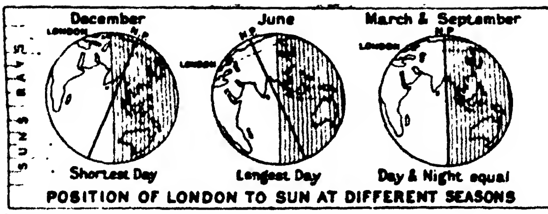
4. SHOWING THEIR COMPARATIVE SIZE.

Perhaps the most convincing is the uniform dip of the horizon at sea, or on a plain [3]. At sea the masts of a ship come into sight while the hull is still hidden by the curve of the earth, so that the ship seems to be sailing up-hill. For the same reason the hull of a receding ship disappears first, and the top of the masts last. On a voyage to our colonies of South Africa and Australia, new stars, which have been hidden by the curved surface of the earth, come into sight, and the familiar constellations disappear over the horizon, or rim of the earth. During an eclipse of the moon the shadow of the earth is outlined on the moon's disc, and it is circular [1.] Finally, the weight of objects is almost uniform at the same height above sea-level at all parts of the earth's surface. This could hardly be the case on a flat earth. Weight results from the pull exercised by the force or attraction known as gravity, or gravitation. If it remains the same it must be because the distance from the centre of attraction remains approximately the same. A figure in which every point on its surface is equally distant from a given centre is a sphere. This implies that the earth is spherical. [For fuller treatment of the subject, see PHYSICS.]

The Earth's Rotation. The earth is not at rest. It revolves round the sun once in 365¼ days, and rotates on its own axis once in twenty-four hours [7]. These two movements give two fixed measures of time, the day and the year, which have been in universal use since the dawn of history. Both movements are of profound importance in fitting the earth to be the home of living creatures. Their nature and consequences must be clearly understood, or our geographical ideas will always be superficial and confused.

Day and Night. The most dramatic of the consequences of *rotation*, the unvarying sequence of day and night, is so impressive that these phenomena are noticed and named by even the lowest races, who often invent grotesque legends to account for what they cannot otherwise explain. What really happens is that the earth is ceaselessly turning in one direction, into the sunlight and out of it. In common language we say that the sun rises and sets. In reality it is always shining, but a particular

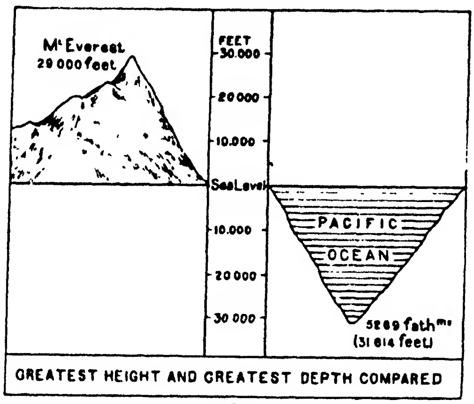
place on the earth's surface has moved into or out of its light. The direction in which the sun comes into sight is called east, the direction in which it disappears, west. The earth, therefore, is rotating from west to east. As it turns, point after point catches sight of the rising sun, and begins its day, while on the opposite side point after point loses sight of the setting sun, and begins its night.



5. SHOWING THE VARYING LENGTHS OF DAY AND NIGHT. [Shaded portion indicates night.]

The first result of rotation, therefore, is that all parts of the world have a share of the sun's light and heat. If the earth did not rotate, one side would always face the sun, and would have perpetual day, and one side would always be turned away, and would have perpetual cold and darkness. Rotation prevents a great part of the earth's surface from being uninhabitable.

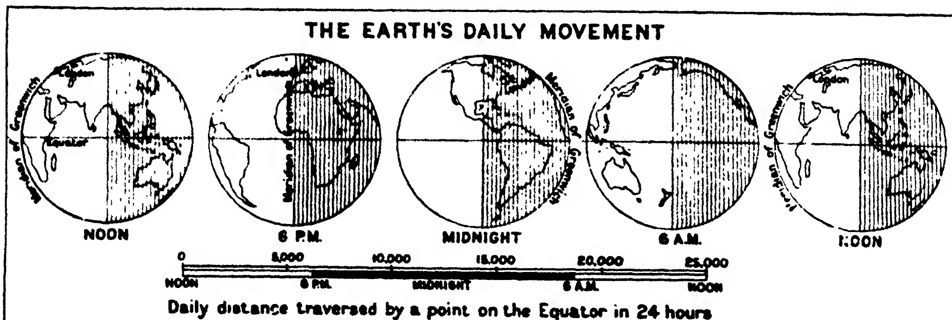
Our Daily Journey. We are so familiar with these facts that we seldom realise how vast a journey we make every day of our lives without being conscious of it. Its actual length depends on the position of our home on the earth. This may be clearer if we think of spinning a top so that it rotates in the same manner as the earth. If we draw on the top a series of parallel circles it will at once be seen that these diminish in circumference from the largest, which is round the middle of the top where it bulges out most, to the extremities. Clearly, a point on the greatest or middle circle makes a longer journey during one rotation than a point on the second circle, and must therefore move quicker. Similarly, a point on the second circle travels further and moves quicker than a point on the third, and so on till we come to the top and bottom, where the circles are reduced to two dead points, for which there is no journey at all, and which are therefore at rest. On the spinning or rotating globe these stationary points, where the earth's movement is reduced to zero, are called the poles. The line joining them is called the axis of rotation. Exactly halfway between the poles we get the greatest circumference, which is represented on our globes or models of the earth by a line called the equator. If the earth were cut through the equator it would be divided into two half spheres, or *hemispheres*, which would be exactly equal. It is hardly necessary to caution the student that the equator is an imaginary line, which is marked on our globes for convenience of measurement [2].



6.

The Earth's Dimensions. Knowing the meaning of the terms pole and equator, we can define the shape of the earth more exactly and estimate its size.

If the earth were a perfect sphere the polar diameter would be exactly equal to the equatorial diameter. This is not the case. The equatorial diameter measures 7,927 miles, the polar diameter only 7,900 miles. We find, too, that objects are slightly heavier at the poles than the equator. This shows that points on the earth's surface at the poles are very slightly nearer to the centre of gravity than points on

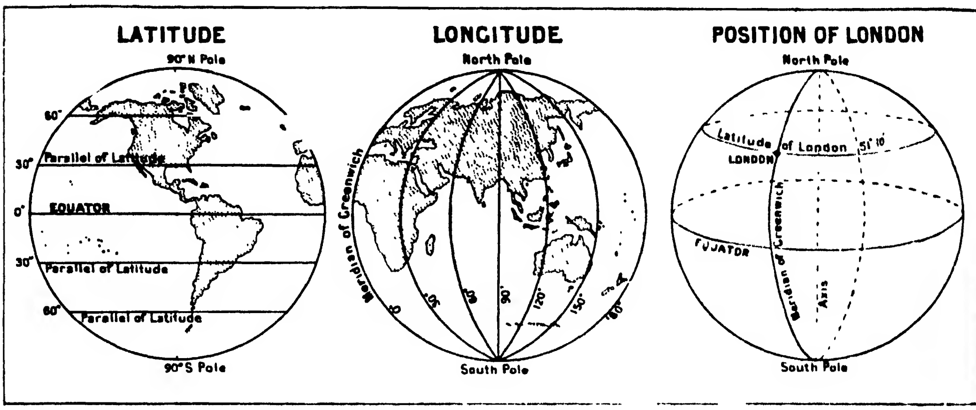


7. [Shaded portion indicates night.]

the surface at the equator, or, in other words, that the earth is very slightly flattened at the poles. Such a figure is called an *oblate spheroid*. The earth's surface is very irregular, pitted, in fact, like the skin of an orange. The highest mountain is about 5½ miles high (29,000 ft.), and the greatest ocean depth is rather more (31,000 ft.). The difference between the two is equal to 12 miles nearly, or half the difference between the polar and equatorial diameters [6].

the horizon, the shadow of a man or a tree points north.*

To fix the position of a place we require, however, more than these general ideas of direction. They are not sufficiently precise. London is south of Edinburgh, but it is north of Paris. For practical purposes the measurements known as *latitude* and *longitude* are employed. Latitude measures distance north or south of the equator. Longitude measures distance east and west of a



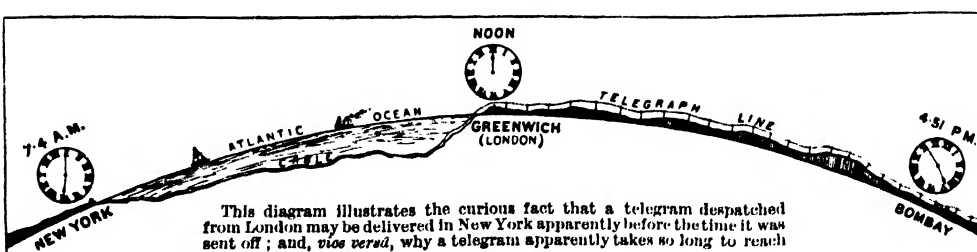
8. EXPLANATION OF LATITUDE AND LONGITUDE, SHOWING HOW THE POSITION OF A PLACE IS DETERMINED ON THE EARTH.

Such irregularities are allowed for in estimating the dimensions of the earth, but no estimate is absolutely correct. The circumference of the earth at the equator is about 25,000 miles. The area of its surface is estimated at 197,000,000 square miles.

Direction and Position. Our first ideas of direction come from the rotation of the earth. The direction in which the sun rises we call east, the direction in which it sets, west. If we stand with the east on our right hand and the west on

line joining the poles and cutting the equator at a known point [8].

Latitude. The circumference of a circle contains 360 degrees, written 360°. The actual value of a degree varies, but it is always $\frac{1}{360}$ of the whole circumference. A semicircle contains 180°; a quarter circle, or quadrant, contains 90°. The distance between pole and equator is a quadrant, or 90°. On a globe we see circles drawn parallel to the equator. These are called parallels of latitude, and they measure the dis-



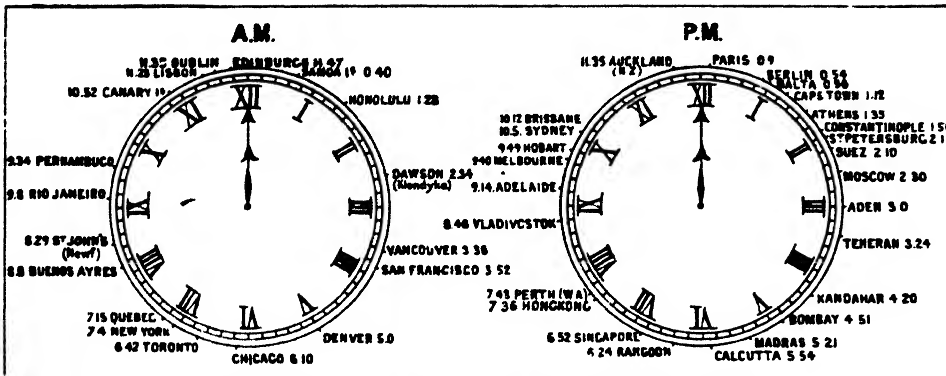
This diagram illustrates the curious fact that a telegram despatched from London may be delivered in New York apparently before the time it was sent off; and, *vice versâ*, why a telegram apparently takes so long to reach Bombay.

9. SIMULTANEOUS TIME AT LONDON, NEW YORK, AND BOMBAY.

our left the direction towards which we face is called north, and the direction to which our back is turned, south. The corresponding poles are the *North Pole* and the *South Pole*. The hemisphere containing the North Pole is the Northern Hemisphere; that containing the South Pole, the Southern Hemisphere. In the northern hemisphere at midday, when the sun is highest above

tance from the equator in degrees. They are numbered from 0° to 90°, the equator being 0°,

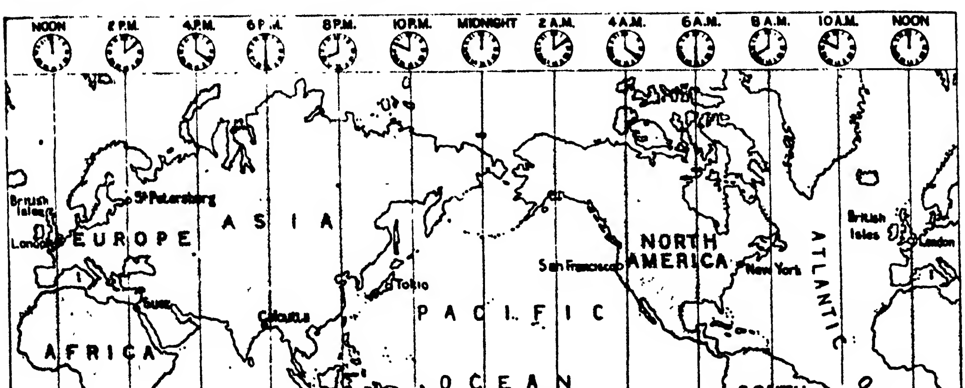
* As we often want to know direction when the sun is not shining, the mariner's compass is used for practical purposes. In its construction use is made of the fact that an iron needle is deflected to the north by the magnetism of the earth [See PHYSICS]. Such a needle is fixed on an indicator, on which thirty-two directions, or points of the compass, are marked.



10 COMPARATIVE TIME WHEN NOON AT GREENWICH

the poles 90°. Whether north or south latitude must also be stated. 90° does not tell us which pole, but 90° N. identifies the North Pole, and 90° S. the South Pole. All points with the same latitude—that is, on the same parallel—are equally distant from the equator. On globes the parallels of latitude are usually drawn for every 5° or 10°, but on large scale maps they may be drawn for every 1°. Distances less than a degree are expressed in minutes, written ′; and seconds, written ″. 1° = 60′ = 60 × 60″ = 3600″.

Longitude. If we know the latitude of a place we do indeed know on which parallel of latitude it lies, but not its position on this parallel. To decide which of all the points on the parallel in question is the one we want we must also know the longitude. In reckoning longitude, or distance east and west, we have nothing corresponding to the equator as a starting-point. Any place may be selected, but Greenwich, which has a famous observatory, is generally taken. A line joining the poles and passing through Greenwich is called the meridian of Greenwich, or the prime meridian, or sometimes the zero meridian. Every point on the prime meridian has the longitude 0°. The point at which it cuts the equator has latitude 0°, longitude 0°—written lat. 0°, long. 0°. From the prime meridian the others are measured and numbered east and west. As there are 360° in a circle, the meridians will run from 0° to 180° E., and from 0° to 180° W., the meridians 180° E. and 180° W. being identical, and passing through the middle of the Pacific Ocean. Now we can locate any point of which we know both the latitude and the longitude. It is the point where the meridian indicated by the longitude cuts the parallel indicated by the latitude.



11. STANDARD TIME ALL OVER THE WORLD.

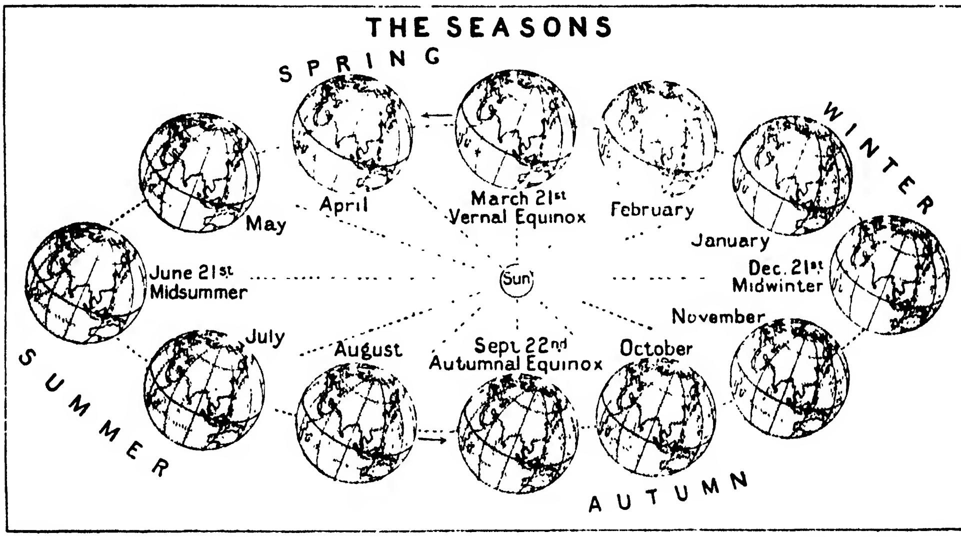
It may be noticed that, while a degree of latitude has always the same value, a degree of longitude decreases from the equator to the poles, to which all the meridians converge. If an orange is skinned the arrangement of its sections illustrates this convergence very prettily.

Measurements of Time. The rotation of the earth enables us to measure time as well as space. The starting-point of our reckoning is noon, the moment when the sun is highest above the horizon. All places on the same meridian—which means midday—have noon, or high sun, at the same moment [11]. The earth rotates through 360° in twenty-four hours—that is, through 15° in an hour. Consequently, when it is noon at Greenwich it is 1 p.m. on the meridian of 15° E. and 11 a.m. on the meridian of 15° W. On the meridian of 30° E. it is 2 p.m., when it is only 10 a.m. on the meridian of 30° W. Similarly it is 3 p.m. on the meridian of 45° E. and 9 a.m. on the meridian of 45° W. On the meridian of 180° it is midnight [10]. Is it midnight to-day, or is it midnight yesterday? Questions of this kind are settled by international agreement. The custom is for a ship sailing eastwards across the Pacific to reckon two consecutive days of the same name as it crosses the meridian of 180°. As the meridian falls in mid-ocean no inconvenience is caused. A ship sailing west drops out a day. Similar agreements are made for changing the hour. Thus, if a traveller from England goes to Belgium his watch will correspond with the Belgian clocks, for these are regulated by Greenwich time. If, however, he goes on to the German frontier the clocks there show mid-European time, by which his watch will be an hour slow. The time thus shown by clocks is called *standard time.* It generally varies more or less from true local or sun time, but it is very convenient to have uniformity of usage [9].

Revolution and its Consequences. The earth revolves round the sun once in a year. The path it traces out, its *orbit*, is an *ellipse*, which brings it in December to a distance of 91½ million miles from the sun, and removes it in June to 94½ million miles. The plane in which this orbit lies is not that of the equator, but the two are inclined at an angle of 23½°. In other words, the axis of rotation is not upright, as in the spinning-top, but tilted. As the earth's axis is always tilted in the same direction, each hemisphere is tilted towards the sun alternately in the course of one revolution. A single glance at the diagram makes this clear [12].

Each hemisphere, therefore, alternately receives a maximum amount of light and heat, and experiences the phenomena known as the seasons. If the axis of the rotating earth were vertical, the rays of the sun would always fall vertically on the equator, which would probably be too hot for human habitation, while most of the other regions which are now densely peopled would certainly be too cold. The inclination of the axis, and the yearly revolution, complete the work of rotation and render nearly the whole of the earth fit for habitation.

The Seasons. Let us now consider carefully the relation of earth and sun throughout a year [5]. On March 21st the sun is vertically overhead at the equator, and the earth presents, as it were, its rim towards it. The sun's rays fall equally towards both poles, which they just reach. Day and night are therefore equal all over the world. This is the *spring* or *vernal equinox*. The earth is now moving into that part of its orbit in which the northern hemisphere is tilted towards the sun. The sun rises daily higher above the horizon in the northern hemisphere, and the days grow longer and warmer. This is the spring of the latitudes north of 23½° N. lat.



12. THE REVOLUTION OF THE EARTH ROUND THE SUN IN EVERY MONTH OF THE YEAR.

BABYLON, THE FIRST PAGE OF DEFINITE HISTORY

By Justin McCarthy

THE dawn of history sometimes appears to generations which have left it long behind as if it were but the dusk of history, with utter darkness growing on. We seem to lose all possibility of bringing ourselves back into association with those periods now submerged in darkness. Then suddenly comes some enterprise of exploration and research, which appears to open for us the very tombs of the past and gives us light by which to study their contents.

The Dawn of History. For some generations the genius of research has been illuminating the earliest records, and in our own time has been making itself more and more manifest. The city of Babylon, the capital of the great Babylonian Empire, has thus been recovered for us from that apparently mythological region to which, for many centuries, it had been consigned. Explorers have discovered buried cities, and the research of qualified scientific and historic scholars has found in the shattered walls and broken pillars of these buried capitals ample and unquestionable records of that place at that period of the world's history. When the ruler of a people is at pains to record on monuments of stone or tablets of metal an account of the events which have happened during his time, we may take it for granted that he did not defy public opinion, even such public opinion as there was in his day, with regard to his authorized description of the events which he saw and had helped to create. Any discoveries made afterwards by historical research have generally tended to confirm the accuracy of these monumental records.

Babylon Re-created. Thus the modern world has been able to re-create the famous city of Babylon, which had been for so long shrouded in legend. Pliny, the Roman historian, born some twenty years after the opening of our Christian era, declared that in his time the site of Babylon was only a desolate wilderness. Early in the eighteenth century European explorers gifted with a scientific and historical intelligence set themselves to study this desolate wilderness, and from that time down to our own days explorations of the same kind and for the same object have been going on. Mr. Rich and Sir R. Ker Porter were among the first who conducted these researches, and more lately Sir Austen Henry Layard, Sir H. Rawlinson, and M. Botta rendered most valuable service to the world by their studies of the rediscovered monuments. Babylon was in its great days the most superb city then found in the world. Its Hanging Gardens appear to have been constructed, each of them, in the form of an amphitheatre, in terraces, one rising above another, and ascended by steps, the whole structure supported by huge arches raised on arches.

Most of the inscriptions carved on the relics which the modern explorers succeeded in discovering were in the cuneiform character. These were translated by Sir Henry Rawlinson and others, and helped to throw much light on the lost history of Babylonia. Sir H. Rawlinson delivered many lectures on the subject at different times in London, and he gave to the British Museum many relics of the greatest historical and archæological value. The Rev. Professor A. H. Sayce delivered lectures on Babylonian literature, and Mr. Robinson Souttar, in his "Short History of Ancient Peoples," published only two years ago, has thrown much light on the history of Babylonia.

The People of Babylon. The region of which Babylon city was the capital lies northwest of the Persian Gulf, bounded on the north by Assyria, and on the west by Arabia. It is a broad flat country, watered by the Euphrates and the Tigris. At one time the soil was rich and well-watered, and had a liberal growth of trees and plants. Babylonia gave evidences of what must be called civilization before any other land except Egypt alone, and Abraham, the parent of the Twelve Tribes of Israel, was by birth a Babylonian. The Babylonians as a people were mainly occupied in agriculture, and they were advanced enough in the principles of civilization to construct a great system of canals, all of

which were used for the purposes of irrigation, while some of them were large enough to be sailed upon by boats, and thus made available for the business of commerce. The people of Babylon were in those distant days entirely devoted to the work of peace. Their subsequent history shows us indeed that, like most other populations who began with peace, they soon drifted into war and efforts at conquest.

A Code of Laws. Mr. Souttar's volume is enriched by an introduction from Professor Sayce, who tells us that, owing to recent research, "We know now that Egypt and Babylonia and Assyria enjoyed a culture and civilization of high order, long centuries before Herodotus or even Homer, and that the elements of Greek culture itself were derived from the East." He tells us, too, that owing to modern researches "in Babylonia, a code of laws had come to light eight centuries older than that of Moses." This code of laws "embodied the decisions of the royal judges in the various cases which for unnumbered generations had been brought before them." So lately as 1902, Professor Sayce tells us that a copy of this code, now deposited in the Louvre, Paris, was found by M. de Morgan "among the ruins of Susa, to which it had been carried as a trophy by an Elamite invader of Babylonia," and that this code "testifies to the existence of a highly-organized and long-established society and to respect for property and law." Again, we are told that "notice is taken even of the operations of a surgeon and a veterinary; if they are successful, the amount of the fee is fixed; if they result in death or blindness, the unskilful practitioner has to submit to punishment."

Babylonian Buildings. We learn that splendid palaces were built, lavishly ornamented with frescoed walls and floors, while the ordinary houses were built with stories and windows like those of a modern day. There were two or three systems of handwriting in use, and it is only in quite recent years that we have come to know of the mere existence of those methods of expression at an age so utterly remote from ours. Modern discovery has, indeed, made it certain that Greece itself was about the same time as Babylonia enjoying a degree of culture and civilization which passed away afterwards and left a blank of long endurance, so that, in fact, the culture which we now regard as identified with the Greece of classic days was but a renaissance in the most distinct sense. "Ancient history is," Professor Sayce tells us, "in truth, being re made in our days, and from time to time it is needful to take stock of the knowledge of it which we have thus far acquired, and to place it before the world."

Babylonia, at the period when it comes into the dawn of history, was apparently inhabited by a mixed race, of the most part Semitic—that is to say, the race claiming to descend from Shem, a Hebrew race in fact. The very earliest of the population, however, seemed to have been Accadian and the earliest cities were of Accadian creation. The antiquity of some of these cities is well established by the style of the cuneiform writing found on their monuments, which evidently belongs to the earliest and rudest days of that writing's development, and also by the nature of the language itself, which is not akin to the Semitic, or Hebrew, but bears greater affinity to the Persian. The earlier inhabitants of the region were soon absorbed in the stronger Semitic race, and the Semitic language became the usual medium of conversation, although the original tongue was for long after kept up as a study by Babylonian scholars.

The Babylonians did not rise to anything like a high level in the character of their religious belief. They were for the most part idolatrous and polytheistic. Astrology and even astronomy were much studied in Babylonia. Their divinities were the Lord of Heaven, the Lord of the Sea, and the Lord of the World, and in lower orders of deities came the gods of the sun and the moon and the air, and several orders of minor deities, some of these only recognised in certain localities. The Babylonian populations had their own sacred books, their collections of hymns, psalms, and even incantations, and different forms of service to be used on the days marked out for the worship of the different deities. They had fast days, and a Sabbath day, which was in itself a strictly religious institution. Among their many legends describing the creation of the world and the deluge was one which set forth the story of the Tower of Babel.

Babylonian Books. The Babylonians were a reading people, and formed many libraries. Their books did not, however, resemble in form or in material the volumes which occupy the shelves of a modern library. Babylonian books were, indeed, sometimes written on papyrus, but, for the most part, they were constructed of clay tablets, on which the writer inscribed his ideas with a letter stylus or pen, while the clay was yet plastic, and then put them for a while to dry and grow hard in the sun. There are not so many material evidences to be found concerning the early history of Babylonia as there are for the early history of Assyria, and this is to be ascribed in great measure to the fact that the Babylonians had but a limited quantity of stone at their disposal in their soft and earthy country-sides, and that they therefore made use of the more readily perishable sun-dried clay for the registration of their history and for their every-day purposes. We know quite enough to make us certain that the Babylonians were a reading people, so far as reading could be accomplished in their time. They were students of astronomy in the practical sense, and they even went so far as to prepare astronomical observations. They divided the firmament into constellations, and to them we owe the introduction of the signs of the Zodiac. The week was divided by them into seven days, and the civilised world has followed their example in this plan for the division of the year into weeks, while the names still retained, which call certain of the days after the sun and the moon, are adopted from the Babylonian method.

The Early History of Babylonia. Our knowledge of Babylonia's early history tells us, as most histories do, of the struggles between rival populations and rulers. Then came a period when Assyria, at first a Babylonian colony, succeeded in conquering Babylonia itself, and then followed the reigns of a number of rulers whose names and whose conjectural history it is not necessary to deal with in this course. Under one of these sovereigns Babylonia became released from the suzerainty of Assyria, and united upper and lower Babylonia under one rule, and then Babylon became the capital of the united people, and remained so for fifteen centuries. One of the greatest sovereigns who ruled over the united Babylonian Empire was Nebuchadnezzar, or, as some historians call him, Nebuchadrezzar. Under his power Babylon became more and more a great city. He reigned for 42 years, and may be said not merely to have rebuilt Babylon, but to have restored almost every temple throughout the country and to have raised many new buildings of the same order.

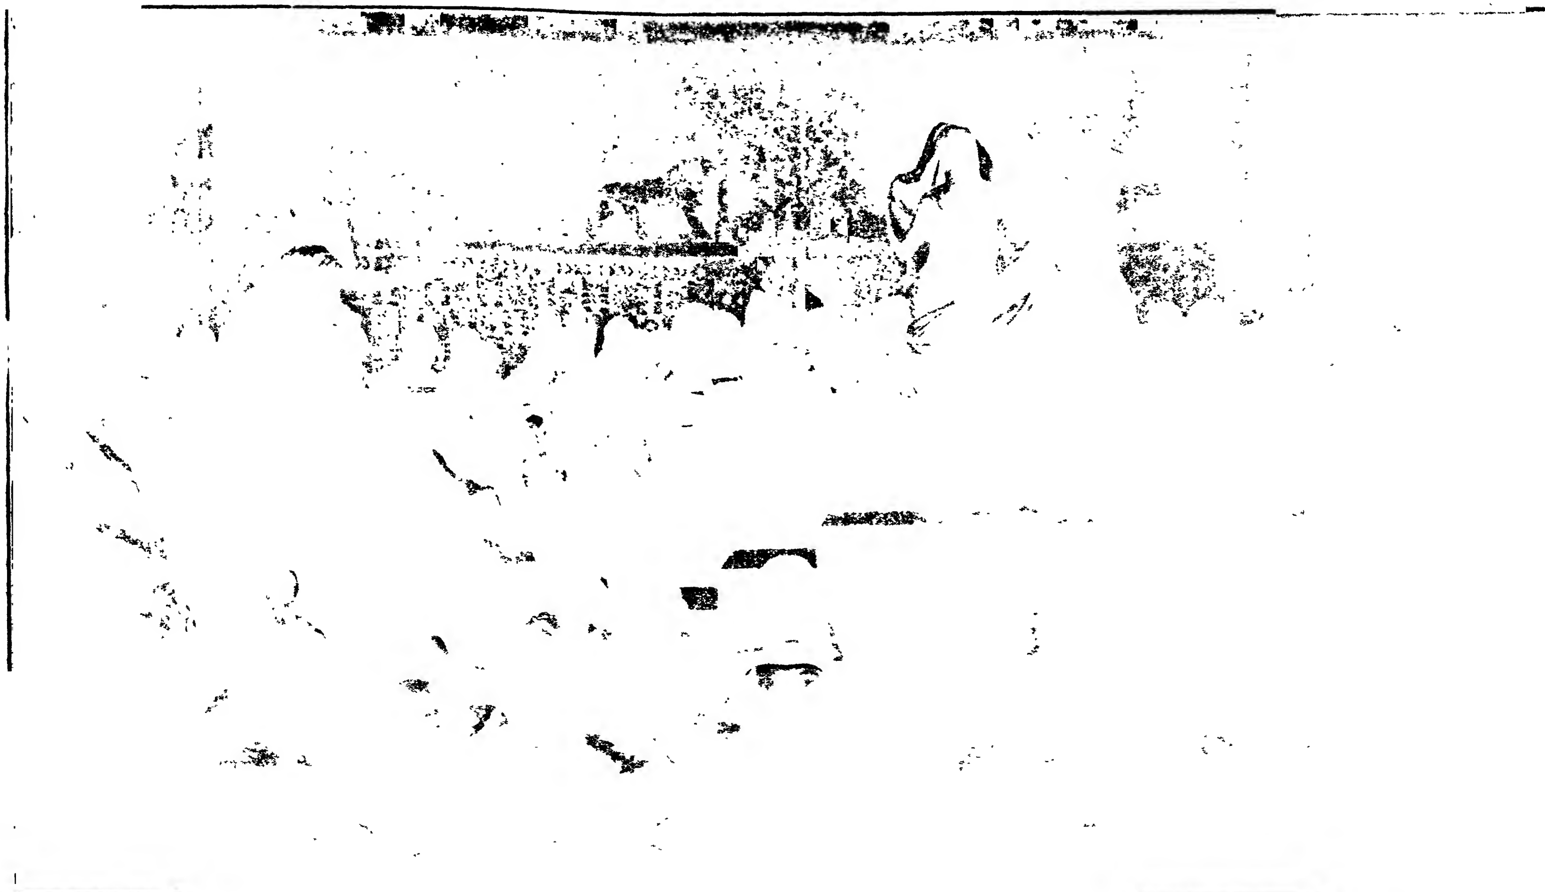
Daniel. We are told that every mound opened by explorers in modern days has contained tablets inscribed with Nebuchadnezzar's name. He was an invader, like most other monarchs of his time, and he afterwards besieged and captured Jerusalem, and later still did his best to devote the city to destruction, and removed many of the Jewish inhabitants to Chaldea. One of those thus removed was the prophet Daniel. For an account of the closing period of Nebuchadnezzar's life we have to look mainly to the records bequeathed by Daniel. The country had then a time of peace, but Nebuchadnezzar himself was for some seven years the victim of a dangerous form of insanity. He recovered at last from this particular affliction, and seems to have come back to his subjects a wiser and a much better man. It would appear that during the short remainder of his life he was able to make himself much admired and trusted by his people, but he did not live long. He died some 560 years before our Christian era, and is said to have been then more than eighty years of age.

A Man Born to be King. Nebuchadnezzar was unquestionably a man of great and varied ability, a man of genius, in fact. He would have been famous as a soldier and a general had he been only a soldier and a general, but he was also an architect of the highest capacity, endowed with much artistic imagination, a thoroughly practical engineer, and a man who might well be described as born to be king. But he was, according to all records, one of the most despotic even among despots. His cruelties to those he had conquered seem to have been sometimes outrageous and wanton, even for that era, when conquest and cruelty generally went together. But he behaved with remarkable kindness to the prophet Daniel, and for a time he actually set up Daniel as something like an object of worship. It is evident, indeed, that he had during his strange and varied career many generous impulses, and had even gleams of an internal light, which now and then seemed to be leading him to a higher form of worship than that which prevailed at his court and throughout his people. During his reign Babylon became a great city covering some 144 square miles of ground, and from its walls arose some 250 towers, while it had 60 gates of bronze picturesquely moulded. The river Euphrates had its course through the middle of the city, where it was crossed by a magnificent bridge of stone, and the bridge had noble embankments, and on each side a superb imperial palace. The care of the ruler extended also to the other parts of his realm. He built many temples in other cities as well as in Babylon, he constructed canals, and also great reservoirs for the important work of irrigation.

The Empire of Nebuchadnezzar. When Nebuchadnezzar's career closed, his Imperial sway had spread to a vast extent, but like other imperial systems constructed after the same fashion, it had to depend altogether on military ambition and military strength and skill to hold it together. That is, indeed, the peculiarity of all monarchies which take under their control several different nationalities subjugated by force of arms. There is no common impulse of loyalty, and when the grip of power relaxes the captives begin to disperse. When Nebuchadnezzar died there was no one qualified to take the place he had maintained, and the empire he had formed began to fall asunder.

The son of Nebuchadnezzar, Evil-Merodach, succeeded to the throne of Babylonia. He seems to have been a man of liberal and merciful spirit, and was much in advance of his age with regard to the toleration of religious creeds and practices differing from his own. It is even said that the indulgence that he showed to the Hebrew religion created alarm and anger among the idol-worshippers of his day, and led to the conspiracy which accomplished his death. That conspiracy was headed by his own brother-in-law, who, after the assassination of the ruler, succeeded to the throne. Evil-Merodach had reigned for only some two years; his successor held for over four years the position which he had won by his crime, and he was followed by the last sovereign of that dynasty, whose reign came to an end within less than twelve months.

The Beginning of the End. Another sovereign, not of the same house but related to it, was ruler of the state for some seventeen years, but during his time Babylonia began to show many evidences of declining power and of relaxing cohesion. The desire of the new sovereign appears to have been to make the city of Babylon not only the centre, but even the sole stronghold of religious and political activity and display. He thus aroused the jealousy and the hostility of the provincial populations. In fact, the whole of Babylonia turned in revolt against him because of the neglect which he had shown for his duties as a sovereign to all the populations outside that of the capital.



19 BABYLON AT THE HEIGHT OF ITS PROSPERITY: "THE BABYLONIAN MARRIAGE MARKET."

From the painting by EDWIN LONG, R.A.

The Rise of New States. In the meantime new states and new combinations of states were forming in the East, and soon began to threaten the now somewhat weakening Babylonia. The Babylonian frontiers had for near neighbours four distinct nationalities. These were the Manda population, a barbaric race sprung from the Scythian invaders; the Medes, who had settled northwards towards the Caspian; the Elamites, living in the eastern mountain ranges, and the Persians, settled on the shores of the Persian Gulf. The Manda had a sovereign ruler, Astyages, of whom history was to hear much, and the King of Elam was Cyrus, of whom history was to hear much more. For a time the sovereign of Babylon and Cyrus would appear to have been on terms of friendly agreement, and both alike looked upon Astyages as a dangerous rival for empire. According to inscriptions found on some tablets dug up in modern days, the ruler of Babylon believed that he had been in a dream inspired by one of his gods to attack the Manda people, and, guided by this dream, he formed an alliance with Cyrus. This alliance led to a war against Astyages, in which Astyages was completely defeated and his dominions were annexed by Cyrus.

The Conquests of Cyrus. *The spirit of conquest carried Cyrus much farther. He became master of Persia, and was received there all the more readily because he claimed descent from the Persian royal family.* After his victory over Astyages, a victory in the results *of which, as in the accomplishment of which, Cyrus assumed the greater part,* he was able to unite under his sovereignty the Elamites, the Persians, the Medes and the Manda. *It soon became evident to the Babylonian sovereign* Nabonidos that, although Cyrus and he had begun in alliance, such a condition of friendship was not likely to last long. Babylonia was already beginning to feel that the alliance with Cyrus was not much to be depended on. She was about to form an alliance with Crœsus, the sovereign of the Lydians, but Cyrus, understanding probably how things were going, invaded Lydia before the ruler of Babylon could intervene. The result of the struggle between Cyrus and the Lydian monarch seemed uncertain in the first battle, but Cyrus, with the instinct of conquest, continued his movements so rapidly and so effectively that he completely defeated his opponent and captured his capital. **Cyrus now had stretched his rule from the Caspian Sea to the Mediterranean, and he then began at once an invasion of Babylonia on the north. His first attempt was not successful, as the fortifications of Babylon were powerful, but, as we have already said, there was much disaffection among the populations under the rule of Nabonidos, many of whom were actually foreigners forced into Babylonia by some of its former rulers. These foreign populations were willing to support the intervention of any new invader, and the army of Cyrus won a complete victory over the Babylonian King. Thereupon the second city in Babylonia, Sippara, surrendered to the invader without putting him to the trouble of accomplishing its capture by force of arms.**

New Ruler of Babylonia. This event proved to be practically decisive of the struggle, for Babylon soon after made its surrender to the conqueror. Nabonidos was made a prisoner, and kept in chains for some months, after which he died, or, in all probability, was actually put to death in prison. Cyrus was now the recognised ruler of the country, for the son of Nabonidos, Belshazzar, had fallen in battle, or been put to death. Cyrus had evidently much of the genius of a ruler, and he did his best to make himself acceptable to the Babylonians. He reversed the policy which had been making Babylon the seat of all authority, and of all recognised position, by restoring the provincial cities to their full share of influence, and by inviting exiled Babylonians to return to their natural home. He was *also systematically tolerant to differences of religious faith, and he was friendly and liberal towards the Hebrews. Babylonia finally* became a part of the Persian Empire, and its history thus becomes mingled with that of Greece, as we shall see in another part of this course. In later days the city of Babylon passed out of living existence, until "only mounds of rubbish remained to mark the site it had once occupied" in such splendour and power. The Babylon of which we now know so much has, therefore, been restored to the world's history by the energy, the intellect, and the keen scrutiny of modern explorers, archæologists, and scholars, most, if not all of them, coming from seats of European education. It was in its great days a centre of power, of intellect, and of art; it is now but a memory and a fame.

THE PRACTICAL TRAINING OF THE YOUNG FARMER

By Professor James Long

AGRICULTURE is the term which is applied to the cultivation of the soil and the crops which grow upon it.

Its successful practice depends upon knowledge acquired by study, experience, and industry. In the long past no special form of instruction was provided for young men and women who were intended for a life on the land. The son learnt his business from the father and the men whom he employed, and by going to plough on the smaller holdings as soon as he became able, and taking his place as a labourer with a prospect of succession as tenant or owner. And so with the daughter, who learned from her mother the practice of milking, butter and cheesemaking, and poultry-rearing, in addition to those varied household arts—baking, preserving, curing, and the like—which present her as such an agreeable contrast with her successors of to-day.

The Products of the Soil. The education of our ancestors in relation to our great industry was, indeed, empirical. Science had not placed her finger upon the weak points which restrained the most progressive and far-seeing farmers, and it was not until it had extracted from Nature some of her most valued secrets that old theories and practices were exploded, and man was shown how beautifully and perfectly the Creator has provided for the production, through the medium of the soil, of all that man requires for his material comfort and support.

While we depend upon the soil for all we need, whether it be food or clothing, for the construction of our homes, for the maintenance of our warmth in winter and protection against the heat of the summer's sun, we also depend upon the rain and the atmosphere. Whatever may have been the origin of animals and plants, we know that to-day the former depend upon the latter for their maintenance, and that in a large measure the latter depend upon the former. As between the two kingdoms Nature works in a cycle; the plant feeds the animal, which returns to the soil as manure what it does not utilise, this embracing a large proportion of those plant-feeding materials which have been extracted from it, so that its fertility is in large part maintained. Where crops are grown and entirely removed—where, in fact, no such return is made, the soil gradually but surely loses fertility, and in our modern system of high culture, where the feeding of the soil is confined solely to a return of the dung which its crops have produced, it is still, if less rapidly, impoverished, and really successful cropping becomes impossible. It is where the soil receives more than is removed from it—whether through manure produced by animals, whose rations have been enriched by foods, such as cakes and grain imported on to the farm, or by the addition of what are known as chemical or artificial manures—that progress is made, and the crops are increased in weight and value.

"Intensive Culture." It is practically this system of feeding the soil, combined with thorough working, which is known as "inten-

sive culture." What foods it is most desirable to purchase or to grow for the successful feeding of stock, and what manures it is most profitable to employ for the sustenance of particular crops, it is for the farmer to ascertain, and, happily, at the commencement of the twentieth century he is able to learn gratuitously and from many sources precisely how to act in each case. His ancestors possessed few of the advantages which are placed to-day at his disposal. Many of the most valued concentrated foods, and those we chiefly import, were unknown, whereas the chemical fertiliser, which plays such a masterly part in the agricultural system of all enlightened countries, like the principles upon which its employment is founded, was but a dream, and that only in the case of a handful of prescient and enlightened men.

sugar, both of which, like the oil of plants which in the grain of linseed forms 37 per cent. of its total weight, are rich in carbon. Plants obtain their carbon from the atmosphere by the absorption, in the presence of sunlight, of carbonic acid, which they decompose, liberating its oxygen in the process. Carbonic acid forms but a very small proportion of the atmosphere, which chiefly consists of nitrogen and oxygen, but that proportion is maintained by what is returned to it by the exhalation of animals as one of the products of their respiration.

In the British Islands agriculture is practically confined to various forms of mixed culture. There are farms which entirely consist of grass, but in such cases, if success is to be achieved, the occupiers must either employ purchased foods for the more generous feeding of their stock, or

A CHAMPION SHORTHORN BULL.
The property of Mr. Robert Taylor, Pitlivie, Carnoustie, N.B.

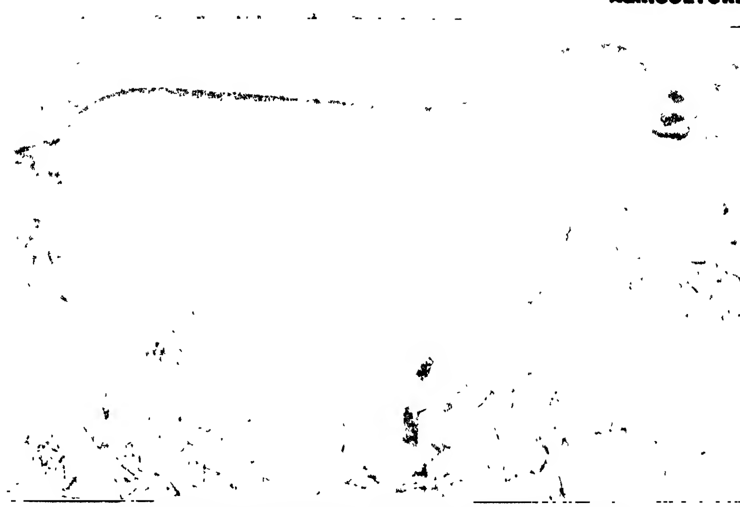
We depend upon the rain for a variety of reasons, and among them the following, which, perhaps, may be regarded as the most important. Water is essential to plants, inasmuch as it forms the largest portion of their composition, 14 per cent. in the case of the wheat-grain to 90 per cent. in the turnip. It is, too, the medium by which the mineral matter of the soil is conveyed to the plant and appropriated in the formation of its structure. Without water tillage would be impossible, and seed, if deposited, would be unable to germinate.

The Atmosphere. The atmosphere is also as essential to plant as to animal life, although for different reasons. The feeding materials of plants which are in greatest abundance are those which are known as the carbohydrates, chiefly consisting of starch and

where stock are neither fed nor bred and the crops are sold—and this would be a practice as unwise as it is uncommon—they must purchase manure to a considerable extent, and at a cost which would not be commensurate with the results.

The Rotation of Crops. Progressive farming, as it is now understood, entails what is known as the rotation of crops. It is true that by intensive culture and perfect cleanliness—by which we mean entire freedom from weeds—the same crops can in many cases be grown year after year upon the same soil, but owing to the inherent necessity for variety which is involved in the breeding and feeding of stock, the farmer finds it to his advantage to grow crops of various kinds, and by their assistance, the one helping the other, to

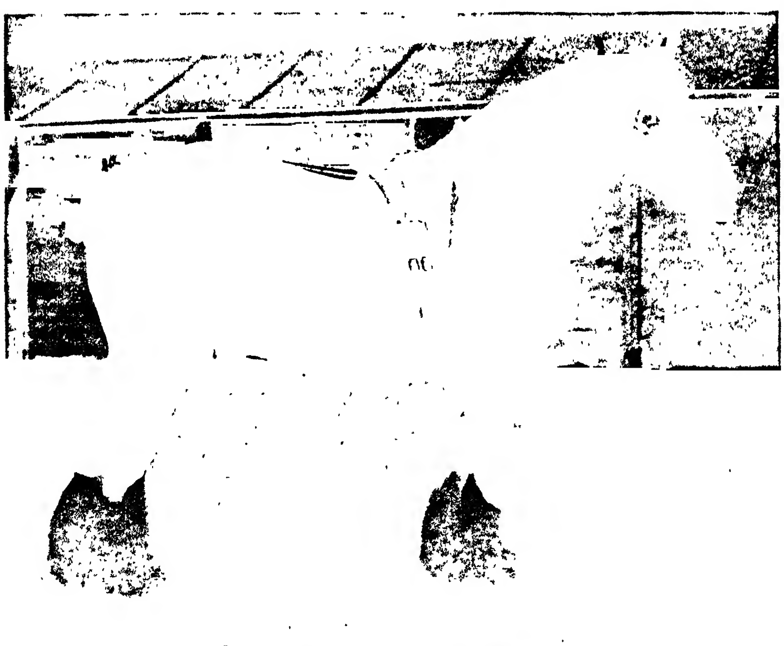
maintain cleanliness and at the same time to husband and even impart fertility. Root cultivation and destruction of weeds, which processes are applied to the mangel and turnip, as well as the system of manuring which is followed for their benefit, prepares the way for grain and pulse, for clovers and artificial grasses. In their turn the clovers and their leguminous allies, by the absorption of the nitrogen of the atmosphere, which takes place through the action of the bacteria which are found in the tiny nodules on their roots, enrich the soil with that element which is most of all essential to the prosperity of the cereals and of many other important plants.



A CHAMPION SOUTHDOWN RAM AT THE ROYAL SHOW.
The property of the King.

Systems of Farming. Our forefathers were aware that a clover crop was a good preparation for wheat and other grain crops, but they were unable to understand why it was possible to remove heavy crops of clover from the land, involving the loss of large quantities of plant food, and, therefore, apparently diminishing its fertility, and yet to obtain, what seemed contrary to Nature, larger crops of grain in succession than would otherwise have been the case. We now know that the chief element of fertility removed in clover, as in all similar plants, is nitrogen, as already suggested, but that a large proportion of the nitrogen absorbed still remains in the roots, which on decomposing provide a succeeding crop with a liberal supply.

Farming in the British Islands is conducted on diverse systems, all depending, apart from the inclinations of the cultivator, who, however, is largely controlled by Nature, upon soil and climate. Nevertheless, we may take one county — Yorkshire—as a type of England, for here we find systems as opposite in character as sand is to clay—sheep-farming on the Wolds in the East Riding, grain and pulse in Holderness, potato culture in the Vale of York, dairy farming



A CHAMPION SHIRE STALLION, DELAMERE CHORISTER.

and grazing on the pastures of the West Riding, and the production of cattle in the North. If we would ascertain the influence of the rainfall we have only to look to East Anglia, where in consequence of its small percentage, cereals are chiefly grown, and to the western counties, whether Cumberland or Westmoreland, Devon or Somerset, where it is high, and where, as a result, pasture farming, the production of hay, and the grazing of stock is the dominant practice.

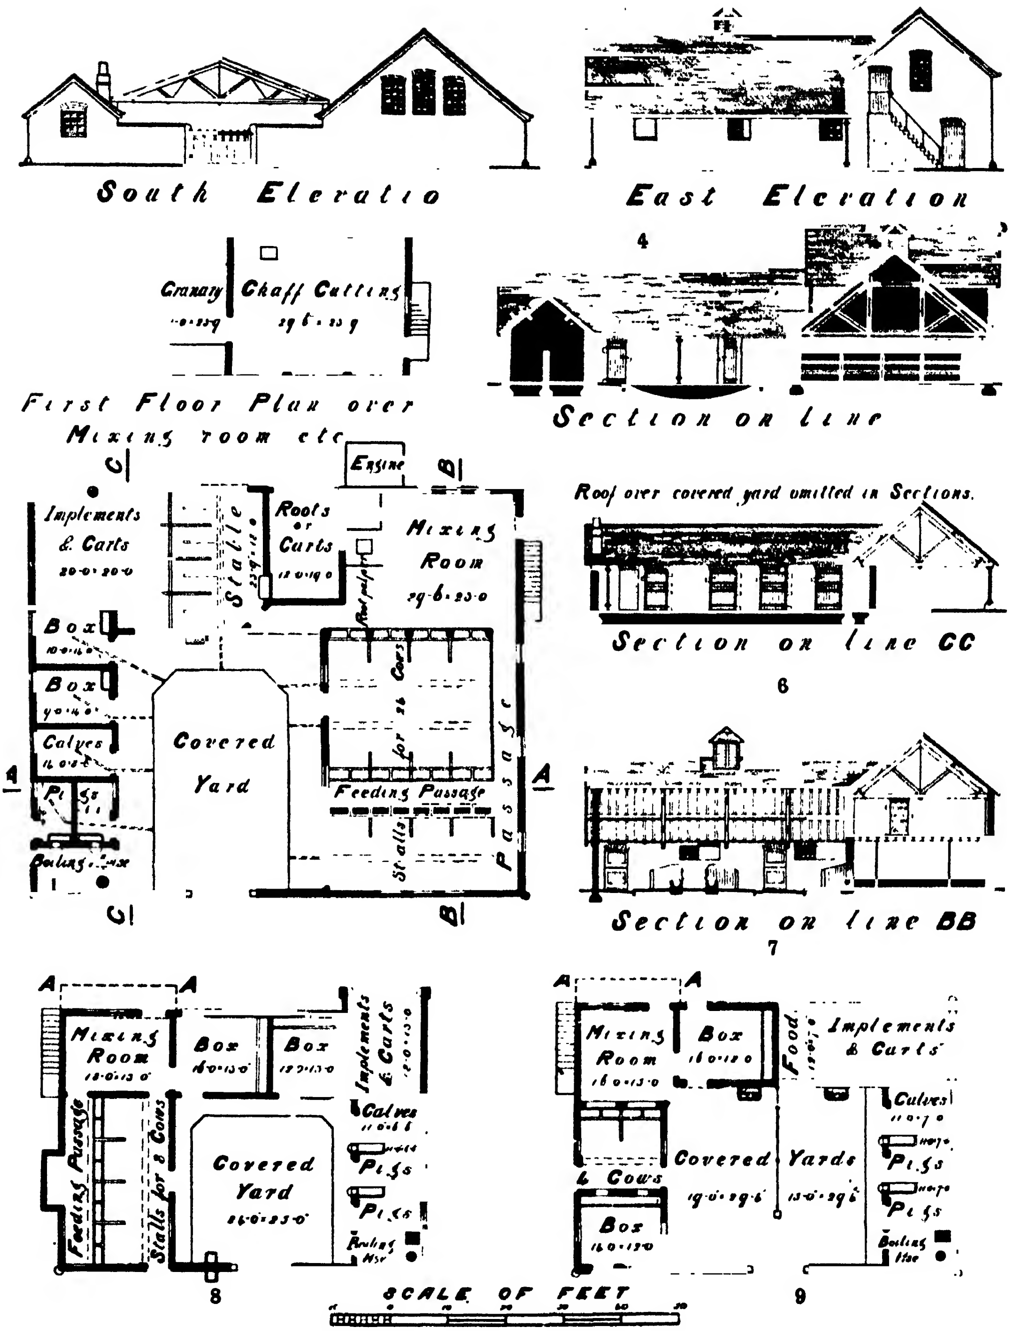
Sizes of Farms. In England, but for other reasons than those of soil and climate, the size of the farms is larger than in any other old and highly-civilised agricultural country; for example, the average area of the English farm is about 63 acres; in other countries, chiefly owing to the fact that the land is much more extensively owned by the people, the average size of each holding is much smaller. In France the average area is 15¼; in Germany 76 per cent. of the farms are under 12½ acres, in Belgium 715,000 farmers each occupy less than 10 acres, while in Denmark 161,000 farms are under 25 acres in extent. In Holland 79,000 farms out of 169,000 are under 12½ acres, while 143,000 are under 50 acres. The larger the area the larger the capital essential for the purpose of stocking and equipment; thus, while the English farmer chiefly employs his capital in the provision of live and dead stock, the Continental farmer employs it in land, and for this reason he is the chief factor or backbone of his particular country. Capital is essential for the successful cultivation of land. There is no system which is so advantageous as that under which stock and crops are made interdependent upon each other.

The Farmer's Beginnings. It will be apparent that the young farmer should thoroughly understand the principles by which the cultivation of the soil and the breeding and feeding of stock are governed. To imitate the practice of his father, valuable up to a certain point, is insufficient. He must learn, through knowledge of the influence of climate and of the soil in its various forms, how far he may take advantage of those crops and those classes of stock which have hitherto been strange to the land he occupies. This knowledge is especially valuable in the selection of a farm as well as in its improvement. He will naturally consider not only what has been accomplished by his predecessor, but how far that predecessor has failed for want of information. He will look for land to which the sun has constant access, to perfect drainage, to a general and constant water-supply, to substantial and easily maintained hedges or fences, to good roads, to access to market and rail, to convenient, simple, easily maintained and not too extensive buildings; to a healthy home, pure water for his consumption, and perfect sanitation. He will take care to learn not only how to buy stock foods and manures to the greatest advantage, but what and how to supply them to the stock and crops on his farm.

UNIVERSAL AGRICULTURAL MOTOR AT WORK: ATTACHED TO A SELF-BINDER.

Science and Practice. The improvement of a farm, whether it be naturally poor, or poor as the result of carelessness or bad workmanship, depends as much upon the knowledge, which is the result of latter-day investigation, as upon the practical experience of the cultivator. An improved farm returns larger crops and feeds more cattle than hitherto, and, therefore, it should produce a larger profit. Improvement, however, does not depend solely upon the cleaning of the land, the destruction of weeds, and liberal and judicious manuring, but also upon the deepening of the tilth by the plough, where, it may be for generations, it has never penetrated beyond a given depth, and that a superficial one; upon the variations of the crops by the introduction of those plants which under modern or advanced culture are now grown with success, and upon the feeding of a larger head of improved stock.

Average Yield of Crops. Again, the young farmer should make himself acquainted, not only with the average yield of each crop grown in this country, and especially of those



THE ARRANGEMENT OF A SMALL FARM OR A SMALL HOLDING

A decisive factor in farming is the arrangement and maintenance of outbuildings. The chief design on this page has been carefully worked out to meet, at the smallest possible cost, all the requirements of a farm of from 80 to 120 acres; and the smaller plans are for a small holding of from 30 to 60 acres.

The plan for the farm provides for stalls for 24 cows in the east wing; calves, pigs, and boxes occupying the west, with a convenient covered yard between the two. On the north side are stables, sheds and stores, with chambers over.

Fig. 8 shows designs well adapted to a small holding of from 30 to 60 acres, with milk production as its staple business, and 9 is a plan for a similar holding on which milk production and cattle-raising are combined.

These plans, based on the experience of 40 years of farm life, are by Mr. Samuel Taylor, Government Medallist in the Science and Practice of Agriculture, who has been awarded the Medal of Merit of the British Dairy Farmers' Association for the design of farm homesteads.

adapted to his own holding, but he should learn what is the possible yield of each under high cultivation. A study of a question like this may provide an incentive which may prove most serviceable. He may be inspired with a desire to emulate those who have succeeded far beyond their fellows, and who shall say that he may not equal their performances? The average yield of wheat, less than 4 quarters—or nearly 32 bushels—to the acre, and of oats, 39 bushels, is easily excelled on suitable soils—and this must always be an essential qualification—by the farmer who is thoroughly proficient, and whether we take the potato or the mangel crop, grass or clover, or, indeed, any plant or plants which are common to the farm, we shall find that the same argument applies. The average man obtains an average return; the tenant who has mistaken his vocation, and who was better adapted for some other form of industry, makes little or no praiseworthy attempt to excel whatever.

Training. How then should the young men who are the prospective farmers of the future be trained for prosperous life work? There are many who believe that a course of study at an Agricultural College is sufficient. There are others who regard it as imperative that they should take an active part in the practical work of the farm which is occupied by their fathers, and that nothing further is needed. Others, again, recommend a form of practical pupilage on the farm of a highly-skilled agriculturist. In neither case are these proposals sufficient for the purpose. Of the two we should prefer the man who had passed through a practical course of work on a farm rather than the student whose sole acquaintance with farming had been gained at an Agricultural College. Farmers have succeeded in the past, and will succeed in the future, without the advantage of scientific knowledge, although in many cases their observations possessed a scientific basis.

An acquaintance with the theory of agriculture and with those sciences upon which its principles are based is not sufficient to enable a man to conduct a farm with success. It must be remembered that successful farming involves the management of men, a personal acquaintance with the soil and power to judge of its condition under varying circumstances, a recognition of the character and quality of plants for the very necessary purposes of sowing and growing in suitable soils and climates, of harvesting at the right moment, and of selling to the best advantage. A farmer should be able to deal advantageously with his fellow-men, be he corn-merchant or butcher, stock-dealer or maltster; indeed, in a hundred ways he needs a form of practical training which is only possible on the farm, in the market, or on the corn exchange.

Scientific Education. A course of preparation for a farming career should include scientific as well as practical education in its various aspects. A lad who goes straight from school to an Agricultural College is not prepared for the work of which it is intended he should obtain a grip. He will be taught facts relating to soil, crops, and animals, of which, in all probability, he knows little or nothing: and at the close of his academic career he may be crammed with a form of knowledge valuable under other conditions, but which he is unable to apply in his daily life.

Far different is it with the lad of slightly more advanced years, who has spent two or three seasons upon the land, and taken part in all the varied forms of labour which its cultivation and the management of stock involves. He has reached a period of life when his receptive powers are active, and he rapidly learns to manage the implements and machines which are employed and the horses which draw them. He fully acquaints himself with the habits of livestock in all their varieties; with their requirements and with the methods of feeding which are employed. He obtains many hints from the workmen, with whose habits he becomes intimate. He enjoys attending the markets and fairs, the corn exchange, and the auction, and he gradually acquires a fund of information which is impossible under any form of scholastic training. Such a lad is in a position to take advantage of a course of instruction at an Agricultural College, and a couple of years, so far from being wasted, will, unless he is a dullard and utterly unwilling to work, be followed by a fairly comprehensive grasp in successful practice on the farm, of those scientific facts which explain the "reason why," and of those principles which once understood provide a foundation for a successful future.

Scientific knowledge, however, not only explains why certain practices are followed and results obtained, but it suggests; and under almost all circumstances it enables a thinking man who is at the same time a good practitioner to vary or to modify any part of his system, which is not precisely as prosperous as it might be, for the reason that he knows the cause and is in a position to suggest a remedy.

The Farm as a School. We do not for one moment despise the teaching which a farmer's son receives under his father's eye. It is well that he should begin his career at home, and learn the elements of practice and the necessity for a personal acquaintance with every form of farm labour before he commences his college course, which is in these days an almost imperative necessity.

That course completed, he may most advantageously spend six to twelve months upon each of two farms in different parts of the country where the work is of the highest class, where the soil and the climate differ, and where the crops and stock enable him to learn facts and to acquire a knowledge of practices which he has been unable to learn elsewhere, but which will provide him with a larger fund of information, and thus enable him to become less dependent upon local customs and conditions, climate and soil.

THE BEGINNINGS OF LIFE AND THE STUDY OF BIOLOGY

By Dr. Gerald Leighton

THE cultured man who sets out to learn what is known concerning the Science of Life is entering upon a subject whose scope is unlimited, because the subject is the largest in the world. If it be true that the proper study for mankind is Man, it follows that the investigation of the methods and principles by the operation of which Man has become the creature he is will embrace the most fascinating topics open to his research.

The very vastness of the subject is, however, a disadvantage. The serious student of Biology finds that the devotion of a life-time is hardly sufficient for him to familiarise himself with all that is to be learnt about one single branch of the subject. The great mass of this knowledge has been accumulated since the epoch-making work of Charles Darwin, whose observations and deductions opened up the way to fields of work and thought previously undreamed of. It is but the bare truth, indeed, to say that modern biological science dates from the publication of the "Origin of Species."

The Vastness of the Science. The inevitable result of this rapid accumulation of facts concerning the science of life was that it very soon became necessary for students to take up special branches of biology to the neglect of other branches, and at the present day any one of the various branches of the science provides material for a life's work. It is possible, indeed it is usual, for the expert in plant life to be quite ignorant of all that concerns the life of, say, a fish.

It cannot be otherwise. The biologist of to-day, if he is to add anything to the sum of human knowledge, must specialise; he must confine his studies to the life-history of a few types of life, or even to a single family or species. But, in order that he may do this to the best advantage, it is first of all very necessary that he should have a clear conception of all the great principles which govern the life of any kind of living organism. The danger of specialisation is that these great principles are apt to be lost sight of in a mass of minute detail. It is difficult to see all the facts of life in their true proportion when the mind's eye is constantly focussed upon a special point.

Phenomenon of Life. Now, as far as the man of culture is concerned, these minute details are of no importance: they do not help him to understand the problems of life, nor do they throw any light upon the ages that are gone. In order that they may be of any use to him these details require to be generalised, taken out of their special compartment of scientific knowledge and put in their place along with other facts of a similar kind, the whole sum of which point to the existence of a universal or general law. When, after years of specialised labour, sufficient data have been accumulated upon which it is safe to deduce general laws or principles, *then and then only is it time for a science to be included in any general scheme of education.*

The Science of Life—Biology—has reached that stage. It is no longer possible for any man to claim to be considered educated or cultured if he remains in ignorance of the great Laws of Biology. Without being either a botanist or a zoologist it is open to every man nowadays to learn much of how the world of living creatures has become what he sees it to be. It is not only possible; it is essential. There is no other way in which we can see the true proportion of things, there is no other way to "see Life whole."

Our object here is, therefore, to endeavour to gain a broad and comprehensive view of the most marvellous phenomenon of which we have any knowledge—the phenomenon of Life. And since, of all forms of life, that which is of supreme interest to man is his own life, we shall try to trace the means whereby a creature has been produced capable of undertaking the task of investigating himself. In order to do this, it will be necessary to go back to the simplest forms of life that are known, to see how they live and move and have their being, to study the various aspects of *their* life, to see how it became more complex according to changing surroundings, to explain why some things survived while others perished, and to discover how the survivors transmitted their priceless advantages to succeeding generations.

Life in its Simplest Forms. The important point to note at the outset is that, just as the simplest forms of life are single cells which perform all the functions necessary to life before any specialisation of function appears, so in the study of these phenomena must the student begin with what is general before attempting to study the special. Our attempt, then, is to trace life from its simplest forms, through its branchings and modes of transmission, to its highest development as manifested in the flight of a bird, the speed of a racehorse, the character and mind of Man.

Nature yields up her secrets unwillingly, and the secret of the nature of life has been inscrutably kept. We do not know what Life is. But we know what is *meant* by saying that an organism is living, and that definition is as far as we can go. We mean by Life that state of an animal, or plant, in which its organs are capable of performing their functions, or in which the performance of those functions has not permanently ceased. What we mean by Life is a series of definite and successive changes, both of structure and composition, which take place within an individual without destroying its identity. That is *what we mean*. Of the actual nature or essence of those changes we remain ignorant. No plausible or reasonable explanation has ever been put forward to account for the phenomenon of Life entering into non-living matter. We are utterly ignorant of how Life came to be.

Things that Cannot be Proved. Let it be carefully noted that we are speaking now of knowledge, not of beliefs. That is a distinction to be constantly kept in mind in dealing with science. *It is one thing to believe that a certain fact occurred, or that a certain process took place; it is quite a different thing to know it. One may believe many things, and they may be perfectly true, without its being possible to prove their truth.* The mental attitude in relation to such matters will be found to be mainly a matter of individual temperament. On matters which cannot be definitely proved one man will adopt the attitude of belief, another will be inclined to deny, whilst a cautious third will be content with asserting his ignorance. The one should have no cause of quarrel with the other. An unproved and unprovable dogmatic statement is helpful to some types of minds; it is a positive hindrance to others.

"How?" To many minds the question "How?" is non-existent. It does not present itself to them as a difficulty to be solved before they can believe. They have simple Faith. But one of the results of the evolution of the higher mental character of man has been to produce a speculative type of mind. Such a mind is not content with a bare dogmatic statement. "How?" is to it the one supremely interesting question. It seeks to account for processes by formulating theories based on facts. So long as the distinction between the attitude of belief and that of knowledge is kept clear, there is no cause, let us repeat, for quarrel between the two.

It is to the ever-growing spirit of research and curiosity that all progress of scientific thought is due, and so much light has been thrown upon the problems of life in the last fifty years that much which to our fathers was obscure is now becoming clear. But as regards the Origin of Life we are still without an explanation.

The reason is that this phenomenon stands alone. There is nothing else quite like it, or with which it can be compared. A hard and fast line seems to mark off the living from the non-living; there is no sign of the process by which the gulf could have been bridged in the first place. It is true that a theory known as that of Spontaneous Generation has been advanced to account for the origin of life, but it merely asserts that living matter arose from non-living, without explaining how. Spontaneous generation asserts the possibility of producing a living organism without the necessity of a pre-existing parent.

The Origin of Life. In the seventeenth century this was the prevailing view amongst naturalists and men of science, and it was sanctioned by antiquity. Its first assailant was Redi, an Italian philosopher. Needham and Buffon, both of whom have been commonly regarded as supporters of the hypothesis, held it in a modified way. "They held that life is the indefeasible property of certain indestructible molecules of matter which exist in all living things, and have inherent activities by which they are distinguished from non-living matter; each individual living organism being *formed by their temporary combination*, and they standing to it in the relation of the particles of water to a cascade or a whirlpool, or to a mould, into which the water is poured."

The doctrine of spontaneous generation is now held, oddly enough, by extreme evolutionists, under the name of Abiogenesis. A belief in abiogenesis means, simply, that at some period in the history of the universe there must have been a time and a process which resulted in the transformation of non-living matter into living protoplasm. It further involves the belief that this was a natural process and not the result of "supernatural" or "miraculous" interference. Biogenesis, on the other hand, as

maintained by Redi, is the belief that living organisms can spring only from pre-existing living parents. During the last half-century the belief in spontaneous generation largely lapsed, mainly on account of the work of Tyndall, Pasteur, and others. The present attitude of science in regard to this theory may be described as a reserved scepticism, the agnostic view, which does not deny the possibility of spontaneous generation or abiogenesis in some other and remote period of the world's history, but, reasoning from the failure of all experiments in that direction, is inclined to think that life *now* is produced only from life.

An Important Fact. The important fact for us to realise here is that living cells have the power of converting non-living matter into living protoplasm. "The simple constituents of the food are converted *step by step into the living substance of the plant by the agency of that substance itself.*"

Passing now from all speculation as to the origin of life, let us turn to the facts as they may be seen and studied in plants and animals, limiting ourselves to the description of a few of the principal types of animals, a knowledge of whose general plan of structure and mode of life every educated man should possess. For the rest, our object is to bring before the reader the great biological laws which have produced these creatures, and to endeavour to ascertain in what directions these laws are operating now. We shall begin with the higher forms and end with the lower, because most people know something of the anatomy and physiology of man, and also because those subjects are fully treated in PHYSIOLOGY. It will be presumed in what follows that the reader has made himself familiar, through other sections of this work, with the structure and functions of Man.

The Groups of Animals. The first scientific attempt to arrange animals in groups according to types was that of Aristotle (384–322 B.C.), who clearly recognised the fact that the whole animal kingdom represents a gradual transition from lower to higher forms. He also recognised that structure must be taken as the basis of classification. He therefore divided animals into two great groups, which correspond exactly with the modern division into Vertebrates and Invertebrates.

The great object of systematic classification is accuracy of description and convenience of reference. It is simply a means to an end. *It is arrived at by noting likenesses and differences. In this way the whole realm of animate life is divided into the two great groups of* **Plants and Animals.** The broad distinctions between these two are plain enough, but it is sometimes difficult, or even impossible, to say whether a given organism is to be regarded as a plant or an animal, or neither.

Taking first the Vertebrates, or back-boned animals, we find that there are five well-defined groups, viz., Mammals, Birds, Reptiles, Amphibians, and Fishes.

Essential Characters of Vertebrates. The description in PHYSIOLOGY of the structure and functions of Man gives an idea of the principal characteristics of the whole group, but we may summarise the essential characters of Vertebrates here. All possess a vertebral column or back-bone, from which the group takes its name. The body is bilaterally symmetrical always in the young animal, and generally in the adult. There is no obvious external division of the body into segments, but the internal structure indicates such a division. A longitudinal section through the body (such as may be seen in the carcase of a sheep in a butcher's shop) shows that it is made up of two tubes. One tube is dorsal, the other ventral. The dorsal tube consists of a narrow canal in the back-bone, which encloses the spinal cord, and this widens out into the larger cavity of the skull in which lies the brain. The ventral tube forms the cavity of the chest and abdomen, and contains the organs of those parts. Most vertebrates have limbs, and these are never more in number than two pairs. Of all these characters one of the most obvious and important is the enclosure of the nervous system in its own bony tube, separated from the rest of the body.

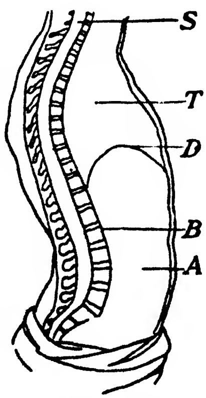
This double tube arrangement is a primary distinction between Vertebrates and Invertebrates, because in the latter, in all adults without exception, the body may be regarded as a *single* tube, which encloses all the viscera, and the nervous system is enclosed within the general body cavity, and is not in any way shut off. The contrast is well brought out by our diagram of a transverse section of a vertebrate and an invertebrate [**2**].

There is one other structure to which reference must be made in this connection. Between these two tubes, running along the axis of the trunk, is the back-bone—shown in the longitudinal section [**1**]. In the very lowest vertebrates, and in the embryos of higher vertebrates, there is in this position a structure termed the notochord. This is present in *every vertebrate embryo*, and represents the foundation of the spinal column or back-bone.

A Visible Transformation. We may note, further, that in all vertebrates, at some stage of their development, are some openings or slits at the side of the throat, forming a passage from the exterior to the pharynx. In terrestrial mammals, reptiles, and birds these slits are present in the embryo only, and are functionless, merely indicating that the ancestors of these creatures once had need of them. *In fish they persist as the gill-slits. In the development of an amphibian, such as the frog, the transformation from the stage possessing* gill-slits like a fish into a terrestrial animal breathing by lungs, can be actually seen.

It is hardly necessary to add that all vertebrates have a blood circulation through tubes, the propelling power being the heart; that the chief part of the nervous system is the brain, which is continuous with the spinal cord, and from both of which the nerves arise; and that the organs of sensation are in reality outgrowths of the brain.

Mammals and Birds. We may now indicate the predominating characteristics of the five great groups of vertebrates, noting only those points which mark them off from each other. The highest of these groups is that of the Quadrupeds, or Mammals, amongst which is man himself. Two striking characters at once call for notice—namely (1), the possession of *hair*, and (2) the presence of *milk glands*, by means of which the young are nourished for a longer or shorter period after birth. These two points are alone sufficient to separate the mammals from other vertebrates. Moreover, with the single exception of the lowly Monotremes of Australasia, all mammals bring forth their young alive, and do not lay eggs. In all mammals, too, the blood is warm; they are what are termed "warm-blooded vertebrates," in contradistinction to the fish and amphibians, in which the blood is cold.



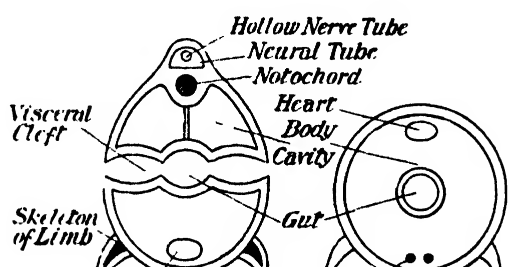
1. LONGITUDINAL SECTION OF VERTEBRATE TRUNK.

S. Spinal cord.
B. Backbone.
T. Thorax.
D. Diaphragm.
A. Abdomen.

Turning from the mammals to the familiar group of Birds, we recognise at once that the outer covering is not hair, but *feathers*, the growth of which largely determines the shape of the bird in nature, as will be realised if a plucked bird is compared with one with the feathers still on. The fore limbs take the form of wings, this being only one of the many adaptations for an aerial life presented by birds. The blood is considerably hotter than that of mammals, being on an average 103°F., compared with about 98°F. in mammals. All birds are egg-layers or oviparous; in no case are the young brought forth alive. "Oviparous vertebrates with a covering of feathers," sums up their characteristic features.

Reptiles. Both the groups just described — mammals and birds — have been termed warm or hot-blooded, which means that they possess not merely warm blood, but blood whose temperature is maintained at a fairly constant level, irrespective of external conditions. Associated with this state of the blood is the necessity of elaborate arrangements for breathing, and along with this warm blood is found the greatest physical activity and the highest degree of intelligence. In striking contrast with these two high vertebrate groups are the Reptiles, in which the blood is cold—that is to say, the temperature of reptile blood is approximately that of the surrounding medium, whether that be air or water. It is, therefore, warmer in hot weather than in cold. Broadly speaking, the result of this is sluggishness of movement and a low degree of intelligence. The external covering is entirely different from that of either mammals or birds. It usually takes the form of hard horny scales, as in snakes and lizards, whilst in some forms, as the turtles, large portions of the skin are ossified into plates. The breathing apparatus, as might be expected from the cold condition of the blood, is much simpler than in birds or mammals, and the reptile breathes by its lungs alone throughout life. Most reptiles are egg-layers, but some carry the young until fully developed, when they rupture the egg-membrane and are born ovo-viviparously.

Amphibians and Fish. The fourth group of vertebrates—the Amphibians—are often confused in the popular mind with the reptiles, but they are more nearly related to fish, as the reptiles are closer allies of birds. The important points of distinction are, therefore, those in which they differ from fish. In Amphibians, such as frogs, toads, and salamanders, true lungs are always present in the adults, while in the early stage of growth there are filaments which are adapted for breathing the air dissolved in the water in which the young amphibian is developing. Moreover, the limbs of amphibians are never converted into fins, and the external covering is soft, moist, and glandular, unlike that of either reptiles or fish. There are other minor points of difference which need not be noted here. Unlike mammals and birds, but in common with reptiles and fish, the blood of amphibians is cold.



2 CROSS-SECTIONS THROUGH A VERTEBRATE (A) AND A HIGHER INVERTEBRATE (B).

Lastly, among the true vertebrates, we have the Fish, which are always provided with gills throughout the whole of life. The blood is cold, and the limbs, when present, are but imperfectly developed, taking the form of broad expansions of the skin, called fins. The body is usually coated with a covering of scales. The shape of the body is adapted for rapid progression through the water, so that there is no obvious line between the head and the body, or the body and the tail.

It will be convenient for reference if the main points in these five groups be summarised in a table.

SOME DISTINGUISHING VERTEBRATE CHARACTERS.

Group.	External Covering.	Blood.	Breathing.
Mammals .	Hair	Warm	Lungs.
Birds . . .	Feathers. . . .	Hot	Lungs.
Reptiles . .	Scales or Plates	Cold	Lungs.
Amphibians	Soft and moist.	Cold	Gills first, then Lungs
Fish . . .	Scales	Cold	Gills alone

The Vertebrate Border Line. There has been no difficulty so far in selecting points of likeness and difference between animals which enable us to put them into certain well-defined groups. But when we leave the true vertebrates, or animals with back-bones, we come to creatures which seem to be on the Vertebrate Border Line. Until comparatively recent times they were regarded as Invertebrates, because in them there was not a true back-bone. But, as was pointed out when describing the essentials of a Vertebrate, this structure is preceded by what is termed the notochord, the firm rod which runs longitudinally below the spinal cord. It was also stated that vertebrate embryos exhibit at one stage the presence of slits in the pharynx; and, thirdly, that typical Vertebrates possessed a nervous system above the notochord, which was in the form of a tube. Now, if these three great characters be taken as the test, it is found that certain very primitive forms have some claims to rank as vertebrates One of these is the small fish-like creature known as a *Lancelet;* another is the curious *Sea-squirt;* and there is a third group represented by a worm-like animal, called *Balanoglossus.*

In the case of the Lancelet, there is a well-developed notochord present; no gill-slits are to be seen outside, but are found on dissection within, and above the notochord there is a tubular nerve cord. So that this curious little creature—it varies from 1½in. to 3in. or so in length—conforms to the three standard tests of a vertebrate. It is, at any rate, on the border line; it is almost a true vertebrate.

The Wonderful Sea-Squirt. In the second form—the Sea-squirt—only one of these three characters is obvious—namely, the perforation of the pharynx for breathing purposes. But if the development be studied, additional evidence is forthcoming in the shape of a notochord in the tail region Moreover, the young sea-squirt possesses a hollow brain and spinal cord. As the creature grows older, after swimming about freely as a sort of tadpole, it changes its mode of life and becomes sedentary, attaching itself to some rock or other object. Then some remarkable changes follow. The tail, with its portion of notochord, gets smaller and smaller and finally vanishes, and the nervous system, which was hollow, is altered into a solid mass, or ganglion. "We have, therefore," says Professor Ainsworth Davis, "the remarkable phenomenon of an animal which, when young, possesses the distinctive vertebrate characters, but loses most of them in the adult condition, becoming, so to speak, of lower grade. This is a good example of biological degeneration." It shows, also, that it is necessary to study the whole life-history of an animal before it can be thoroughly understood.

The third form which we have referred to as on the vertebrate border-line is a worm-like creature without a popular name, technically called Balanoglossus, found widely distributed in the world, dwelling in mud or sand. Gill-slits are found on the upper side of the trunk, a small notochord projects into the proboscis, and what represents the nervous system in this creature is a more or less hollow tube in the region of the collar. So that here again is the indication of the vertebrate border-line.

Creatures without Backbones. We have now sketched in outline the chief features of the Vertebrate animals, and it remains to indicate some of the features of the remaining mass of animals, all of which come under the general heading of Invertebrates.

This enormous collection of creatures without back-bones is divided into a great number of separate groups, each group on the same footing as the Vertebrates. These many divisions are matters for the systematic zoologist; all that is required here is to draw attention to the great diversity of form included in the Invertebrate group. They differ among themselves far more widely than do the vertebrate sections; indeed, there is very little in common between one of the lowly invertebrates and one of the higher, except the common absence of anything in the shape of a back-bone.

Let us take in imagination one of the higher invertebrate forms—a lobster, for example—and look at the great distinctions between such a creature and one of the lower vertebrates, such as a fish. A careful analysis will establish the presence of the following characters:

1. A protective hard external covering, but no internal skeleton corresponding to a skull or back-bone.

2. The body is composed of a single tube, not a double one.

3. The sides of the pharynx are not perforated by gill-slits.

4. The central part of the circulation, the heart, is dorsal instead of ventral as in a vertebrate.

5. The nervous system is composed of a ring round the gullet, continued backwards as a ventral nerve-cord.

We have already said that this great division of the animal world, the Invertebrates, includes a number of widely-differing groups, some of which are small in the number of their species, while others include myriads of creatures. They will be found dealt with in another part of this work [see NATURAL HISTORY].

To be continued

A SHORT DICTIONARY OF TERMS IN BIOLOGY

ABDOMEN—In vertebrates, the hinder part of the trunk, containing the principal organs of digestion and excretion.
Abiogenesis—Spontaneous generation, or the production of living beings without pre-existent life.
Accretion—The process by which inorganic bodies grow larger.
Adaptation—The adjustment of animals or plants to surroundings.
Albinism—Whiteness or paleness.
Albumen—The complex substance of which the white of egg is composed
Ambergris—A concretion formed in the intestine of the sperm-whale.
Amœba—A unicellular animal which changes its shape.
Amœboid—Like an amœba, changing in form.
Amphibia—One of the five Classes of vertebrates.
Anabolism—The chemical processes which build up the tissues
Analogous—Having the same function.
Anatomy—The study of structure.
Antenna—A feeler of an insect.
Anterior—Towards the front of the body.
Anthropoid—Man-like.
Aorta—The great artery of the body.
Artificial selection—The production of breeds by human agency.
Asexual—Reproduction in which sexes are not concerned.
Atlas—The name of the first vertebra in the neck.
Auricle—One of the cavities of the heart.
Aves—The class of Birds.
Axis—The second vertebra of the neck.

BILATERAL symmetry—Having right and left sides alike
Biology—The science of Life and living things.
Blubber—A thick layer of fat under the skin.
Body cavity—The space within the body-wall.
Brachial—Pertaining to the arms.
Branchial—Pertaining to the gills.
Bronchus—A branch of the wind-pipe.
Bud—An outgrowth which becomes an individual animal.

CALCAREOUS—Pertaining to lime.
Canine—Dog-like, applied to certain teeth.
Carnivorous—Flesh-eating.
Carpus—The wrist, the small bones between the forearm and hand.
Cartilage—Gristle.
Caudal—Pertaining to the tail.
Cell—The unit of structure, a nucleated mass of protoplasm.
Cephalic—Pertaining to the head.
Cerebellum—The small or hinder brain.
Cerebral hemispheres—The highest part of the vertebrate brain.
Cervical—Pertaining to the neck.
Chlorophyll—Green colouring matter of plants.
Choroid—The pigmented middle coat of the eye.
Cilia—Hair-like minute filaments projecting from the surface.
Ciliary action—The movement of cilia.
Clavicle—The collar-bone.
Cloaca—The cavity into which the excretory organs open, as in a frog.
Commensalism—The association of two organisms to the advantage of one or both.
Conjugation—The fusion of two individuals for reproductive purposes.
Crop—A part of the gullet for temporary food-storing.
Cross-fertilisation—Fertilisation of an egg by a sperm from another organism.
Cross-pollination—Transferring pollen from the stamen of one flower to the stigma of another.
Cytode—A simple portion of protoplasm without a nucleus.

DEGENERATION—The process by which organisms become parasites or fixed.
Development—A series of changes in the early life of an animal during which it passes from the state of a single fertilised cell to the adult condition.
Digitigrade—Walking upon the digits.
Distal—The end of a limb or extremity furthest from the trunk.
Dorsal—Pertaining to the region of the back.

ECTODERM—Outer cellular layer of the organism.
Embryo—The young animal during development within the egg or womb.
Embryology—Science of development
Endoderm—The inner cellular layer of an organism.
Endoskeleton—Internal hard supporting structures, as bones.
Epigenesis—Gradual development from the simple to the complex.
Exoskeleton—External hard supporting structures.

FEMUR—The thigh-bone.
Fertilisation—The fusion of two masses of germ-plasm
Fission—Reproduction by splitting of the parent cell.
Fossils—The remains of organisms or their traces in rock.

GAMETE—An unfertilised germ cell.
Gemmation—Reproduction by budding.
Genus—A group including one or more species.
Gill—An organ for breathing the air contained in water
Gizzard—A part of the digestive tube in which food is broken up.

HERBIVOROUS—Eating plants.
Hermaphrodite—Having the two sexes united in one individual.
Hibernation—Passing into a torpid condition, as in reptiles
Histology—Science of minute structure.
Homologous—Having a similar origin; constructed on a similar plan.
Host—The organism which carries a parasite.
Hybrid—An individual produced by crossing two species.

IMAGO—The adult stage of insects.
Incisor—The front tooth in mammals.
Invertebrate—Without a backbone.

LABIUM—The lower lip, in insects.
Labrum—The upper lip.
Larva—A young animal which has left the egg and is free, but incompletely developed.

MACRONUCLEUS—The large nucleus in some organisms.
Melanism—Unusual darkness of colour.
Mesoderm—The middle cellular layer of organisms.
Metabolism—Chemical change in body.
Metamorphosis—The period in the life of some insects during which the change occurs from the larva to the imago.
Metazoa—Many celled animals.
Micronucleus—The small nucleus in some organisms.
Mimicry—Resemblance between species, often for protection.
Morphology—Science of structure.

NATURAL selection—The survival of individuals which possess advantageous variations.
Neural—Pertaining to the nervous system.
Notochord—A supporting rod under the central nervous system in all vertebrate embryos, usually replaced later by the backbone.
Nucleus—The specialised portion of protoplasm within a cell.

OCCIPITAL—Pertaining to the back of the head.
Omnivorous—Having a mixed diet.
Ontogeny—Individual development.
Ovary—The female sexual gland.
Oviduct—The tube from the ovary to the exterior.
Oviparous—Producing eggs, or producing young from eggs.
Ovoviviparous—Producing young from eggs hatched within the body.
Ovum—The female sexual cell, the egg.

PARASITE—An organism which lives on or in another.
Parthenogenesis—Production of new individuals from unfertilised eggs, and therefore without the male element.
Pentadactyle—Having five digits
Permanent dentition—The second set of mammalian teeth
Phylogeny—The evolutionary history of animals.
Phylum—A large division of the animal kingdom, *e.g.* Vertebrates.
Plantigrade—Walking upon the palms of the hands or soles of the feet.
Protoplasm—Physical basis of organised tissues; simplest form of living matter.
Protozoa—Lowest division of the animal kingdom.
Pupa—A stage in insect life.

REGENERATION—The process of repair after injury.
Reversion—The appearance of traits like those of remote ancestors.

SEGMENTATION—Early divisions of an egg after fertilisation; also the division of an individual into rings or segments.
Self-fertilisation—Fertilisation of an egg by a sperm from the same individual.
Self-pollination—Transference of pollen from stamens to stigma of the same flower.
Soma—The body as distinct from the germ cells.
Somatic—Pertaining to the body as opposed to the germ cell.
Special creation—The belief that species were created independently.
Spermatozoon—The male sexual cell.
Spinal cord—The hinder part of the central nervous system.
Stigma—An air tube in insects. The pollen-receiving organ in plants.

VACUOLE—A space in the protoplasm of a cell.
Variation—The appearance of new traits.
Vegetative propagation—Reproduction by other methods than egg-production, *e.g.* budding or fission.
Ventral—Pertaining to the lower aspect of the body.
Vestigial—Pertaining to an organ which has undergone reduction.
Visceral clefts—The slit-like openings on each side of the throat which every vertebrate embryo exhibits.
Viscera—Organs within a body-cavity.
Viviparous—Producing young alive.

WARNING colouration—Conspicuous colouring of organisms which have dangerous or unpleasant traits.

ZOOGEOGRAPHY—The distribution of animals on the earth.
Zoology—The science of animals.
Zygote—A fertilised germ-cell

CONDUCTED BY

J. CUTHBERT HADDEN, Musician and Littérateur; Member of the Tonic Sol-fa College; fifteen years Organist of St. John's Parish Church, Edinburgh.

Professor SOLOMON, Professor of Music at the Royal Academy of Music, London; Principal Trumpet in London Symphony Orchestra, and at Worcester, Gloucester, and other festivals.

ALGERNON S. ROSE, Founder Westminster Orchestral Society; Fellow Philharmonic Society.

MARY WILSON, Professor of Singing at the Croydon Conservatoire of Music; Sub-Professor of Singing at the Royal Academy of Music.

Mrs. KENNEDY-FRASER, Lecturer on Music, and author of Musical Works.

PAUL CORDER, Associate of the Royal Academy of Music and holder of the Goring Thomas Scholarship 1901-4.

A FIRST LESSON IN THE THEORY OF MUSIC

By J. Cuthbert Hadden

EVERYBODY knows a musical sound when he hears it. How is such a sound produced? "By vibrations or movements excited in the air which surrounds us," says the man of science. These vibrations may be set in motion in various ways—by the human voice in singing, by the agitation of a string, by the forcing of a column of air through a tube—as in wind instruments—by the striking of a sonorous substance. If the resulting vibrations are very slow, the ear receives no impression of them; if they are broken and irregular, the product is not music but noise.

Musical sounds are, therefore, to put it in a word, the result of rapid and regular vibrations of the air. Such sounds may be high or they may be low. When they are high, the vibrations producing them are very rapid; when they are low, the vibrations are proportionately slow.

Two Main Essentials. Thus we have musical sounds as they strike on the ear. How are we to represent them on paper, so that they may be produced by voice or instrument at will? This is the subject of our present study—the notation of music. In providing a written "language" for music, two main essentials have to be considered: (1) the pitch—that is, the acuteness or the gravity—of sounds; (2) the length or duration of these sounds.

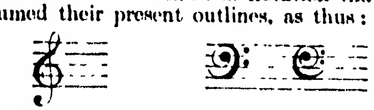
To determine the pitch, a series of lines and spaces called the *Staff* or *Stave* is used, with the addition of "Clef" signs, to be explained presently. Looking at a single "part" in any musical composition, it will be found that it is set down upon a Stave of five lines; but in theory the Stave must be regarded as a great ladder of eleven lines and ten spaces, broken up into two divisions merely for convenience of "reading." Vocal music was naturally the first consideration of those who devised a notation; for voices are old as creation, while instruments were a later evolution. A man's voice is lower than a woman's: he sings from the lower part of the Stave; the woman sings from the upper part. Hence it came about that the Great Stave of eleven lines and ten spaces was split up into halves. With eleven lines it could not be equal halves, of course, so the middle line was omitted, to be introduced as a short line only when required. The final result was therefore like this:

The original Great Stave should, nevertheless, form the basis of the student's theoretical knowledge. These lines and spaces are counted from the bottom upwards. Musical sounds are named after the first seven letters of the alphabet, and the stave lines represent, in their order, the

sounds G, B, D, F, A, C, E, G, B, D, F, while the spaces represent A, C, E, G, B, D, F, A, C, E.

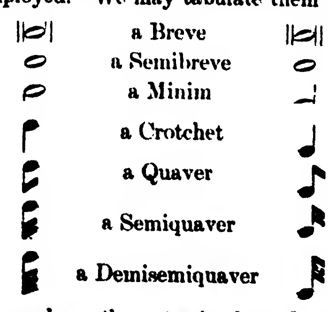
The student is strongly advised to learn these names by heart before proceeding. He must not be content until he can give at once, without hesitation, the name of any line or space within the entire range of the Great Stave. For those who are looking forward to playing an instrument this is especially essential. The singer may grope his way about, guided by a possibly good ear, but the instrumentalist must *read* his notation.

Clefs. Having cut up the Great Stave into two little staves, as it were, the question came to be how to indicate which part, the upper or the lower, was in use. It was with this object that the now familiar *Clefs* were introduced. "Clef" is the French word for *Key*, and these clefs are the keys by which the respective halves of the Great Stave are determined. In old music several clefs were used, and several clefs are still used in full scores; that is to say, in written orchestral music. In all ordinary modern music, however, only two clefs are found. They are known commonly as the Treble and Bass Clefs; more correctly as the G and F Clefs. The names in the latter case are derived from the position assigned to the respective clefs, the one turning on the G line of the Treble Stave, the other having its centre on the F line of the Bass Stave. As a matter of fact, these clefs were originally written in the form of the letters G and F; and it was not until far on in the evolution of musical notation that they assumed their present outlines, as thus:

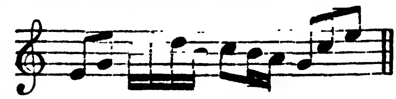


Treble Clef. Bass Clef.

Notation. The supporting fabric of written music being thus provided, we have to consider what to place upon it. This brings us to the question of notation proper—the symbols by which the pitch and duration of musical sounds are represented. If pitch alone had to be determined, one character would serve the purpose. But musical sounds may be of various lengths, as well as of different pitch, and to distinguish these lengths seven forms of note are employed. We may tabulate them thus:

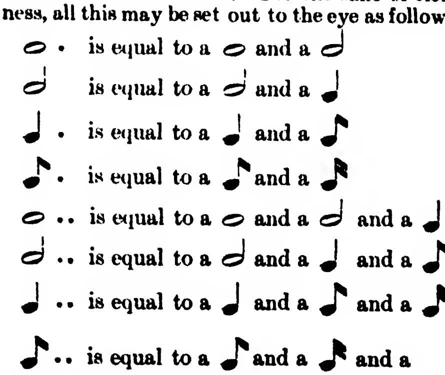


Here we have the notes in the order of their time value, each note being twice the length of the one which succeeds it; so that if, for example, you count four for a semibreve, you will count two for a minim, one for a crotchet, and so on proportionately. Observe that the tails of the notes may be turned up or down at pleasure. In the case of "tailed" notes with hooks, the hooks are often drawn together when two or more such notes appear consecutively, thus:



This "tying" of tails in no way affects the time value of the notes; in many cases it is done just because the notes look better when written in that way. With regard to the breve, the first note shown in the above table, this will be found, as a rule, only in Church music. In very old music notes of even greater length were used, but these are now discarded. In the matter of time, modern music may be said to begin with the semibreve.

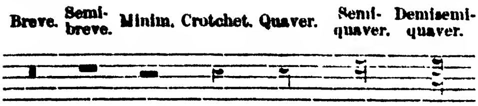
Time Values. Now look at the notes again. The semibreve, let us say, will last while we count four. Suppose we want it to last while we count six? There are two ways in which this may be indicated in writing. We may "tie" a minim to the semibreve, or we may add a dot. The latter is the more usual way of increasing the length of a note. The formula of the theory books is this: A dot after a note adds to the note one-half of its own time value. Thus, a dotted semibreve is equal to a semibreve and a minim; a dotted minim to a minim and a crotchet; a dotted crotchet to a crotchet and a quaver; and so on. Sometimes a second dot is required, when the time-value of the note is increased by three-quarters of its own length. Stated in another way, the second dot takes half the value of the first dot. For the sake of clearness, all this may be set out to the eye as follows:



A third dot, having half the value of the second dot, is used rarely.

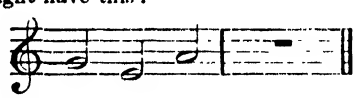
Rests. So much for the relative duration of notes. What if we want an absolute silence now and again? How is the silence to be indicated? This brings us to the question of *Rests*. Every note—semibreve, minim, crotchet, etc.—has its corresponding rest, whose time-value is exactly that of the note which it repre-

sents. Here are the forms of these different rests:

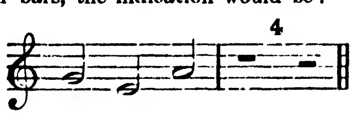


The student will find a little difficulty in readily distinguishing the semibreve from the minim rest and the crotchet from the quaver rest. Let him try to remember that the semibreve rest hangs from the line, while the minim rest sits on the line; that the head of the crotchet rest is turned to the right, whereas that of the quaver rest is turned to the left. On the Continent they have a more distinctly-figured quaver rest, written thus 𝄽, which is occasionally introduced in English music.

In ordinary usage rests are no trouble to the reader of music who knows the notes for which they stand and the time-value of these notes. The respective rests are simply the equivalent silences of equivalent sounds. But there are one or two unusual usages connected with them, of which the student must make careful note. For example, the semibreve rest is employed to indicate silence for a whole measure or bar (bars will be explained further on), no matter what the length of the measure may be. Thus we might have this:

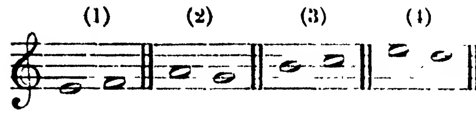


Here the semibreve itself would have represented the time of only two minims, whereas its rest is made to represent the time of three minims. On the other hand, silence for several bars is generally indicated by the appropriate rests, with the number of bars written in a plain numeral above the Stave. Thus, if the single bar rest of the last example were to be extended to four bars, the indication would be:



Other occasional peculiar usages find, as a rule, an easy explanation in the context. Rests, of course, may have dots placed after them to lengthen their time-value, just as in the case of the notes they represent. In practice, however, rests are much less frequently "dotted" than notes.

Scales. We have seen how the musical sounds represented by the first seven letters of the alphabet are represented on the Stave. Now we have to consider how these seven sounds may be modified. We shall speak of scales again in more detail. Meantime, let us run up the scale which begins on the note C. If the student has a pianoforte or a similar keyed instrument at hand, he should refer to it. He will find that only between the keys E and F, and B and C, is there no other key—no "black" key. This illustrates and emphasises the fact that the notes written on adjacent lines and spaces of the stave are not all equi-distant in the matter of sound. Look at this:



If you play (1) and (3) on the pianoforte, you will find that in both cases there is no note between; while, if you play (2) and (4), there *is* a note between.

Well, this intermediate note represents that modification of the foundation notes of the musical alphabet of which we have spoken. Between E and F, and B and C, the pianist (say) cannot place any other note: the distance, technically termed a semitone, is too small to be disturbed. All the other steps of the musical alphabet (C–D, D–E, F–G, G–A, A–B) represent a whole tone; consequently we can throw in a half-tone between each two. The question now is, how are we to indicate this modification, these extra notes, in our written notation?

Sharps and Flats. This introduces us to the *Sharp*, *Flat* and *Natural*, which are written in this way:

Sharp ♯. Flat ♭. Natural ♮.

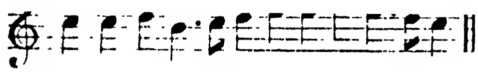
The names are almost self-explanatory. The sharp raises the pitch of a note a semitone; the flat lowers a note, also a semitone. The natural, again, restores a note which has been sharpened or flattened to its original pitch. Double sharps (written thus: X) are often employed, raising a note two semitones; double flats (♭♭), seen less frequently, lower a note also two semitones. It is unnecessary to illustrate in notation the use of sharp and flat. Observe, however, that either of these inflecting signs applied to a note affects any repetition of that note in the same bar or measure. Thus if we write:

the second G will be "sharp" like the first. In order to have it otherwise, we must introduce the natural, thus:

Another usage of the sharp and flat is more confusing. When the last note in a bar has been affected by either of these signs and the following bar begins with the same note, the inflecting sign continues in force. Careful musical writers, however, generally repeat the sign in the new bar to avoid misconception. In the case of double-sharpened and double-flattened notes, it often happens that a restoration to the single-sharpened or single-flattened

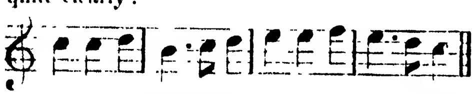
note is required. Here the indication is made by the use of the natural, as thus—♮♯; ♮♭. When certain notes are to be permanently sharpened or flattened—that is to say, throughout a composition, or part of a composition—the requisite sharps or flats are written at the beginning once for all. This results in what is called the *key-signature,* which will be explained more fully later on.

Bars. Reference has already been made to measures or bars. A musical composition is cut up into short sections of equal value, just as a footrule is divided into inches and half-inches. Without this, music would be almost meaningless to the eye, and, in its rendering, supposing it could be rendered, altogether unsatisfactory to the ear. For in music which is to give any pleasure at all, one very essential feature must be present—the regular recurrence of strong and weak accents or beats. Here are the first two lines of "God save the King" without "barring":



Supposing a vocalist, totally unacquainted with this melody, were to try to sing it from the above example. How is he to know that he must put the accent on the 1st, 4th, 7th, and 10th notes? Supposing he were to place the accent on any but the right notes, how it would distort the familiar air! We should not recognise it, in fact.

Here, then, is the object of having music dealt out in bar lengths: it enables us to fix the place of the strong accent, which always follows the bar-line. Thus, the two lines of "God save the King," when barred, come out quite clearly:



In ordinary phraseology the portion of music between two bar-lines is called a *Bar;* less frequently it is called a *Measure,* which is nevertheless the more correct designation. Two-bar lines, termed a *Double Bar,* are used to mark the close of a composition or an important section thereof.

Beats. Just as a composition is divided into bars, so the bars themselves are divided into equal portions called *Beats.* The beats are, as regards accent, strong, medium, or weak. There are different ways of arranging these accents, and according to the particular arrangement so is the nature of the "Time." Writers on musical theory are not uniform in their designations of certain subdivisions of time, but for all practical purposes the terms "Duple," "Triple," and "Quadruple" are sufficient. They are, moreover, preferable to other terms (such as "Common Time"), because they explain themselves. Thus Duple Time has two beats in the bar, the first strong, the second weak; Triple Time has three beats, in the order strong, weak, weak; and Quadruple Time has four beats, strong, weak, medium, weak. In all kinds of time the strong beat is at the beginning of the bar.

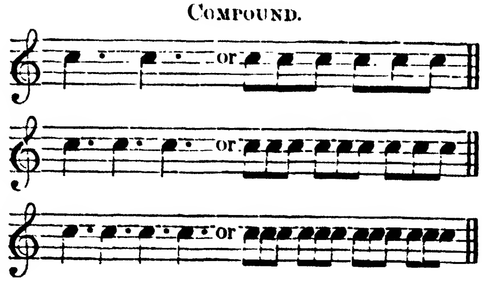
The student will understand that whether music is written in duple, triple, or quadruple time, either minims, crotchets, or quavers can be taken to represent the beat. Thus a bar of triple time may be written in each of the following forms:

It does not follow that there must be exactly 3 minims, 3 crotchets, 3 quavers in every bar of triple time; but there must be the equivalent either in notes or rests. The chief point to notice just now is, however, this—that when the beat is represented by minim, crotchet, or quaver, the time is called "Simple." A qualifying adjective is thus added to the three terms Duple, Triple and Quadruple.

Further, a "Simple" Time obviously implies a time that is not "simple." Hence we get the technical term "Compound." Briefly, the time is "Compound" when the beats are of the value of dotted notes. We may put it all another way, and say that Simple Duple Time applies to measures of 2 beats; Simple Triple to measures of 3 beats; and Simple Quadruple to measures of 4 beats. Compound Duple Time has 6 beats in the measure; Compound Triple Time 9 beats; and Compound Quadruple Time 12 beats. The difference may be readily represented to the eye:

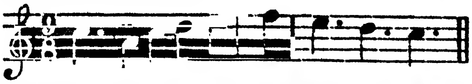
SIMPLE.

COMPOUND.



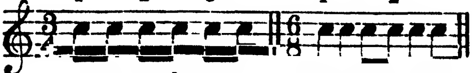
Compound time is generally written in quaver time; that is, the under figure of the signature (to be explained shortly) is usually 8, as $\frac{6}{8}$, $\frac{9}{8}$, $\frac{12}{8}$. It can thus be readily recognised by the grouping

of the quavers into threes, or by the prevalence of dotted crotchets:



Here are two measures containing the same value in quavers, wherein we can only decide the time by the *grouping* of the notes:

1 2 3 1 2



3 accented notes. 2 accented notes.

But the reader of music is not required to examine the measures themselves in order to determine the kind of time. At the beginning of every piece of music he finds a sign called a *Time-signature*. These time-signatures, consisting of an upper figure and a lower, are based on the semibreve as the standard of measurement, and to that note their figures bear direct reference. Thus the signature $\frac{2}{4}$ indicates two-fourths of a semibreve, that is, two crotchets (or their equivalents) in a bar. In like manner $\frac{3}{8}$ means three-eighths of a semibreve (three quavers). In all Simple Time signatures the number of beats in the bar is expressed by the upper figure, which therefore never exceeds 4. Unfortunately, the Compound Time signatures do not so clearly express the number and value of the beats. In this case the figures indicate the notes obtained by dividing each of the beats in a bar into three equal parts. Thus Compound Duple Time would be expressed by $\frac{6}{8}$; that is, six quavers. In all Compound Time signatures the number of notes obtained by dividing each beat into three equal parts is indicated by the upper figure, which therefore is never less than 6.

Time Signatures. It will be best to give a complete table of Time Signatures for reference in case of doubt.

	SIMPLE TIME.		COMPOUND TIME.	
DUPLE (2 beats in the bar).	𝄵 or $\frac{2}{2}$	2 minims	$\frac{6}{4}$	2 dotted minims
	$\frac{2}{4}$	2 crotchets	$\frac{6}{8}$	2 dotted crotchets
	$\frac{2}{8}$	2 quavers	$\frac{6}{16}$	2 dotted quavers
TRIPLE (3 beats in the bar).	$\frac{3}{2}$	3 minims	$\frac{9}{4}$	3 dotted minims
	$\frac{3}{4}$	3 crotchets	$\frac{9}{8}$	3 dotted crotchets
	$\frac{3}{8}$	3 quavers	$\frac{9}{16}$	3 dotted quavers
QUADRUPLE (4 beats in the bar).	𝄵 or $\frac{4}{2}$	4 minims	$\frac{12}{4}$	4 dotted minims
	𝄴 or $\frac{4}{4}$	4 crotchets	$\frac{12}{8}$	4 dotted crotchets
	$\frac{4}{8}$	4 quavers	$\frac{12}{16}$	4 dotted quavers

Of these eighteen forms, $\frac{2}{8}$, $\frac{9}{4}$, and $\frac{12}{4}$ are very rarely met with.

Having got our musical composition divided into bar lengths, with time- and key-signatures prefixed, we still want to have some indication of the pace and general manner of its performance. As to the pace, that is most accurately indicated by what is known as a metronome mark. A metronome is an ingenious little clockwork machine with a dial and a pendulum, which may be shortened or lengthened at pleasure. There is a regulator on the pendulum, and that regulator, placed opposite the dial figure named by the composer, determines the speed of his music. Thus 𝅗𝅥 60 means 60 swings of the pendulum in a minute, each swing representing one beat of the music; in this case the duration of the minim. The metronome, therefore, mechanically and precisely measures the rate, just as the pedometer measures the walking speed of the pedestrian.

Musical Terms. But it is not always necessary to be so precise in the matter of time. It is enough, as a rule, to indicate the general character of a composition, and this is done by means of certain terms with which the student must familiarise himself. A list of these terms is given at the beginning of this course; here it will be sufficient to name those most commonly used, so that the student may look them up in the Glossary. In alphabetical order they are:

Adagio.	*Largo.*
Allegro.	*Larghetto.*
Allegretto.	*Lento.*
Andante.	*Moderato.*
Andantino.	*Presto.*
Grave.	*Prestissimo.*

The application of most of these terms is extended and modified by certain qualifying words, such as *molto* (very), *non troppo* (not too much); *con moto* (with motion); *assai* (more, extremely); *meno* (less); *piu mosso* (more moved, quicker); etc., etc. Thus *Allegro con moto* means with more than the usual degree of motion; *Allegro non troppo*, quick, but not too quick; *meno allegro*, less fast; and so on. In this connection it is well to notice such terms as *Accelerando* (accelerating the pace); *Ritardando* (retarding); *Ritenuto* (holding back); and *Rallentando* (slackening the pace). When the composer desires that the former strict time be resumed after an *Accelerando* or a *Rallentando*, he writes *A tempo* (in time). It should be pointed out, perhaps, that there is some confusion among theorists about the relative value of the terms *Andante* and *Andantino*. The latter is the diminutive of *Andante*, and ought therefore to mean "less going"; but as a matter of fact it seems to be most frequently used to signify "less slowly" (than *Andante*). In regard, however, to the whole subject of pace and mode of performance, it may be observed in the words of Professor Banister, that good compositions to a large extent "tell their own tale, indicate their own character," and it must be left to the performer's judgment to execute them accordingly.

To be continued

A SHORT DICTIONARY OF TERMS IN MUSIC

ABENDLIED—An evening song.
Accelerando—More and more quickly.
Acciaccatura—A short grace note (see text).
Adagio—Leisurely, deliberately.
Ad Libitum — At the performer's pleasure as to time.
Agitato—In an agitated style.
Alla Breve—The time with two minims in a bar; seldom used in modern music.
Alla Cappella—In the church style.
Alla Marcia—In march style.
Allegretto—Light and cheerful; not so fast as *Allegro*.
Allegro—Lively, briskly; in a gay and merry way.
Allemande—A German dance tune in triple time.
Al Segno—To the sign (see text).
Alt—All notes in the octave above G in top space of treble-clef are said to be *in alt*.
Amore, Con—With tenderness.
Andante — Literally, going, walking; going easily, fluently, moving on.
Andantino—Slower than *Andante*.
Animato—Animated, usually as to speed.
Anthem — A sacred composition for voices, words usually Scriptural.
Appassionato—Impassioned, with feeling.
Appoggiatura—A grace note (see text).
Arpeggio—Notes of a chord played in succession (see text).
Assai—Very, as *Allegro assai*, very quick.
A tempo—In time.
Attacca—Attack; without pausing.
Aubade—A morning song.

BAGATELLE—A trifle; a short easy piece.
Barcarolle—A song or composition in imitation of the Venetian gondoliers.
Ben—Well; as *Ben Marcato*, well marked.
Berceuse—A cradle song, a lullaby.
Bis Twice (see Text).
Bolero—A Spanish dance in triple time.
Bourrée—An old French dance in triple time.

CADENZA—An ornamental passage, often improvised at the close of a composition.
Calando—Literally, falling away; gradually softer and slower.
Canon—A composition in two or more parts in which the parts continually imitate each other.
Cantabile—In a singing, melodious style.
Cantata—A choral composition of several movements, with solos, &c.
Canzonet—A piece, vocal or instrumental, of a flowing character.
Capriccioso—Capriciously, as to time.
Catch—A humorous vocal piece for several voices.
Cavatina—A graceful, simple air.
Coda—Tail; the end.
Con—With. *Con Amore*—With affection, lovingly. *Con Anima*—With soul, in a feeling manner. *Con Brio*—With animation. *Con Fuoco*—With fire. *Con Espressione*—With Expression. *Con Moto*—With movement. *Con Spirito*—With spirit. *Con Sordini* With dampers (piano); *i.e.* without pedal.
Crescendo—Gradually louder.

DA CAPO (D.C.) — From the beginning.
Decrescendo—Gradually softer.
Diminuendo—Decreasing as to tone.
Dolce—Sweetly, gently.
Doloroso—Dolorously, with an expression of pain.
Due Corde—Literally, two strings. The soft pedal (piano) to be released.

ENHARMONIC—Similar in pitch, but differing in name, as G♯ and A♭.
Ensemble—Together; *ensemble* playing, concerted playing.
Espressivo—Expressively.
Etude—A study; an exercise.
Extemporise—To create music on the inspiration of the moment.

FALSETTO—Head or feigned voice as opposed to natural or chest voice.
Fanfare—A trumpet tune; a flourish of trumpets.
Fantasia—A composition in free, fanciful style.
Fine—The end; used after a repeat (see text).
Forte, Fortissimo (*f*, *ff*)—Loud; very loud.
Forza, Con—With force.
Fugue—A composition in which parts do not all begin at once, but, as it were, follow each other successively.

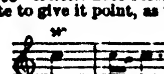
GAMUT—Old term for the scale.
Gavotte—A lively dance of French origin, popular in seventeenth and eighteenth centuries.
Giocoso—Humorously, jocosely.
Gioioso—Joyous, cheerful.
Giusto—Just, strict, as *Tempo Giusto*, in strict time.
Glee—A composition for voices, peculiar to England.
Glissando—The playing of several rapid scale notes successively, by sliding one finger along the white keys of the piano, instead of separately fingering each note.
Gondolied—A gondolier song.
Grandioso—Grandly.
Grave—Gravely, solemnly.
Grazioso, Con grazia—Gracefully.

HORNPIPE—An old English dance.

IMITATION—A species of fugue where the parts imitate each other.
Impetuoso—Impetuously.
Impromptu - Extempore, unpremeditated; a piece like an improvisation.
Intermezzo — Literally, intermediate; introduced between acts of an opera, &c.
Introit—A short anthem preceding the service of the Roman Catholic Church.

LANGSAM—Slowly.
Larghetto—Rather slow, in a broad style.
Largo—Slow and solemn.
Legato—Smooth, connected.
Leggiere—Easily, lightly, delicately.
Lento—Slow.
Lied—German term for a simple song.
L'istesso tempo—The same time; used where a change of time-signature occurs, to indicate that the length of the beat remains the same though represented by a different kind of note.
Loco—The place: after *8va*, to point out that the music is to be rendered in its proper octave, as written.

MA—But; as *Vivace ma non troppo*, lively, but not too much so.
Madrigal—An unaccompanied part song
Maestoso—With majesty or dignity.
Mano Destra (M.D.)—The right hand. *Mano Sinistra* (*M.S.*), the left hand.
Marcato—Marked, emphatic.
Marziale—In martia style.
Mazurka—A Polish dance, in triple time.
Meno—Less, as *Meno allegro*, less lively.
Mezzo—Medium, as *Mezzo forte*, moderately loud.
Minuet—An old French dance, in triple time.
Moderato—Moderate, as to pace.
Molto—Much, very, as *Molto allegro*, very lively.
Mordente—A little note before a principal note to give it point, as thus—



Written. Played.

Morendo — Dying away; gradually diminishing the tone.
Mosso—Moved, as *Più mosso*, more moved, quicker.
Moto—Movement, motion (see *Con moto*).

NOCTURNE—A composition of light and elegant character.
Non—Not; *Non troppo*, not too much.

OBBLIGATO—Indispensable; a part or accompaniment of essential importance.
Octet—A composition for eight instruments or voices.
Op. (for **Opus** or **Opera**)—A work; used to indicate the number of a composition in the order of its composer's works.

PASTORAL—A simple air, in $\frac{6}{8}$ time, of a rustic character.
Ped.—The sustaining, usually called the loud, pedal of the piano.
Perdendosi—Losing in sound, growing softer.
Pesante—Heavily, impressively.
Piano (*p*)—Softly.—**Pianissimo** (*pp*)—Very softly.
Più—More, as *Più allegro*, more lively.
Plainsong—The most ancient kind of ecclesiastical music.
Poco—A little, as *Poco a poco*, little by little.
Polonaise—The Polish national dance, in triple time.
Pomposo—Pompously.
Portamento—Gliding from note to note in singing.
Presto—Fast. **Prestissimo**—Very fast.

QUASI—Like, in the style of, as *Andante quasi allegretto*, Andante in the style of allegretto.
Quintet—A composition in five parts.

RALLENTANDO—Gradually slower.
Recitative—Musical declamation.
Rhapsody—A composition in a free style.
Risoluto—In a resolute manner.
Ritardando, Ritenuto—Retarding the speed.
Rubato—Literally, robbed: *Tempo Rubato*, a slight deviation to give more expression by retarding at one place and quickening at another; not in strict time.

SCHERZANDO—Playfully.
Scherzo—A lively, playful piece.
Sempre—Always, as *Sempre staccato*, always staccato.
Senza—Without.
Senza Sordini—Without dampers (piano), *i.e.* with pedal.
Sforzando, Sforzato (Sf.)—Forced, with great emphasis.
Smorzando—Gradually fading away.
Sostenuto—Sustained.
Sotto Voce—In a subdued tone.
Staccato—Short, detached (see text).
Stringendo—Hurrying on the speed.
Syncopation—Irregular or cross accents; binding the last note of a bar to the first note of the next; accented notes occurring in the unaccented part of a bar (see text: *Counterpoint*).

TARANTELLA—A Neapolitan dance in $\frac{6}{8}$ time.
Tempo—Time. *Tempo Primo*—the original pace (after Rallentando, etc.).
Tenuto (Ten.)—Hold for the full time.
Tremolo—Trembling; the rapid alternation of notes to produce a trembling effect.

UNA CORDA—One string; *i.e.* with the soft pedal.

VELOCE—Rapidly, swiftly.
Vibrato—With much vibration of tone.
Vivace—Lively, vivacious.
Volti Subito (V.S.)—Turn over quickly.

SHOPKEEPING & BUSINESS SYSTEMS

A GUIDE TO THE KEEPING OF SHOPS OF EVERY KIND AND SIZE

WAREHAM SMITH, **Advertising Manager of the "Daily Mail"; and other Authorities.**

THE BUSINESS OF SHOPKEEPING AND ITS BEGINNING

IN this and the subsequent chapters of the series, which, when completed, will form a handy, comprehensive, practical guide to Shop-Keeping, we shall confine ourselves to shops in the sense of "buildings or apartments in which goods, wares, drugs, etc., are sold by retail," and by shop-keeper we mean "Retail Trader, in distinction from a Merchant, or one who sells by wholesale." The shop of the craftsman or mechanic does not come within our scope.

It is astonishing how little may be learnt from books about the all-important subject of Shop-Keeping. It would appear that familiarity with such a common sight as a shop had bred a certain contempt for it.

An Unorganised Community. People have been in the habit from their cradle of frequenting shops, but have never chosen to be interested enough, nor have ever dared to be inquisitive enough, to enquire about the practice and method of shopkeeping. They have always got what they wanted and have cared nothing as to how it was kept. The shopkeeper, too, especially in the past, was invariably of a reserved, exclusive disposition, always too occupied in minding his own business literally to think of putting on record how he carried it on, and thus came to pass the anomaly that, in the literature of the "nation of shopkeepers," no place was found for the subject of keeping shops.

Yet what could be more truly British, and more really important, than the distributive industry of this country. It may be both interesting and useful to note that the exclusiveness just mentioned was only profitable to the shopkeepers individually. It was anything but beneficial to them as a community. It deprived them of adequate political expression, and prevented concerted action being taken for their benefit; such, for instance, as in the regulation of the internal economy of their establishments. For a century or more they were numerous enough to be very powerful, but, without a leader, and having no effective organisation, they were, until quite recently, about the most powerless section of the population, save, perhaps, that still more numerous class the shopkeepers' assistants—the would-be shopkeepers!

False Gentility. But not only did familiarity with shops dull the imagination in respect of shopkeeping, even to the entire exclusion of so important a subject from the literature of the country; it led people to form erroneous notions. The real cause of any falling off in the British distributive industry has been false gentility—the insane notion that there is something derogatory in trade as a career for respectable sons and daughters. Early in the eighteenth century—in the days of Pope—himself the son of a merchant—we know, on the authority of Sir Walter Besant,—that "the tradition of sending the younger sons into trade survived the practice. The younger sons of country gentry no longer sought apprenticeship and fortune in London.... It was considered beneath the dignity of a gentleman to sell anything, or to soil his fingers with any kind of trade, or to deal in any kind of commercial enterprise."

The earliest fortunes that were made in shopkeeping were taken out of the trade and invested in land, upon which the retired tradesmen lived. At first there were their sons and nephews to fill up the gaps in the business, which, despite changes, continued to prosper. By the time the eighteenth century was reached the number of shops had increased enormously, numerous openings were created, and it became necessary to recruit young men to fill these from somewhere.

The Decline in Shopkeeping. No more sons of country gentry were available, while the supply of the sons and nephews of the fortunate retired shopkeepers had become exhausted. Then it was that "the poor youths —those who had everything to gain, and who were already employed in some capacity in the

City—understood what was wanted. There were thousands of such young men; but there were but a few—there are never more than a few—who understood the first essentials of success—how to see and how to seize the opportunity." That these men were uneducated and vulgar we should expect, and a book published in 1800, giving the parentage and history of the City Fathers of that time, abundantly proves it.

If that could be the case two hundred years ago, in the early history of shops, how much more so has it become since! For, during the past 60 years, the number of shops has increased more than it had done during the preceding 500 years. It is obvious, therefore, that the "science and art" of shopkeeping had not advanced in anything like the same proportion to the number of shopkeepers, solely because the trade had not attracted the best educated, the ablest and the noblest of the young men of the country. So that another extraordinary anomaly now existed: this typically British and quite indispensable industry was left almost entirely to those young men who had the least educational and social advantages.

Its Failure to attract. History, then, teaches that trade, as far as shopkeeping is concerned, has suffered, not so much from defective education as from failure to enlist the services of the educated.

Granted, however, that the trade has been carried on by shopkeepers of humble origin, of little or no education, the fact proves only that a better class of men would trade in a better way. Shopkeeping, in these days of acute competition, when the "multiple" shop vies with the limited liability company in squeezing the "small man" out of the field, requires the very best of the youth and manhood of the nation.

Shopkeeping is an indispensable trade that constantly grows in importance, and it offers, therefore, an excellent and lucrative career to capable men and women. There are urgently wanted—to quote Mr. F. F. Bridgewater—"live young men of ideas, who can think for themselves; we must stop sending the best of them to work like machines from ten to four . . . in Banks and Insurance Offices where they have no hope of becoming their own masters. If they earn 30s. a week, at least they can wear a top hat and black coat and call themselves professional men. The banks and insurance companies make a vast profit from this state of affairs. In effect, the bank and insurance clerk pays £2 or £3 a week out of his pocket for his pseudo-professional standing. . . . When we cease to decry the trade which butters our bread, when we have a middle-class which is less steeped in out-of-date conventionality, then we shall find Great Britain doing much better in the commercial warfare which is her lot."

Facilities for Acquiring Knowledge. Shopkeeping, it will thus be seen, affords an excellent scope for healthy young men and young women of energy, education and a fair share of sound common sense, and the problem, therefore, is how to induce the well-educated and good-mannered young men and maidens to adopt shopkeeping as a career.

One important step to this desirable end is the recent welcome activity in the direction of providing facilities for those who are already engaged in trade to acquire the technical education, so essential to their own advancement, which they should have received before entering business. To acquire the knowledge of a trade, which is essential to efficient salesmanship and successful shopkeeping, a period of apprenticeship is absolutely necessary, and it is during this time that the learner is most likely to appreciate the value of technical instruction, inasmuch as he would then be in a position to apply the theories in his daily work, and thus enhance his enjoyment in the performance of his duties.

There are at present very few branches of shopkeeping without a trade organ, and no enterprising shopkeeper can afford to do without the trade paper, which keeps him informed of the state of the market, and of what transpires in the trade outside his own establishment. The Drapery and Grocery trades are particularly well catered for; the Ironmongery, Hardware, Boot and Shoe Leather, Chemists and Druggists, Fruiterers, and Tailoring trades are also well supported.

An Excellent Field for Investment. It is also, with efficient management, an excellent field for investment. The "small man," the widow, and other peculiarly situated people who are possessed of a limited capital may confidently turn their attention to shopkeeping on a small scale if they use judgment in their selection of locality and study the needs of the population. The greatest care must be exercised, in taking the premises, not to yield to exorbitant exactions as to rent and agreement; the employment of a reliable solicitor is desirable in even the most seemingly trifling circumstances, lest there may lurk in some clause an error or omission capable of endless trouble and litigation afterwards. In most businesses on this small scale it should be borne in mind that it is usually the rent that kills. Care should be taken, also, not to start in a new thoroughfare or locality, unless the capital is large enough to ensure against the almost certain loss which must be faced during the first year or so. One has only to consider the number of times a shop in a new Arcade or on a new Terrace usually changes hands before it yields a profit over and above the establishment charges to appreciate the value of this hint.

Essentials for a Good Choice. The choice of a trade mainly depends upon three things—the taste or qualifications of the candidate, the amount of the capital at his disposal, and the needs of the neighbourhood. The man or woman who contemplates the opening of "a little shop" without previous experience is limited in the choice of trade to enter; and while a certain amount of knowledge of any trade is highly desirable before attempting to conduct it, there are a few which may be mastered so easily that no previous

knowledge of them is essential. It is well to study the possibilities from every standpoint when selecting the site, especially if the start be ventured in a new district, in which case everything should be done with a view to the future. Care must be taken to avoid any reckless or unnecessary expenditure to "push the trade" beyond the capacity of the district, which is always a temptation if progress be slow and the returns only moderate.

The Site. The most commanding site available should be selected, so that the most may be made of a good display. Judging by the stale and dusty appearance of the window in most small shops not owned by enterprising capitalists or the companies, window-dressing is sadly neglected, though it be one of the finest arts, requiring all the genius and the skill of the painter and draughtsman combined to practise it in its perfection. No business is so small that it would not profit by having great attention paid to its window-display. From sheer force of habit, involuntarily and almost unconsciously, we look at shop windows and take in the contents at a glance, but only the effectively-dressed or displayed windows compel the closer inspection which usually leads to a purchase. But it is not sufficient nowadays to make an effective display for universal admiration merely, but a free and judicious use of the ticket-writer's art must be made to represent value in a tempting and convincing fashion. The tickets must be neither too big nor yet too full—they must be clean, the letters and figures must be bold and neat, and the articles to which they are affixed must be the perfection of their kind—clean, fresh, and unblemished. The newsagent, the tobacconist, or the fruit shop situated at or near the terminus of a railway or a tramway, or at or near the corner of a busy thoroughfare, or the confectioner with an appetising, wholesome, and inexpensive display of sandwiches, porridge and stewed fruit, near a workshop where many hands are employed, is assured of a flourishing time if he takes care of his window. "Take care of your window and your window will take care of your shop," may well be accepted as the motto of shopkeeping.

Good Management. Having chosen the line of business and settled the important matter of locality and premises, all is plain sailing if due care and cautiousness, judiciously directed energy, and the liberal exercise of common sense are given free play. However small the concern may be, too much care cannot be given to the matter of keeping an account of every payment made and of the takings every day; and the smaller the business the more imperative it is to insist upon cash for every purchase, never yielding to the habitual temptation to give credit, however small.

No elaborate system of book-keeping is needed. Two books at most are ample—a day-book and a cash-book. The shop and everything in it should at all times be scrupulously clean, and the habit of pleasing the customers from the first should be assiduously cultivated No business can succeed without advertisement, and no advertisement is so effective as the treating of customers in such a way as to cause them to repeat, and to continue to repeat, their custom. And all the main essentials to this end are the free gifts of Nature. It is incumbent on all shopkeepers to be careful that such talents as they have shall not be hid. Without them, salesmanship is well-nigh impossible, and efficient salesmanship is the concentrated essence of all the qualifications needful in successful shopkeeping. According to one modern authority, "health, sincerity, ability, industry and knowledge" are the five great essentials of good salesmanship. Upon these things depends the success of shopkeeping, whatever the line of business may be.

Kindred Trades. We are concerned with shopkeeping generally, and with such qualifications as are common to all classes of trade. Many trades are kindred to one another. The most comprehensive, probably, is the drapery trade, which includes, besides linen and woollen products, a large variety of other textile goods, such as silks, satins—which are specialised by silk mercers—hosiery, lace, ribbons, haberdashery and fancy goods. The grocer finds it quite convenient to deal in provisions, dairy and garden produce, meat and poultry. The ironmonger naturally supplies oils and colours, hardware and machinery. The stationer is expected to supply books, newspapers and fancy goods, while chemists and druggists frequently encroach upon some of the grocer's specialities. The newsvendor is generally also a confectioner, stationer, tobacconist and toy-dealer. It is fast becoming the rule for the largest drapery establishments to emulate the mammoth stores by including everything saleable, or, at any rate, to provide anything required for furnishing the house, and for clothing as well as feeding, doctoring, and recreating the persons living in it.

Shopkeeping Law. Shopkeepers are expected to acquaint themselves with the provisions of many Acts affecting their trade, notably the Sale of Food and Drugs Acts of 1875, 1879, and 1900; the Margarine Act, 1887; the Merchandise Marks Act, 1887; and the Shop Hours Regulation Act, 1892. The last of these provides that no young person shall be employed "*in or about a shop for a* longer period than 74 hours, including meal-times, in any one week," and imposes a fine not exceeding £1 for every person so employed. Owing to a defect revealed in this Act by the case of Hammond *v.* Pulsford, another Act was passed to remedy it by enacting that a notice is to be exhibited by the employer in a conspicuous place, stating the number of hours in the week during which a young person may be lawfully employed in the shop. Any employer who fails to exhibit this notice may be fined £2.

Among more recent Acts are the Shop Hours Act of 1904, enacting that an order for the early closing of shops may be made by a local authority either throughout the area of the

local authority or in any specified part thereof. The closing of shops on Sundays, however, is left wholly to the operation of the Sunday Observance Act of 1667. The Employment of Children Act, 1903, the Weights and Measures Acts, the Sale of Food and Drugs Acts, and many others, also affect the shopkeeper, and he should not fail to make himself acquainted with their meaning.

Capital to begin with. The question of the amount of capital at disposal is a most important one. As the yearly list of failures only too amply proves, insufficient capital is the most prolific source of insolvency. Whereas a small shop—a newsagency, tobacconist's, stationery, confectionery, or a "little general"—may, with extreme care and economy, be started with any sum from £20 to £100, a shop in the grocery, drapery, ironmongery, or any trade specially allied to these, cannot hope for success if the initial capital is less than £500. There may be a few instances where special ability, with the assistance or indulgence of the wholesale trade, has succeeded in building up a business with a smaller capital, but it is a risky speculation at best when, in counting the cost, a liberal provision is not made for the ready cash for stock-in-trade, and, also, for establishment charges, such as rent, rates, taxes, insurances, labour and incidentals. All these must be regularly met, whether there be a brisk sale or not. It is essential that stock should be promptly paid for, so as to secure the increased discount for cash, however trifling. Nothing could be more instinct with failure for the beginner in shopkeeping than a false start in this respect.

Shop System. Time-saving and labour-saving appliances, while essential to a business of any respectable dimensions, are hardly profitable in the small business, where the trade does not demand their aid and the capital for working purposes is limited. "Necessity is the mother of invention," and inventions are only profitable when the growth of the business necessitates their use. In a huge establishment, the simple, toy-like, but perfectly efficient overhead cash-railway system is invaluable in many ways; it enables the salesman during the few seconds the ball is rolling to and from the desk to introduce another "line," or to attend to other customers. Moreover, the counter and the customers are not left unattended, and the assistants are spared the fatigue of frequent running and dodging about. In a large provision business the bacon-cutting machine and cold storage appliances are indispensable. In establishments where the living-in system is in vogue, large sums are profitably invested in making the culinary department replete with the latest cooking-appliances, such as kitcheners, bread-slicers, and knife-cleaners. Equally indispensable to the efficient conduct of business are all the products of electrical science—the lift, the telephone, the electric-bell, and the indicator.

Enough has been said to show what an enormous scope for talent, energy, and enterprise is offered in a career of shopkeeping. And, whereas no vocation affords so many temptations to dishonesty or sharp practice, the fact is proved by experience that in no walk of life is the old adage that "Honesty is the best policy" more forcibly verified.

To be continued.

THE CHOICE OF A SHOPKEEPING CAREER.

THE following list details briefly the conditions usually prevailing in the chief shopkeeping trades. It has been carefully compiled from authoritative sources, and the figures given are those that seem to be the more usual throughout the United Kingdom. From most shopkeeping trades the system of indenturing apprentices has almost disappeared. The sum recommended as capital is the minimum upon which a start can be made with any prospect of success.

Baker and Confectioner. Regular apprenticeship not general. Lads are engaged at about 6*s.* per week; journeymen bakers earn from 25*s.* to 35*s.*, foremen rising higher. Capital required to start a bakery equipped with machinery, £150 and upwards.

Barbers. In ordinary barbering and hairdressing apprenticeship varies in length from two to seven years. Boys receive about 2*s.* 6*d.* per week to begin; assistants earn from 21*s.* to 32*s.* plus commissions on articles sold. Business may easily be started on £50 capital. [See also HAIRDRESSERS.]

Booksellers. Conditions similar to those for stationers, but double capital required.

Boots and Shoes. Practical apprenticeship five years, and wages 5*s.* to 14*s.*; journeymen earn from 25*s.* to 35*s.* Girls usually engaged as messenger girls at 2*s.* 6*d.* and rise to 20*s.* or 25*s.* per week. Capital required to start, £120.

Butchers. Errand boy engaged at about 5*s.* weekly and left to work his way up. An assistant salesman going the rounds with pony and trap receives 30*s.* to 40*s.*; shop salesman usually a little less. Cash business may be started on £50; credit business on £150 to £200.

Chemists and Druggists. Premiums of £20 to £100 required in apprenticing to high-class chemists in England. Such apprentices live indoors. Ordinary unindentured outdoors. Apprenticeship wages, 4*s.*, 5*s.*, 6*s.*, 7*s.* weekly; four years' apprenticeship is the rule in both cases. Assistants' wages, 20*s.* to 30*s.* per week for unqualified men, and 30*s.* to 50*s.* for qualified assistants. The best positions are as dispensers in public institutions, or as employees of the large drug stores. Capital required to start Pharmacy, £300.

China and Earthenware. Apprenticeship is unusual, message boys or girls beginning respectively at 4*s.* and 2*s.* 6*d.* per week, rising by experience to be selling assistants, and earning anything up to 30*s.*, according to ability. Business may be started on £100.

Drapers. Apprenticeships usually three to four years and wages 6*s*., 7*s*., 8*s*., 9*s*., per week; assistants make 16*s*. to 30*s*. Living-in apprentices receive no wages, but may receive small commissions on sales during the latter half of term. Living-in assistants receive £20 to £30 a year. Female apprentices not common; female assistants receive 8*s*. to 20*s*. a week, or if living in up to £15 per year. Capital required for small drapery business, £200. Capital should be turned over four times a year.

Furniture Dealers. In the practical side, departmentalism has nearly killed the general apprenticeship system. Where apprentices are taken time is usually for five years, beginning at 4*s*. or 5*s*. and rising to 8*s*. or 10*s*. Journeymen workers earn 7*d*. to 11*d*. an hour. Salesmen frequently begin as message boys at 5*s*. a week and work their way up. Assistant salesmen begin at about 20*s*. to 25*s*. a week, and may rise to several hundreds a year in best shops. Trade usually allied to general house furnishing. Modest business may be set up on £100—£200, but present tendency is towards hire-purchase trading, which requires much more capital.

Grocers. The apprenticeship system is becoming less usual, but where it exists it is from three to four years. Wages, 6*s*., 8*s*., 10*s*., 12*s*. Assistants earn from 17*s*. to 28*s*. Capital required, £170 to £200. Stock should be turned over eight times a year.

Hairdressers. As distinct from ordinary barbers, hairdressers serve no apprenticeship, but may receive instruction in one of the hairdressers' schools in London and the provincial cities. Salaries for artists in ladies' hairdressing are usually from two to three guineas a week, plus commission. [See also BARBERS.]

Ironmongers. Apprenticeship usually four years, and wages, 4*s*., 5*s*., 6*s*., 7*s*. Assistants earn 20*s*. to 40*s*. Capital required to start general ironmongery business, £600. Stock should be turned over twice a year.

Jewellers. A premium of £50 to £100 is usually paid when a youth enters as apprentice, the premium being returned in the form of wages during service. Apprenticeship terminates at the ages of 21. A journeyman jeweller earns from 27*s*. to 50*s*. per week. The best working jewellers in London, the seat of the English trade, are foreigners—French, Belgian, Swiss. Capital required to start business with small stock, £500. Good men have stock on consignment from wholesale houses or manufacturers. In the mixed watch-making and jewelling trade of the provinces a seven years apprenticeship is common, wages beginning at 5*s*. and rising to 12*s*.

Milliners. Two years' apprenticeship and no wages paid. A premium of £10 to £20 is often required. Assistants earn from £10 to £30 a year. Capital required to start, £100; more if extended credit is given.

Oil and Colourmen. In the ordinary oil and colour shop apprenticeship is unusual. Boys begin at about 4*s*. or 5*s*., and in about four years are worth 15*s*. a week, rising as high as 26*s*. or 28*s*. The proprietorship of a business may be attempted with £100 capital.

Opticians. One of the few businesses which are not overcrowded, and where a competence is fairly certain to those electing to follow it. Employers prefer technically trained youths instead of apprentices. Instruction in optics is conveyed at Northampton Institute, London. Assistants easily earn 40*s*. to 60*s*. a week, and managers rise as high as £500 a year. A sight-testing optician may begin business on £250—£350 capital, but to embrace the trade in all its branches £1000 is necessary.

Photographers. Apprenticeship prevails, but not common. Usual length four years, beginning at 3*s*. or 4*s*. a week and rising to 10*s*. Assistant operators earn 20*s*. to 50*s*. Business is often attempted with success on a very few pounds, but to equip a studio properly demands £100 to £200.

Pawnbrokers. Apprenticeship practically unknown. Warehouse boys usually live in, and receive, in addition to board and lodging, £6 or £8 a year. Assistants earn 30*s*. a week; managers in first-class establishments from £250 to £300 a year. Many who enter the trade leave it for other vocations. A merchant business is usually incorporated with pawnbroking proper. Capital necessary, £2,000.

Plumbers. Usually serve five years' apprenticeship, beginning at 4*s*. per week and reaching 10*s*. Journeymen earn from 7*d*. to 11*d*. an hour. Capital required £100, to £200.

Painters. Usual apprenticeship five years. Wages, 6*s*., 7*s*., 8*s*., 10*s*., 12*s*. Journeymen painters earn from 25*s*. to 35*s*. Capital required to start as a painter and paperhanger, £60.

Saddlers. Apprenticeship for practical saddler, seven years; wages, 5*s*., rising to 12*s*. Shorter apprenticeships are becoming more common. Journeyman saddler earns from 25*s*. to 35*s*. per week. A small saddlery business may be started on £100 capital. More is often required on account of the long credit frequently prevailing, and the practice of bribing coachmen and grooms to secure and retain wealthy customers is unfortunately common.

Stationers. Usual apprenticeship five years, and wages, 4*s*. 6*d*., 6*s*., 7*s*., 8*s*., 10*s*. Assistants' wages, 18*s*. to 30*s*. Capital required to start, £100 to £200. Stock should be turned over four times a year.

Tailors. Working tailor's apprentice serves five years, earning 4*s*., 5*s*., 6*s*., 7*s*., 8*s*. 6*d*. a week; journeymen tailor earns 30*s*. to 35*s*. a week, but has much idle time. Capital required to start business holding some stock, £80. Shopmen, as distinct from practical tailors, earn 17*s*. to 30*s*. a week.

Watchmakers. Terms of apprenticeship as under Jewellers, but tendency is to reduce the time served. The two trades are usually allied. Technical instruction in horology given at Horological Institute, London, both to attending students and to learners by correspondence. Wages and other particulars as under JEWELLERS.

SHORTHAND AND TYPEWRITING

THE FUNDAMENTAL QUALIFICATIONS IN COUNTLESS SITUATIONS

BEING

SHORTHAND TAUGHT BY SIR ISAAC PITMAN & SONS ON THE TWENTIETH CENTURY PLAN

AND A PRACTICAL COURSE COVERING

TYPEWRITING, WITH THE WORKING AND MANAGEMENT OF ALL THE CHIEF MACHINES

ADVANTAGES OF SHORTHAND AND THE PITMAN SYSTEM

ALTHOUGH the art of shorthand is of considerable antiquity, it has only within recent years come into general use in this country. There is abundant evidence, however, that it stands to-day in the first rank of subjects of general utility, and its students and practitioners are numbered in millions.

This great development in the use of the art followed, as all the world knows, from the labours of Sir Isaac Pitman in the invention and perfection of the system associated with his name, and from his lifelong efforts in popularising an art of such universal service in modern life.

The Pitman System. Briefly stated the two chief causes of the present position of shorthand are these:

1. The Pitman system of shorthand is founded on a philosophical basis, approved by Max Müller and other eminent authorities on the representation of language in writing, while, as the result of its use by a host of able shorthand writers in every field of work, the system has been developed on lines of practical usefulness to a far greater extent than any other method.

2. Ever since the advantages of shorthand were fully demonstrated, there has been a progressively increasing demand for the services which this useful art in the hands of competent practitioners can render, particularly in association with literary and commercial enterprise of every description. There are now very few positions involving any considerable use of the pen, in which it is not one of the conditions that the worker shall have a knowledge of shorthand, and therefore the cultivation of the art has become general—it might almost be said compulsory—among all those who seek to enter professional or business life.

The student who takes up the study of Pitman's shorthand through the lessons presented in these pages will do so from the latest and most successful presentation of the system, namely that to which the distinctive title of "Twentieth Century" has been given. The question the novice will naturally put is, "Can I learn shorthand?" Assuming that he has had a fairly good elementary education, and is willing to exercise the necessary perseverance, he can unquestionably do so.

The "Alphabet of Nature." The task before him is comparatively simple, namely, that of mastering the use of a set of symbols for representing the English language in a briefer and much more scientific fashion than the ordinary longhand with which he is familiar. When he has thoroughly learned the characters employed and their proper use, practice in shorthand writing and reading will bring proficiency.

By the employment of what has been termed the "alphabet of nature" the English language can be recorded in Pitman's Shorthand with one-sixth of the trouble and time which longhand requires, and with the adoption of the systematised methods of abbreviation developed in the briefest style, this system of shorthand can be written with the speed of the most rapid distinct articulation.

Sound Writing. The name which Sir Isaac Pitman gave to his system was that of Phonography—a term derived from two Greek words meaning "sound writing"—because its notation is based on the sounds of spoken language. The student must, therefore, bear in mind from the outset that in writing shorthand he must represent spoken sounds only, and these by the appropriate signs provided in the system. For example, if he wishes to write the word *knee* (commonly spelt with four letters, though made up of only two sounds), he needs to use but two phonographic signs, namely, that for the consonant *n* and that for the vowel . *ē*, thus, *knee*. To spell in this fashion a mental analysis of the sounds of words must be made, but this process is very easily acquired, and is soon exercised without conscious effort.

In doing the work prescribed in the present course of lessons, the student should use a pen and ruled paper having a smooth surface. The consonants should be written about one-sixth of an inch long, as in these pages. The student should hold his pen as for longhand writing, but the elbow should be turned out, so that the letter *b* can be struck with ease. He should hold the pen lightly. The wrist must not be allowed to rest upon the note-book or desk. In order to secure the greatest freedom of movement, the middle of the fore-arm should rest on the edge of the desk. The writer should sit in front of his work, and should have the paper or note-book parallel with the edge of the desk or table. For shorthand writing the nib employed should not be too stiff, but, as the thick and thin characters of Phonography need to be made quite distinctive, it must have a sufficiently fine point for this purpose.

TABLE OF CONSONANTS.

Letter.	Character.	Name.	As in	
P		pee	ro*p*e	*p*ost
B		bee	ro*b*e	*b*oast
T		tee	fa*t*e	*t*ip
D		dee	fa*d*e	*d*ip
CH		chay	e*tch*	*ch*est
J		jay	e*dg*e	*j*est
K		kay	lee*k*	*c*ane
G		gay	lea*gue*	*g*ain
F		ef	sa*f*e	*f*at
V		vee	sa*v*e	*v*at
TH		ith	wrea*th*	*th*igh
TH		thee	wrea*the*	*th*y
S		ess	hi*ss*	*s*eal
Z		zee	hi*s*	*z*eal
SH		ish	vi*c*ious	*sh*e
ZH		zhee	vi*s*ion	trea*s*ure
M		em	see*m*	*m*et
N		en	see*n*	*n*et
NG		ing	lo*ng*	a*n*ger
L	up	el	fa*ll*	*l*ight
R	down up	ar, ray	fo*r*	*r*ight
W	up	way	a*w*ay	*w*et
Y	up	yay	a*y*ah	*y*et
H	down up	hay	ad*h*ere	*h*igh

The Consonants. For the representation of words in shorthand the familiar division of letters into consonants and vowels is made, but with this difference, that the Pitman alphabet provides a sign for each of the thirty-six broad typical sounds of the English language and assigns to each a definite sign, which is used invariably to represent that particular sound.

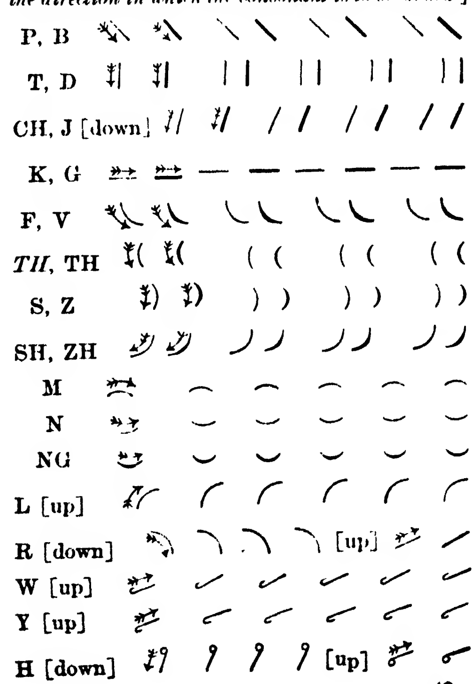
In the ordinary longhand alphabet there are twenty-six letters only, with the result that some of them represent several sounds, and thus occasion difficulties in spelling which do not arise in the use of a complete phonetic method of notation such as we have in Phonography. The consonant signs in the Pitman system number twenty-four (represented by geometrical strokes) and the vowel signs twelve (represented by dots and dashes). Every syllable or word is made up of one or more consonants and one or more vowels. For example, the consonant *p* standing by itself indicates a sound only, but if a vowel is added, thus , we have the word *pay* represented.

How to Memorise the Alphabet. In this lesson the student is introduced to the consonants only. He is required to commit to memory the consonant sounds, and to learn to write them with facility. In order to accomplish this, he must make a careful study of the table, so that he may understand thoroughly what the characters represent, and he must then memorize them *by the names given to them*. This can be best accomplished by pronouncing aloud the names of the consonants when writing the exercise. The student should not take the whole list at once, but should attack it in sections; first the eight straight characters, then the next eight curved characters, and then the final ten signs.

The first sixteen consonants form pairs; thus, *p* and *b*; *t* and *d*; *ch* and *j*; *k* and *g*; *f* and *v*; *th* and th; *s* and *z*; *sh* and *zh*. The articulations in these pairs are the same, but the sound is light in the first and heavy in the second consonant of each pair. Each pair of consonants is represented by similar strokes, but that chosen for the second is written *thick*, instead of *thin*; as *p*, *b*, *t*, *d*, *f*, *v*, etc. We have, therefore, a *light sign* for the *light sound*, and a *heavy sign* for the *heavy sound*. Thick strokes are never written upward. The consonants *chay* and *ray* are somewhat similar in appearance. It is impossible, however, to mistake one for the other, inasmuch as *chay* is always written DOWN, while *ray* is always written UP; thus *chay*, *ray*.

EXERCISE.

[*To be written by the Student. The arrow shows the direction in which the consonant is to be struck.*]



How to Make the Characters. In order to become a neat and graceful writer of shorthand, the student must zealously observe the rule of "drawing" the characters for some time, because unless he does he cannot become a good writer of the system. He should not be discouraged if at first he cannot make the characters "as fair as print." Constant practice and observance of the rule of slow and careful writing will soon enable him to do that.

Having thoroughly mastered the table of consonants, and acquired the ability to write any character without hesitation, the student will proceed to the joining of consonants, a process which demands careful work at the outset, and a strict adherence to the rule of drawing the characters. An important rule to be remembered is: "Observe the angles." In combinations like

rr rp pr klm tk kt brbr drt

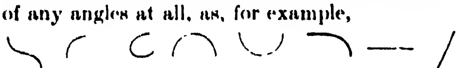
ktrt mrd ch k ntrt

etc., the angles are, of course, easy enough to make; but in combinations such as

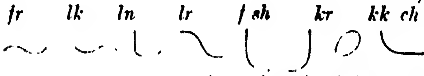
jnr nr fr yrk kr lr rk rm

mr lm

etc., if the student is not from the first very careful in making the angles, he will find later on that he cannot read what he has written without a great deal of trouble. Of course, there are some combinations which do not admit of any angles at all, as, for example,



fr lk ln lr f sh kr kk ch ch



mn nm tn rf tf t sh l sh fk

etc., all of which must be written with a single inflection of the pen.

All the examples given in this lesson should be carefully copied out, and the following rules mastered.

Rules for Consonants. Consonants when joined should be written without taking the pen from the paper, the beginning of the second consonant joining the end of the first; thus,

tk, not *fm, pk, tl, lt, pl,*

lp, sk.

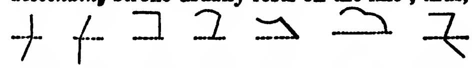
Consonants when joined are written in the same direction as when standing alone, up strokes being always written upward, and down strokes downward; thus,

 *mt,* not 
L and *sh,* however, when joined to other strokes, may be written either upward or downward, under rules which will be explained later. The following are examples of the joining of these consonants:

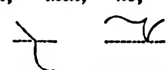
lm, . lm, lk, lk, l ng, sh f, sh m,

sh l, l sh.

In a combination of consonants, the first *descending* stroke usually rests on the line; thus,



t ch, ch t, kt, mch, nb, mr, k ch p,



ptf, m n th l.

An *ascending* stroke beginning a combination should commence on the line; thus,

lp, rr, wk, yr, hf, ylp,

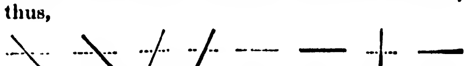
rmn, rlv.

A horizontal stroke followed by an ascending stroke is written on the lin thus,

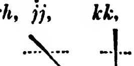
mr, mlr, nr, kl, kr,

gl, kw.

When a straight consonant is repeated, there must be no break between the two letters; thus,

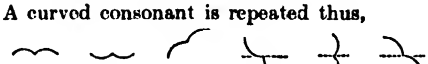


pp, bb, ch ch, jj, kk, gg, td, kg,



bp, dt.

A curved consonant is repeated thus,



mm, nn, ll, ff, ss, rr.

As already pointed out, *chay* is always a downstroke and *ray* always an upstroke; moreover, when *ch* and *r* stand alone, *ch* slopes a little from the perpendicular, and *r* slopes a little from the horizontal; thus,  *ch,*  *r.* The stroke naturally takes these slopes when struck downward and upward respectively.

When *ch* and *r* are joined to other strokes, they are distinguished by the direction of the stroke, and the amount of slope is of no importance; thus,

p ch, pr, ch t, rt, ch n, m ch, mr.

BY

HENRY ADAMS, Thirty-five years Professor of Engineering at the City of London College, Examiner for the Board of Education and the Society of Architects.

THE CHARACTERISTICS AND PROPERTIES OF TIMBERS

By Professor Henry Adams

WOOD is, perhaps, the most widely diffused, and the most generally useful, constructive material in existence. From prehistoric times it has entered more or less into the construction of every human habitation, and it therefore forms the most fitting subject for our first consideration.

All trees are divided by botanists into three classes—*Exogens*, or outward growers; *Endogens*, or inward growers; and *Acrogens*, or summit growers—according to the relative position in which the new material for increasing the substance of the tree is added—whether towards the outside, the inside, or the top. Typical trees of each class would be the oak, the palm, and the tree-fern, and the inverse order would give approximately the historical order of their development in the course of Nature.

The Most Useful Class of Timber. The *exogenous* class is the latest and most highly developed product, and the most useful. It is this class which furnishes the timber in general use for construction, the term "timber" including all varieties of wood which, when felled and seasoned, are suitable for building purposes, and, generally speaking, for cabinet work also. An examination of a few sections will show the typical construction, and, while every variety shows some difference in detail, it will be seen that they all have certain features in common.

If the stem of an exogenous tree be cut across, it will be found to exhibit a number of nearly concentric rings, more or less distinct; and, in certain cases, radial lines intersecting them. These rings represent the annual growth of the tree which takes place just under the bark. Each ring consists of bundles of woody fibre or vascular tissue, in the form of long tapering tubes, interlaced, and breaking joint with each other, having a small portion of cellular tissue at intervals. Towards the outer edge of each ring the woody fibre is harder, more compact, and of a darker colour than the remaining portion.

The Age-marks of a Tree. The radial lines consist of thin, hard vertical plates formed entirely of cellular tissue, known to botanists as "medullary rays," and to carpenters as "silver grain." Figure **1** shows the woody fibre as seen in a magnified longitudinal section; **2** the cellular tissue, and **3** a typical section of the stem of a young tree, *a* being the woody fibre, *b* the pith, *c* the medullary rays, and *d* the bark, the three latter consisting of cellular tissue and enclosing the woody fibre in wedge-shaped portions. As the tree advances in age, the rings and rays become more irregular, the growth being more vigorous on the sunny side, causing distortion. As a rule, one fresh ring is added each year, so that the age of a tree may be known when it is cut down by counting the number of rings, but the rings vary in width according to the vigour of the growth during the season. In some trees, such as pitch pine, they are very uniform, while in others such as oak [**4**] they are very irregular.

When the trees are grown closely together as in a forest they are always straighter and taller as a result of their effort to surmount their fellows, and obtain all possible light and air. When grown singly they make handsomer trees, but have more branches, and therefore knots, and become more irregular. Let us glance at the means by which the growth takes place.

The Growth of a Tree. The roots absorb moisture from the soil, which, in the form of a watery fluid called the *common sap*, rises through the fibres of the last deposited annular ring, traversing all the branches and leaf stalks until it reaches the leaves; there it undergoes some change by the absorption of carbonic acid from the air. It then travels downwards again in the form of *proper sap* just underneath the bark, which is expanded by the accession of moisture, and in the cavity so formed a new layer of material is deposited which gradually hardens, and forms a new annular ring which consists

practically of cellulose ($C_6H_{10}O_5$). The part of the wood next the bark is called *sap-wood*, because it contains more or less unaltered sap, and is not only softer, but more liable to decay than the heart-wood, which is drier and more compressed.

Timber trees may be divided into two great classes—*coniferous* trees or pine-wood, and *non-coniferous* or leaf-wood. The first class contains such trees as pine, fir, larch, cowrie, or kauri, yew, cedar, etc., and the second class such as oak, beech, alder, plane, sycamore, chestnut, ash, elm, mahogany, teak, walnut, box, etc.

The Best Period for Felling. If a tree is felled too young the wood will be comparatively soft and liable to decay, while, if left too long, the wood will have become brittle, and decay at the heart will generally have commenced. If felled at maturity the greatest uniformity of texture will be found throughout, and, therefore, the greatest value will be obtained. Only those trunks or branches which reach six inches or more in diameter are reckoned as timber.

The best period for felling is when the vegetative powers are at rest, either midsummer or midwinter in most cases, but in oak trees it is found that the bark may be stripped in the spring, and the tree felled after the new leaves have been put forth and died, thus providing the best condition of the bark for use in tanning leather, and the best condition of the timber for structural purposes.

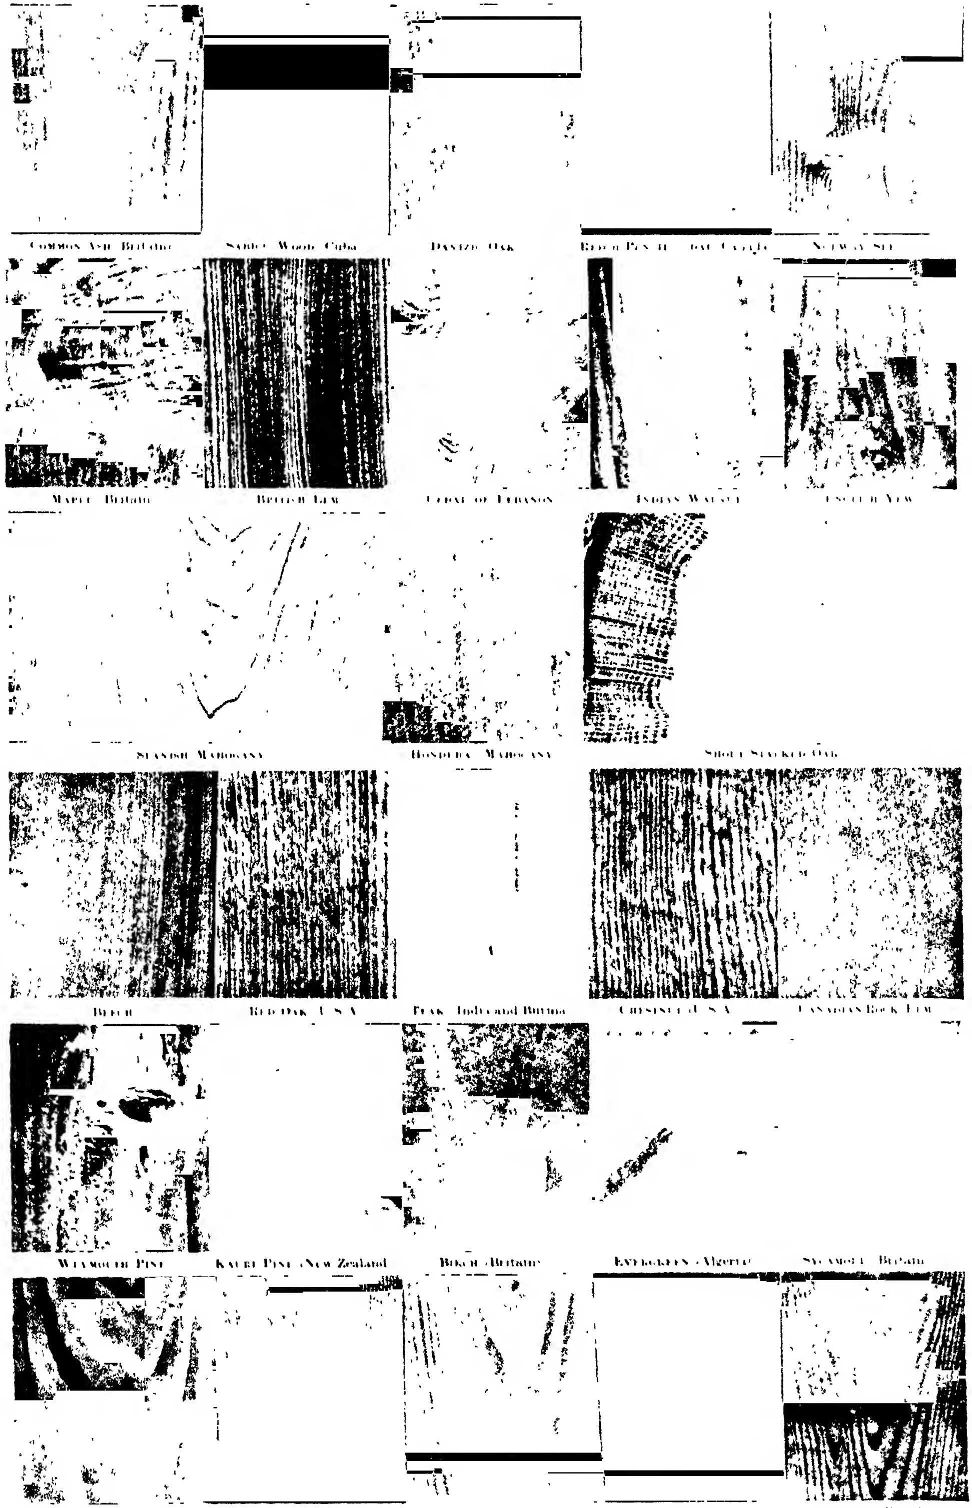
Coniferous trees generally produce softer wood than leaf-bearing trees, and in soft woods the sap-wood is usually of a greenish tinge, while in hard woods the darker they are the lighter is the sap-wood, so that the contrast is very striking. As soon as a tree is cut down it should have the branches lopped off, and then be drawn out into the open and raised off the ground, so that the air may circulate freely round it; if roughly squared it will season quicker, but it should not be cut into scantlings until it is fairly dry.

Seasoning. Timber which is given a proper time for seasoning is tougher and more elastic than that which has been rapidly dried. The newly-felled tree has the fibres more or less distended by sap, but as the moisture evaporates the wood shrinks, and it is very important to understand the mode in which shrinkage takes place. If a round log be cut into planks, as **5**, the process of seasoning will cause a shrinkage circumferentially, so that the planks will take new shapes as shown in **6**. If the medullary rays be compared with the ribs of a lady's fan then the shrinkage is similar to a partial closing of the fan, and an inspection of the grain at the end of a plank will show at once in which direction the distortion and shrinkage will take place. A piece of quartering [7] will show in a striking manner the effect of shrinkage, as in drying it will take the shape of **8**, losing the shaded portion and standing as **9**. The shrinkage in length is so slight that it may be disregarded, but the reduction of width in seasoning may cause a change in the shape of the ends as in **10**, where the dotted lines indicate the change. These effects may all be reduced by carefully drying the timber before converting it, but some varieties—*e.g.* pitch pine, not only go on shrinking in dry weather, but will expand again the reverse way when exposed to a damp atmosphere.

Defects. Timber is liable to numerous defects, principally shakes and knots. Shakes are cracks caused by the partial separation of the fibres longitudinally during seasoning; they are known, according to the shape and position, as heart shakes [11], star shakes [12], cup shakes [13], and wind cracks [14]. Knots are portions of wood where branches have been lopped off, as **15**, but unless they are dead and loose they do not present any serious drawbacks. Rind galls [16] are dead portions shut in by the annual rings, caused by some injury to the sap-wood of the growing tree, and subsequently covered by fresh layers. Sappy corners [17] and waney edges [18] are also defects. Some timber, such as mahogany, is liable to an upset in the grain, as **19**, sometimes called a thunder shake.

Doatiness and foxiness are dirty spots and stains in the cut timber, which may be taken as symptoms of incipient decay. Dry rot is a disease which causes the destruction of the interior fibres and converts the timber to a brown powder, but often leaves a shell of apparently sound material on the outside. Sap-wood and wood that has been insufficiently seasoned is most liable to it, and particularly if situated in a moist, close, stagnant atmosphere, as under a kitchen floor. It is generally associated with a fungus (*Merulius lachrymans*), which spreads over the surface and is very difficult to eradicate. If the evil has not gone too far it may sometimes be stopped by scraping the parts affected and painting them over with blue vitriol or sulphate of copper ($CuSO_4$), and inserting air-bricks in the walls. In bad cases the whole of the affected wood must be cut out and the walls scraped clean, as the fungus, if left for any time, is liable to spread over brickwork and masonry, and produce spores that may attack fresh wood.

Precautions Against Disease. There are various modes of rendering timber less liable to the attacks of disease, or of parasites, to which we may give attention. For outdoor use creosoting is, perhaps, the most important. This was formerly known as Bethell's process, and consists in impregnating the timber with creosote or oil of tar. It is usually performed in a closed wrought-iron cylindrical vessel, like the shell of a Lancashire boiler, say 7 feet diameter and 60 feet long, with a door at one end and tram rails laid along the bottom inside. The balks or planks of timber are placed upon trollies with chains or iron hoops over the top to keep the timber from floating when the creosote is let in, and the trollies are run into the cylinder. The door is then shut, and a vacuum of 7lb. or 8lb. per square inch is created to extract the air from the fibres. After a short interval creosote is allowed to enter, the vacuum is maintained until all the timber is submerged, and the pressure is then raised to about 150lb. per square inch. An average of 8lb. of creosote per cubic foot of



Common Ash (Britain) — Satin Wood (Cuba) — Dantzic Oak — Red Pencil Cedar — Norway Spruce

Maple (Britain) — British Elm — Cedar of Lebanon — Indian Walnut — English Yew

Spanish Mahogany — Honduras Mahogany — Short Stacked Oak

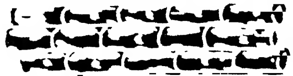
Beech — Red Oak (U.S.A.) — Teak (India and Burma) — Chestnut (U.S.A.) — Canadian Rock Elm

Weymouth Pine — Kauri Pine (New Zealand) — Birch (Britain) — Evergreen (Algeria) — Sycamore (Britain)

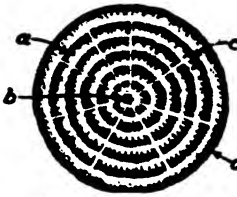
Larch (Europe) — Italian Larch — Dantzic Fir — Pitch Pine — Canadian Red Pine

THE TIMBERS OF COMMERCE

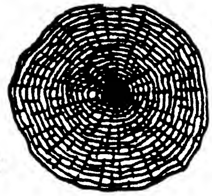
1. Woody fibre, magnified.



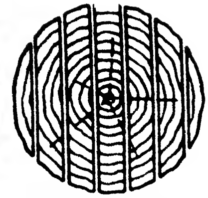
2. Cellular tissue.



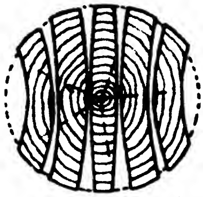
3. Section of young tree.



4. Section of oak.

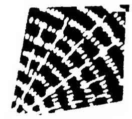


5. Section cut into planks.

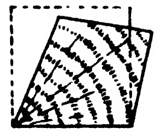


. Planks after seasoning.

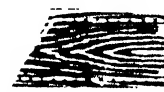
7. Quartering.



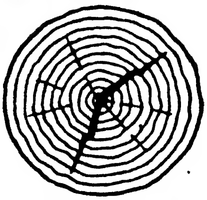
8. Shrinking.



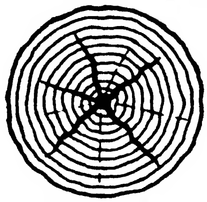
9. Form after shrinking.



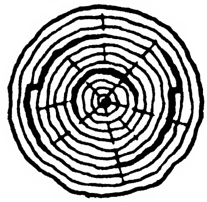
10. End after shrinking.



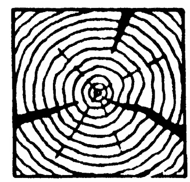
11. Heart shakes.



12. Star shakes.

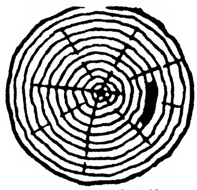


13. Cup shakes.



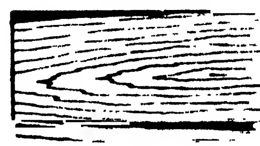
14. Wind cracks.

15. Knots.

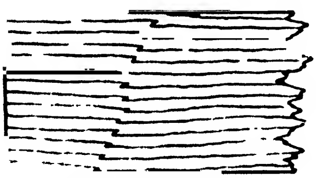


16. Rind gall.

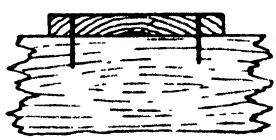
17. Sappy corners.



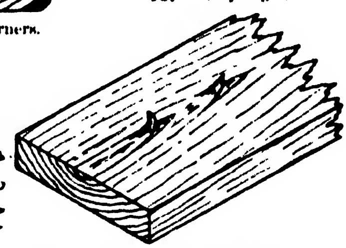
18. Waney edges.



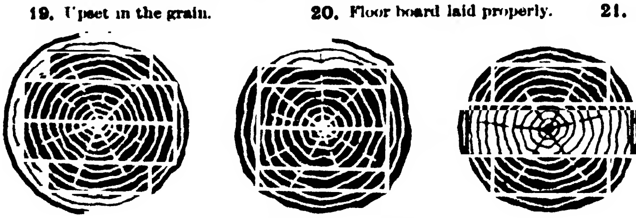
19. Upset in the grain.



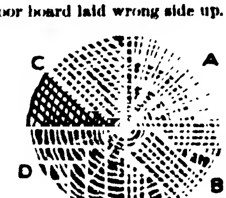
20. Floor board laid properly.



21. Floor board laid wrong side up.



22, 23, 24. Cutting pine and fir.



25. Methods of cutting oak.

26. The flower of the oak.

27. Cutting pitch pine for panels.

timber can in this way be forced in, and it remains there after the timber is removed.

This process is used mostly for paving blocks, for railway sleepers, for timber piles, and for jetty work, the strong smell rendering it unsuitable for indoor purposes. The Fire Resisting Corporation, Ltd., by a somewhat similar method, impregnate timber with an antiseptic and fire-proofing solution, which is forced into the fibres by hydraulic pressure. The trolleys are then run into a drying kiln, where the timber remains for about a month before it is ready for use. By the Powell process timber of all kinds, including cabinet woods, is placed in a saccharine solution, which has the effect of producing a chemical alteration in the sap, so that even green sappy wood can be rendered perfectly sound, and after drying is free from any tendency to shrink, warp, or decay. Many other processes have been tried with more or less success, but they have now fallen into disuse. The more open the texture of the wood the better it can be impregnated, and hence the various processes have been almost exclusively applied to Memel and Dantzic fir.

The Timbers Most Used. We will now turn to the different kinds of timber in ordinary use, beginning with the coniferous class, having spines instead of leaves, and bearing their seeds in the so-called "cones" of various sizes.

The most useful member of this class is the *Pinus sylvestris*, which is popularly known as Northern pine, Scotch fir, Baltic fir or pine, and red or yellow deal. The uninitiated have great difficulty in understanding the use of the terms fir, deal, and pine; *fir* should be used only for the products of the *Abies*, but it is used by carpenters for any soft timber used in scantlings—*i.e.* above 2 inches square, and it is used by quantity surveyors for any unwrought wood where the same piece would be described as deal if wrought—*e.g.* fir rough fillet or deal wrought fillet. The term *deal* again is used both for pine and fir, with the distinctive prefix of yellow and white respectively. Deal also signifies the size of a board—viz., 9 inches wide, planks being 11 inches wide, battens 7 inches, and narrow battens 4½ inches. The term *pine* is likewise used for various kinds of clean straight stuff, including yellow deal, red deal, patternmakers' pine, and pitch pine. The wood of the *Pinus sylvestris* is of a honey yellow with the annual rings rather darker, and giving figure to the wood when wrought. Some varieties turn a pinky-red when wrought, and this probably gives the name to red deals. It is, as a rule, straight-grained and very free from knots, and is known by the name of the port from which it is shipped.

Deal. The yellow deals from Christiania are considered the best, but they sometimes contain a large proportion of sap-wood. Those from Stockholm and Gefle are next in quality, but are more disposed to warp than Christiania deals. They are suitable for floors and other work where warping can be prevented. Stockholm and Gefle yellow are generally used for ground floors; Dram and Christiania white for upper floors. All floor boards should be laid heart side downwards, the curling being prevented by nailing the edges, as **20**; if laid otherwise, pieces in the centre, where an annual ring crops out, are apt to shell up [**21**] when the floors are washed. Swedish deals cannot be depended upon for joiners' work, owing to their extreme liability to warp. Gottenburg deals, though strong and durable, are not suitable for joiners' work. Archangel and Onega produce good deals for joiners' work, but they are not so durable in damp situations as Christiania deals; they make good warehouse floors and staircases. The best Russian deals in the market are those from Viborg, but they are inclined to sap; those from Narva and Petersburg are generally inferior. The knots in Russian deals are apt to be surrounded by dead bark. Memel is a very uniform and durable timber, imported in the log and very suitable for carpenters' work. The size, averaging 13½ inches square, makes it very convenient for use in civil engineering constructions, such as jetties. Dantzic timber, also in the log, runs to larger sizes up to 16 inches square; it has a coarse growth, and is generally full of large knots, often dead, and is subject to cup shakes. Riga logs are now seldom seen; they are the most uniform in quality, but do not run over 12 inches square. Swedish timber is generally deficient in resinous matter, and cuts with a woolly surface, but some of it may have thick annual rings and a quantity of resinous matter, which chokes the saw. Good timber, when freshly cut, should look clear and bright to the eye, and be firm and dry to the touch.

Pine. *Pinus rubra*, Quebec pine, Canadian red pine, or American red pine is very like Memel, but when knots occur in it, they are larger than in Memel. It is a clear, straight timber—soft, pliant, and easily worked—but not so strong or durable as Baltic pine. It is much used for joinery and mouldings.

Pinus strobus, American white pine, American yellow pine, Weymouth pine or soft pine, is much used for all purposes in its native country, but in England it is very liable to decay. There is scarcely any difference, either in colour or texture, between the inside and outside of the annual rings; it is clean, straight-grained, free from knots, and grows to a very large size. When freshly cut, the wood is perfectly white, but soon assumes a brownish tinge. It can always be recognised by short hair-like marks or black dashes in the grain. It is chiefly used by pattern-makers, and hence is known by the name of pattern-makers' pine; it is also used for door panels, on account of its width, but it is too soft for joiners' work in general.

There are several other varieties of pine occurring in smaller quantity. They are used as timber, but we need not specify them. One large class, however, known in England as pitch pine, needs consideration. The principal variety is, perhaps, that named *Pinus Australis* or Southern pine, or Georgia pine, found over a large tract of country in the United States. It is very resinous,

straight-grained and hard, free from knots, with the annual rings very regular and strongly marked. It is used for deck planking, treads of stairs, and similar purposes where its hardness and toughness are advantageous. It is also used for furniture, on account of its freedom from knots and strongly-marked grain. About one log in a hundred is found to have a beautiful curly grain, due to irregularities in the annual rings, and these logs are reserved for panels, which are, however, difficult to work, as the grain is apt to tear up. It is not good for beams, although very strong when new, as in course of time the resinous matter evaporates or dries up and the wood gets brittle. It is also not good "between wind and water"—*i.e.* for jetty and dock work—and not good for window-sills, although often used. It must be well seasoned before use, as it is particularly liable to shrinkage.

Fir. *Abies excelsa* or *Picea excelsa*. Spruce fir, or white deal, is largely imported into this country from Norway and Sweden, and from other Baltic ports. The best qualities are used for joiners' work and the common qualities for rough inside work. Christiania white deals and battens are best for panelling, for dresser tops, shelves, and the upper floors of houses; those from Friedrichstadt have small black knots; those from the lowland districts of Norway warp and split in drying.

The most durable timber is grown on the higher ground and the more northern latitudes, the growth is slower, and the wood is consequently more compact. Both good and bad deals come from Dram, known as Drammen deals. Gottenburg white deals are very stringy, with a woolly surface, and are used mostly for packing-cases. Narva supplies the next best to Norway, and Riga follows. Petersburg white deals are said to shrink and swell with changes of weather, even after being painted.

Young trees of spruce fir with the bark left on are used for scaffold poles; they may be obtained from 6 to 8 inches diameter and 30 to 60 feet long. The same poles cut down the middle are used for making ladders, straight grain being thereby assured. The wood of the spruce fir is light, elastic, tough, not difficult to work, and some varieties are very clean and free from knots, though when knots occur they are generally very hard and notch the plane-irons. The colour varies from pale yellowish to brownish white, the commoner qualities being almost perfectly white, and all turn bluish when exposed to the weather. There is very little resin in the grain, but it sometimes occurs in bold open streaks. Carpenters distinguish the qualities by calling the better ones white deal and the commoner ones spruce. Other varieties of this tree are the American white spruce, American black spruce, Canadian or hemlock spruce, Nova Scotian red spruce, and the silver fir. They are not much used in England.

Larch. *Larix Europæa*, or common larch, is an extremely durable timber in all situations. It is a very resinous wood, and the resin often exudes to such an extent as to form a varnish on the exterior, protecting it from the weather. It is particularly suitable for posts and sleepers, but, on account of its resinous nature, does not dry very readily, which renders it liable to shrink and warp if cut into boards. It is well adapted for floors and staircases, where there is much traffic. It bears driving bolts and nails better than any other resinous woods, and therefore makes good ship timber. The wood is of a honey yellow, the hard part of the annual ring being of a reddish cast similar to Memel, but more pronounced, and, on the whole, it has a browner appearance.

Cedar. *Cedrus Libani*, or Cedar of Lebanon, is one of the most durable timbers, of a yellowish brown, with distinct annual rings, powerful odour, and slightly bitter taste. It is straight-grained and easily worked, but liable to split. The cedar in common use is, however, the Virginian red cedar (*Juniperus Virginiana*). This is largely used for wardrobes, drawers and boxes, as the taste and smell keep away insects. It is the well-known wood used for covering blacklead pencils, and hence is often called pencil cedar.

Yew. The common yew (*Taxus baccata*) is a beautiful wood for cabinet-making, but takes a long time to dry. Where it is plentiful it is very good for fencing. The cypress (*Cupressus sempervirens*) is an ornamental evergreen tree often found in English churchyards. It is here slow growing and does not attain a large size, but in the South of Europe it grows larger, and is supposed to be the most durable of all varieties of timber.

New Zealand Pine. The New Zealand pine (*Dammara Australis*) is a coniferous tree that deserves to be better known. It is said to grow to a height of 80 to 140 feet, with a straight, clean stem 4 to 8 feet diameter. Although it contains a considerable amount of resin, this exudes while the tree is growing, so that it is not particularly noticeable when the log is converted. The wood is close, even and fine-grained, the texture uniform and slightly mottled, the colour a light yellowish brown or full honey yellow, with a silky lustre, and the annual rings are only slightly marked. It cuts very uniformly in any direction, is easily worked, and yet tolerably hard. It unites well with glue, but is apt to split in nailing. It is used in England principally by pattern-makers for patterns for small brass work, but makes beautiful panels for yacht cabins, and might be used largely by cabinet-makers and joiners.

Hurst's edition of Tredgold's "Carpentry" may be consulted for much useful information relating to timber and its uses. The marks upon timber have not been referred to, as they are so numerous and frequently change, but they have to be known in making purchases, as they nearly all indicate some specific quality.

Oak. Among the non-coniferous trees, or hard woods, oak (*Quercus*) is the most important. There are three principal varieties grown in England—the Old English oak or stalk-fruited (*Quercus robur* or *Quercus pedunculata*), which may be known when growing by the acorns having long stalks and the leaves short stalks;

the Bay oak, or cluster-fruited (*Quercus sessiliflora*), whose acorns grow in close clusters with very short stalks, the leaves having longer stalks; and the Durmast oak (*Quercus pubescens*), whose acorns and leaf stalks are similar to the Bay Oak, but the leaves are somewhat downy on the underside.

The timber from the stalk-fruited oak is considered to be superior to the others; it is lighter in colour, has a straight grain generally free from knots, and has numerous and distinct medullary rays, and consequently good "silver-grain" or "flower." It is easier to work and less liable to warp than the bay oak, it splits well and makes good laths, and it is suitable for all kinds of work. The wood of the bay oak is darker, tougher, heavier and harder, but has few large medullary rays, and is liable to warp. Durmast oak is inferior to either. Quebec oak or American oak (*Quercus alba*), called white oak from the colour of its bark, has a pale reddish brown colour with a straighter and coarser grain than English oak, is sound, hard, and tough, and bends easily when steamed. Dantzic oak is of a dark brown colour, with a close, straight and compact grain, bright medullary rays, free from knots, very elastic, easily bent when steamed, moderately durable.

Riga oak is similar, but has more numerous and more distinct medullary rays; it is imported in half round logs. Italian oak is brown, hard, tough, strong, subject to shakes and difficult to work, but free from other defects. Wainscot oak is timber so converted as to show the silver grain, or flower, to the best advantage. Clap boarding, imported from Norway, is a sort of inferior wainscot, distinguished from it by being full of white-coloured streaks. Oak is a good all-round timber in point of strength, durability, and general application; it stands exposure to the weather better than most others.

Chestnut. The chestnut used for building purposes is the Spanish chestnut (*Castanea edibilis*), not the common horse chestnut, which is a spongy, whitish wood of little or no use. The Spanish chestnut is only grown to a small extent in this country at the present time; it may be known by the leaves being smoother, darker, longer, and separated more distinctly. The wood is much like oak in colour and general appearance, but has rather more of a cinnamon cast of colour, less sap wood, and generally a closer grain, although softer and not so heavy as oak. The chief distinguishing characteristic of the chestnut is the absence of the distinct medullary rays, which produce the flower in oak, and old roof timbers, benches, and church fittings may be discriminated in this way, also by the chestnut being more liable to split in nailing, while the nails never blacken the timber from the formation of ferro-gallic acid as they do in oak. Reports vary, but the general opinion is that the roof of Westminster Hall is oak, and the circular part of the Temple Church of chestnut.

Beech. Beech (*Fagus sylvatica*) is a close-grained hard wood, with remarkably distinct medullary rays in small plates, showing when cut across as small strokes. The wood is a whitish-brown, very suitable for machinery, for the stocks and handles of tools, and for many other purposes. It soon decays when exposed to alternate drought and moisture, and is very liable to the attacks of worms. For cabinet-making it is stained to represent rosewood and ebony; it is also used by glass-blowers on account of its freedom from deleterious matters; engineers use it for piles under water and for wedges.

Elm. Elm (*Ulmus campestris*) is a very open-grained wood of a reddish-brown, and is generally much twisted in the grain. It is fibrous, dense, and tough, and bears driving nails very well. It is not used in small scantlings on account of its liability to warp; it is useful for piles and for planking in wet foundations, but decays rapidly if exposed to alternations of moisture; it is much used for pulley-blocks, naves of wheels and coffins. The American elm (*Ulmus racemosa*) is much lighter in colour than the common elm and of a different character, being clean and straight in the grain, tough and flexible, free from knots and sap, and can be wrought with a fine smooth surface. It is much used for ships' rails and for the fender pieces of jetties.

Ash. Ash (*Fraxinus excelsior*) is a light brownish white with longitudinal yellow streaks, each annual layer is separated from the next by a ring full of pores. It is remarkably tough, elastic, flexible and easily worked, with very little sap wood, but requires to be sawn into planks soon after felling, as otherwise deep shakes open from the surface. The planks should be stacked with small fillets between, so that they may season without warping. It is very useful for long tool handles, shafts, spokes and fellows of wheels, wooden springs, and wherever it has to sustain sudden shocks. It is very durable if kept dry, but soon rots when allowed to become alternately wet and dry, and is subject to the attacks of worms. It is used for wardrobes and other cabinet work on account of the colour and figure of its grain.

Birch. Birch (*Betula pendula*, *B. alba*, etc.) has a straight grain and sometimes well figured. It is hard and tough, stands wear and tear; is an excellent wood for the turner, being light-coloured, compact, and easily worked; is much used in cabinet making and for furniture of various kinds; when stained and varnished it is not easily distinguished from mahogany. American birch is used for putlogs. Russian birch, called also Russian maple, is well figured and of a full yellow colour.

Mahogany. Mahogany (*Mahogani swietenia*) is obtained from Central America and the West Indies. The former is known as Honduras mahogany, and the latter as Spanish mahogany. Honduras mahogany is similar to cedar in colour, of somewhat straight and coarse grain, makes soft silky shavings, and is worked with very little waste, if care has been taken in seasoning. It makes very good panels in

importance of educational travel upon its readers, and indicating how best to pursue this important branch of self-education.

Travel and Book-knowledge. We dare venture to say that if we were to describe travel as the most valuable part of any man's education we should not be greatly over-estimating its importance. It is difficult to think of any occupation, requiring skill and observation, in which the worker would not be the better fitted to engage if he had some intelligent travel in a foreign country. True, much may be learned from books, and reading about other lands and peoples must go together with visiting them. We have met persons who, never having visited a foreign country, were still, thanks to their book-knowledge, better informed concerning its manners and customs, its people and their history, than others who had often been to that country, but who had travelled without profit; tourists, in a word. One of the finest descriptions of Italy ever penned is to be found in "John Inglesant," and at the time he wrote it the late J. H. Shorthouse had not been across the Channel. Many such instances might be given; yet all combined would form no argument against our case for the educational value of travel, just as the gaping tourists who never acquire any real knowledge of the places they visit and the people they see must not be quoted against us, since we submit that they are not in any true sense of the word travellers. They are to the man who travels for education, or intelligently, as the gobbler of cheap library fiction is to the serious student of books.

The "Wander-Year." One of the reasons for the enormous advance industrial Germany has made in our time is to be found in that old Teutonic custom, the Wanderjahr, or Wander-year. As soon as an apprentice is out of his time, he fares forth on a year's wandering through the country, plying his craft in different towns and villages, and gaining thus a breadth of mind and experience which is invaluable to him in after-life. Such a youth is worth far more in resource and knowledge than a workman who has never been beyond a day's journey from home, be the latter never so diligent. He is, indeed, the veritable "journeyman," and can we wonder that a nation of such journeymen advances? The Wanderjahr also serves to implant in the German that intense love of travel which is so characteristic of the people. One cannot wander about the Continent any summer without encountering little groups of young Teutons with their knapsacks and stout staffs; pilgrims of knowledge.

So vitally important to the growing prosperity of any country is an enlightened and alert people, that it is surprising our educational leaders have not in the past insisted more strenuously on the absolute need of foreign travel as a part of general education, instead of leaving it to flourish chiefly as a pleasure or a pastime. True, it were a most desirable thing that certain features of education did become popular as pleasures: the study of languages, for instance; but, broadly speaking, that which is carried through *entirely* in the spirit of pleasure, and chiefly with the desire to amuse or to pass the time, is not calculated to leave on the mind any real educational effect.

Serious Holidays. We do not wish to be held as urging that pedagogic travel should take the place of all other recreations; no view so extreme has been present for a moment in our mind. But what we do contend for and should delight to help in bringing about is, that young people, and indeed all who can still travel either at home or abroad, would regard their annual vacations with less of levity and with a thought more of seriousness than they are, for the most part, at present apt to do. For this touch of serious purpose to what may still be pleasure of the most desirable and enduring kind would have a wonderful effect in raising the national standard of enlightenment; incalculable. Holidays should not be merely the annual recreation of Jones, Brown, and Robinson; but the annual recreation of a whole people, a process that should help to fit them the better for their part in the world's work and destiny. It is this wide national view of a matter, that is only individual because the State is made up of individuals, which we are anxious to urge before we come to the closer consideration of its bearing on the character and career of the average citizen.

A National, not only a Personal, Matter. Assuredly it is no mere personal matter, this of educational travel. It is eminently national in its importance. And to Britishers more than to any other nation, as our insular situation renders us peculiarly liable to cherish erroneous opinions of the world's economy. Inversely, our insular circumscription has made us the world's colonisers. Our bolder spirits in times past, and not less to-day, have from the very fact of our territorial limitations sighed for wider realms and adventured into far lands with the wondrous results of which we are all so proud,—many of us with so little personal reason. The Scots are pre-eminently the colonisers of the British Empire —in Canada, Australia, the Cape, everywhere, the Scot is prominent, because his own land is so small and so lacking in riches that he must travel to distant parts if he would improve his condition. To the Frenchman, the German, the American, it is almost enough that he travel his own great land; yet not enough, wide and abundant in interest as these countries are, for there are thousands of clerks in the United States who do not know the postage rates to England, all their interests being so exclusively American; it is possible to be insular in one's knowledge and yet to live on a great continent. Still, the countries named, and especially the United States, have far more to offer their citizens who confine their travels to them than England has for Englishmen. A Frenchman who knows France from Maubeuge to Marseilles, from Nancy to Nantes, knows more of the world and humanity than an Englishman who knows his native land from the Tweed to the Solent—and he is not more rare. Knowledge of our own country is not to be despised; in fact, it must come before foreign travel, and

we will assume in all that follows that the reader is reasonably familiar with his own land; but one short journey to the Continent, if his eyes be open and his mind likewise, will teach him more than a lifetime in England. Yes, more of England!

"What should they know of England who only England know?"

Why We Must go Abroad. It has been well said that the whole art of painting a picture is knowing just where to sit down. That is, how to get the point of view. Similarly, the art of knowing how to appreciate and to understand one's own country lies in choosing the point of view, and it needs no insistence to advance the proposition that in order to come by this point of view one must go outside the country. We may be participants in a procession and know nothing whatever about that procession. "The looker-on sees most of the game." *To see* England, go to France, Germany, anywhere but England. That is the best way, the only way, to intelligent patriotism. As nothing is appraisable save relatively, or by comparison, we must know something of the life of other peoples, the characteristics, natural and social, of other lands, before we can presume to estimate these qualities as they are exhibited in our own land. All this is so obvious, that it seems to be unnecessary to set it down; but that is precisely why the need exists, as it is the obvious which people are most apt to ignore or to omit to profit by. Certainly these very obvious considerations are by no means present in the minds of the majority of British people, or, at least, there is no evidence in their actions that they are influenced by them.

How Travel Modifies our Ideas. In Manchester, Liverpool, Birmingham, Glasgow, Leeds, and other great provincial centres, we should have no difficulty in finding thousands of young men and women who have never visited London. Think how some first-hand knowledge of London ways must correct and modify the local impressions of these young people. Then consider how similar knowledge of Paris, Brussels, Berlin, Madrid, and Rome—or any single one of these capitals—would, by many times multiplied, modify their impressions of things. Why, in the day that a young man steps ashore at Calais he has done far more than he ever did when he passed into a higher class at college. He has opened the door of his mind to the entrance of the newest knowledge in the world: *his own* impressions of a foreign land. Of itself this may seem a small thing, but in its effect upon an intelligent and ardent mind it is an immense thing. That mind will never again think of England and of life from the insular point of view; cannot. It is not at all necessary to go far afield to intensify the impression: Egypt will serve hardly better than Belgium, not so well as Rome or Etruria, in vivifying the spirit of antiquity. A stay of a week in Bruges, in Ghent, in Ypres, combined with the book-study of these old towns, once so magnificent and so populous, now shrunken in decay (for even busy Ghent is but a shadow of its former self) would have a wonderfully *quietening* effect upon the mind of a youth who has been reared in the narrow local patriotism of Glasgow or Birmingham; while Brussels, with its splendid boulevards and handsome public buildings, its bright and happy life, would enable him more accurately to gauge the conditions of his own town. This need not, will not, make the young mind less patriotic, but more intelligently so, alert to shortcomings and keen to remedy them. In point of fact, we have only to notice how frequently the corporations of our large towns are sending deputations abroad to study the ways of Continental cities if we wish a ready illustration of the value of foreign travel. Seldom does any British corporation undertake an important public work, a new tram service or water supply, without preliminary study of other towns in their treatment of the same matter. To the intelligent observer there is no foreign town which will not show him many things worth doing or equally worth avoiding.

How it Aids Citizenship and Patriotism. This all makes for better citizenship. The more a man knows of other towns the shrewder is he in criticising his own, the more alive to its faults and equally to its advantages. And these are the citizens that we want to-day: not people proud and arrogant from ignorance, but appreciative and loyal from knowledge, and, seeing what is good in other places, keen to adapt it to their own. In the same way this aspect of foreign travel includes the larger patriotism: the temperate and reasonable loyalty of men and women who love their own land and know it best because they can view it in relation with others. That is the patriotism, above all, we need most now and in the future. For it is clear that Britain has entered upon a new era of international politics, *demanding of her people no purblind devotion to the British flag, but a sympathetic understanding of the other great peoples of Europe,* who are neither fools nor rogues, but nations as highly civilised as ourselves, as honest, as lovable, as human, and perhaps more interesting to us, as we are so to them. It is a wholesome thing to the confident Cockney to discover one day that he too is a "foreigner" when he lands at Boulogne; then begins a process of modifying his Cockney confidence and pride, which, if continued, can have nothing but the most desirable results. If we saw—and we think we can at least see signs of this—the Germans, the French, and the British increasingly keen on travelling in each other's country, not to sneer at, but to observe and to understand each other, *there* would be the best possible guarantee of international peace. For this we must bear in mind: he is a poor traveller who returns to scoff at his own land, and does not always feel ready to adopt those words of Goldsmith, applying them to his native land:

"Where'er I roam, whatever realms I see,
My heart, untravell'd, fondly turns to thee."

The more personal side of foreign travel has been barely touched upon thus far, and will form the subject of our next chapter.

WOOL: AN INDUSTRY OLDER THAN ALL CIVILISATIONS

By W. S. Murphy.

APPARENTLY an artificial product of civilisation, the textile industry has its roots deep in the constitution of the world. The prehistoric beginner of textile manufacture, though most probably unaware of it, was merely imitating one of nature's most common processes.

All animal and vegetable tissues are formed by the combination of slender threads, or fibres, or filaments. When we refer to the fibre and texture of wood, or flower, or flesh, we use no figure of speech, but speak simply of those things as they really are. Thread by thread, nature builds up the tissues of all organisms; she is the original spinner and weaver, and man is her feeble imitator. By microscopic analysis it has been found that the fibres visible to the naked eye are themselves composed of fibres, and that these fibres are made up of smaller fibres still, down to filaments so slender that the human eye fails to detect them.

The Basis of Textile Industry. This principle is observed throughout the process of textile manufacture. If a piece of woollen cloth is separated into its parts, two sets of threads come apart; examination of one of these shows that it is composed of threads still more slender, and these again are found to be composed of thin fibres twisted together. At this point the threads cease to be continuous, and fall apart into a series of fibres which have been combined. Nature's threads and tissues do not fall apart in that way, because her weaving is a vital, organic process, while man's fabrication is purely mechanical.

In comparing the organic texture of natural tissues with the mechanical combinations of textile industry, we do not mean to depreciate human art. Textile industry is based on the fact that certain fibres will mechanically combine so intimately as to form a perfectly homogeneous whole. This is the root quality of the textile manufacturer's raw material, which places in a single category fibres so diverse as cotton and mohair, hemp and silk. With unerring precision the test eliminates the textile from the non-textile fibres. Put, for example, a pair of human hairs beside a pair of wool fibres. Though carefully twined, the hairs come easily apart. Laid carelessly together, the wool fibres cling. A tuft of thistle-down, closely resembling cotton in superficial aspects, can be blown apart by a breath; the fibres of a tuft of cotton wool yield up each other only under delicate yet forcible pressure.

An Aggregation of Industries. The object of textile industry is to form vegetable and animal fibres into threads and fabrics for use and adornment. No one needs to be informed that there are many fibres used in the industry, numerous kinds of thread produced, and fabrics still more numerous. While one great aggregation—ultimately, we believe, to be resolved into unity—the textile industry is divided definitely into great branches, each containing many different trades. If every branch of the industry used a different material proper and peculiar to itself, and observed special methods and processes, classification would be a simple matter; but the two staple processes, spinning and weaving, are common to all, and one manufacture complicates with another in diverse ways, the cotton weaver taking weft from the silk spinner and the carpet weaver getting jute warp from the jute mill, the wool spinner using the cotton spinning mule, and the cotton spinner in turn applying the wool comber to his purposes. This complexity brings out an important truth. No matter what branch of the textile trades a man chooses to follow, he

ought to make himself acquainted with the general principles, at least, of the whole industry.

The Principal Fibres. Textile fibres may be likened to the lines at a great railway terminus; they start parallel and give off one branch after another, finally diverging at the door of the market. The principal fibres are—Wool, Cotton, Silk, Flax, Hemp, Jute, Coir, and China Grass—otherwise known as Ramie.

With the modern growth of the textile industry, and the consequent enormous demand for raw material, attempts have been made to introduce other fibres as substitutes for these; but the selective judgment of mankind seems to have well-nigh exhausted the field. Taking the fibres as termini, we find Wool branching off into Felt, Yarn, Woollen, Worsted, Carpet, and Hosiery Manufactures; Cotton into Calico, Muslin, Fancy Cloth, Sewing Thread, and Lace; Silk into Silk Yarns, Sewing Thread, Ribbons, and Cloths; while Flax, Hemp, and Jute resemble a series of local branch lines, more or less associated, producing, in a variety of combinations, Linens, Damasks, Canvas, and Floorcloths, Sailcloth, Mats, Ropes, and Twine. Before he starts, say, on the Cotton line, that is to bear him far into the heart of the muslin factory, the student should take a careful look at the various fibres employed in the textile industry and note the particular qualities of each. Let us set them down.

WOOL. Hollow tube, clothed with triangular scales set in pairs, giving a wavy character to the structure; soft, bright, firm, and elastic.

COTTON. Flattened tube, sides flanging inward, the whole fibre tending to twist.

SILK. Double tube, covered with clinging gum; soft, bright, and flexible.

FLAX. Built up of transverse layers, showing serration; fine, flexible, but woody in texture.

HEMP. Coarser than flax, but similar in structure.

JUTE. Soft, thick fibre, lustrous; grows to great length.

COIR. Wavy, serrated, coarse, but shows great density of structure; derived from the cocoa nut palm.

RAMIE. Long and slender fibre, with adhesive property; allied to jute; lustrous and transparent.

WOOL AND ITS MANUFACTURE

The Woollen industry is older than all existing civilisations. Like many another art, the manufacture of wool has risen and fallen with the rise and fall of nations.

Who first used the sheep's woolly coat for a garment is unknown. The inscribed tablets recovered from the buried cities of Western Asia and Southern Egypt show that woollen manufacture was practised by nations whose origin and end are unknown. In the very earliest traditions of our race the sheep figures as the useful property of man. We read in Genesis: "And Abel was a keeper of sheep." Job, the hero of the oldest book in the Bible, possessed in the days of prosperity which gladdened his age and repaid his sufferings, 14,000 sheep, and was doubtless a large exporter of wool. Solomon sings of the virtuous woman: "She layeth her hands to the spindle, and her hands hold the distaff." Ancient poetry abounds in reference to the industry. Homer, in the "Odyssey," describes Penelope weaving the shroud of Laertes, while her maidens spin the wool, the faithful wife of the absent hero warding off her importunate suitors by lengthening out her task, unravelling at night what she had woven through the day.

An Ancient Craft. Centuries later, Ezekiel spoke of Tyre as the market of white wool from Damascus and blue cloths from the tribes of Syria. Nineveh and Babylon were great centres of woollen cloth manufacture, and Persia, shorn of her ancient glory, still sends carpets to the palaces and mansions of the West. Lady Lugard has gathered records of vanished African empires, where woollen garments, stiffened with gold, were worn by kings and chiefs. All round the world, "from China to Peru," wool has been used for clothing, for comfort, and for ornamental fabrics, from times beyond the beginnings of recorded history. The woollen industry is, as the old Guild charters say, "a most ancient and honourable craft."

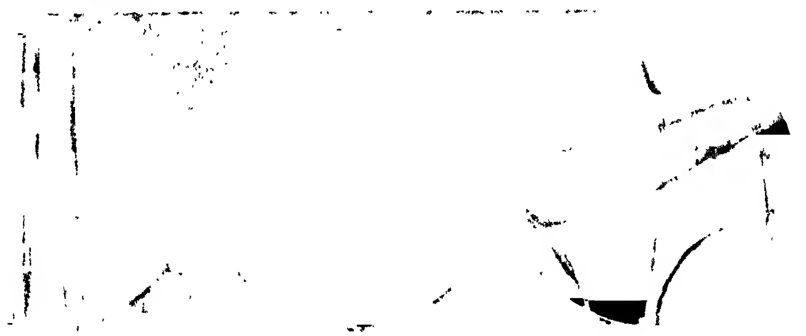
Yet the industry is still developing. The factories of Nineveh have vanished without leaving a trace, but new factories rise every year in Yorkshire and Lancashire; the dyers of Tyre are lost to fame, but their successors work in the laboratories of Vienna, Berlin, Paris, Bradford, Manchester, Massachusetts, and New Jersey. On the sites of Babylonian weaving factories the Arabs felt the tent-cloths with their feet. The old races attained civilised life, perfecting their industries; they sank into barbarism, degenerated, disappeared, taking their industries with them. New races, or races held in reserve, came forward, and found the arena of world-culture empty. Truly we are the heirs of all the ages.

When Caesar came to England. It seems to be proved that, when the ancient Celts came over to the British Isles, they knew the art of felting wool. According to Cæsar, the inland tribes, in 55 B.C., wore the skins of beasts, when they wore anything but paint. He does not mention, however, as appears from other evidence, that the inhabitants of the southern coast wore a short kilt of felted wool. Very probably the inlanders were equally acquainted with the art, but were too busy subduing the land to pay much attention to clothing. A similar difference might have been observed not a hundred years ago between the inhabitants of the American coast towns and the farmers of the inland states. The Romans found British wools much better suited for their clothing than the wools of Spain, because they felted more easily, and assiduously taught the Britons the art of cloth-making. Authentic proof of this was given by the discovery in Spitalfields of an

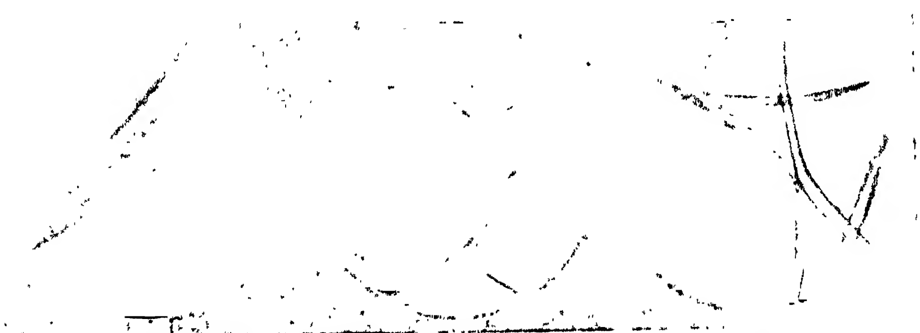
early Roman sepulchral monument erected to a soldier who is represented with a short kilt and plaid. Shattering though it may be to a proud Highland boast, we are compelled to believe that the Tartan kilt and plaid, so glorious in our military annals, originated somewhere on the banks of the Thames.

Work of a King's Daughter. After they had conquered England, the Saxons, wooed by the beauty and richness of the land, settled down to peaceable pursuits. Farmers and cattle breeders as they were, they recognised the value of the British sheep, and developed a wool trade with the weavers on the Continent. William of Normandy knew that the weavers of Rouen and the wool merchants of Caen were frequently hampered in their trade by the fluctuating restrictions imposed on wool exports by English kings. Were the two countries united, those restrictions could be abolished. That William had economic as well as political purposes in his mind when he invaded England is proved by the fact that he brought with him a company of Flemish weavers and settled them in Spitalfields soon after the momentous victory at Senlac.

An Industry of Native Growth. From this point the history of British woollen manu-



Jute Flax Silk



Hemp Cotton Wool

THE PRINCIPAL TEXTILE FIBRES AS SEEN UNDER THE MICROSCOPE

So large became the demand for English wool, that Ine, the good king of the West Saxons, about 694, thought it wise to order that "a sheep and its lamb be valued at a shilling." Another of Ine's laws prescribed "that the fleece alone be valued at two pennies—that is, at one-sixth the price of the entire sheep and lamb." King Alfred's mother is described as "spinning wool," and the great king himself did much to foster and consolidate the trade. Alfred's strong and war-like son, Edward the Elder, who began to reign in 901, "sette his sonnes to schole and his daughteris he sette to wool worke."

There can be little doubt that the high quality of English wool, and the wealth it brought, was one of the chief causes of the Norman conquest.

facture branches out into many diverse channels. It is the history of numerous different trades, each developing on its own lines. We see, however, that the industry is of native growth, no alien craft transplanted from foreign soil. Stimulated and strengthened by migrations of skilled workers from the Continent, it has been English in the main, with the English character stamped deeply into it. This is more important than at first may seem. Aptitude is inherited, and while a foreign craft may be mechanically performed, the trade which utilises familiar things grips a man, and impels him to give his whole mind to the work.

Taken by themselves, the fibres of wool, soft, silky, serrated, and curling, are natural products

of little value; he must have been a great poet who saw in them the potentialities of cloth. Labour, labour of brain and heart and hand, is the one and only "philosopher's stone" which transmutes the common things of earth into sources of human wealth and joy.

Process of Manufacture.

The task of the woollen manufacturer *is to convert wool fibres into some kind of fabric.* Alone he could not do it, for the task involves a long series of processes carried through in rapid succession by skilled workmen and complex machinery. The master of his craft knows every process, but as a practical workman he could only attend to one. The victim of this long series of operations is the wool. In the form of a fleece it is flung on the sorter's bench, and broken apart into twelve or fourteen different qualities, according to the breed or variety of sheep.

When a bag has been filled with the quality in demand, it is hurried off and flung into the steeping pans of hot water and soap, "soused," lifted out, squeezed, and thrown into the scouring vats. After being forked about among the scouring liquor and sent out of one bath into another, the last filled with clean warm water, the wool is finally dried.

Soon the scene changes, and now the wool is thrown into noisy machines; it passes through one that tears all its locks apart with fierce teeth, and into another that searches through every fibre for burrs and thorns; then it is borne onward into the grip of a machine with little spiky rollers which pinch and pu and draw, loosening the clinging hold of fibre or fibre, and, passing through a series of these machines, comes out a long soft rope. The wool has now changed its form, and at this point may be sen in one of two direc tions. It ma; either be put o the combing ma chine and prepare for being mad *into worsted,* o *it may be set on* the condenser for manufacture into woollen yarn. If destined for the condenser, the sliver, as the soft rope is called, is wound on short drums, which are hung at the end of a long machine, fitted with brush cylinders and rubber rollers. The brushes gently lead the soft slivers under the rubber rollers that roll and oscillate, forming thick threads which are wound on to large bobbins.

The Thread.

Now a *thread,* the wool goes to the spinning machines, which draw out and fine the thread.

When of the proper fineness, it is reeled into *hanks,* and is *yarn.* Meanwhile a designer has worked out a pattern, and in obedience to his plan, sections of the wool are taken, some to be bleached, some to be mordanted, reddened, blackened, purpled, or crimsoned, in the dye-house. Then all are brought back to the winders in the factory, who wind one part for weft on shuttle cops, the other on to bobbins for the warpers. The yarn is warped, dressed, wound on a weaving beam, and healded, then mounted on the loom, where it is woven into *cloth.* Though the wool has become cloth, its troubles are not over. It must go

ALL CLASSES OF WOOL.

(The figures after names indicate average length.)

1. Merino Lamb's, $2\frac{1}{4}$ in.
2. Lamb's, South American, $1\frac{1}{2}$ in.
3. Merino Greasy, super-clothing, $2\frac{1}{2}$ in.
4. Sussex Downs, 3 in.
5. Alpaca, $7\frac{1}{2}$ in.
6. Greasy Fine Botany, $3\frac{1}{4}$ in.
7. Cheviot, $4\frac{1}{2}$ in.
8. Skin or Dead Wool, 2 in.
9. Greasy Fine Crossbred (Australian), 3 in.

through the finishing processes, be *buried*, filled with soap, milled, teasled, shorn, steamed, and pressed.

Such, in outline, are the leading features of woollen cloth manufacture. There are other processes, similar in many respects, but different in others, for the making of worsted cloths, felts, carpets, and other fabrics. We shall meet with these in their proper places.

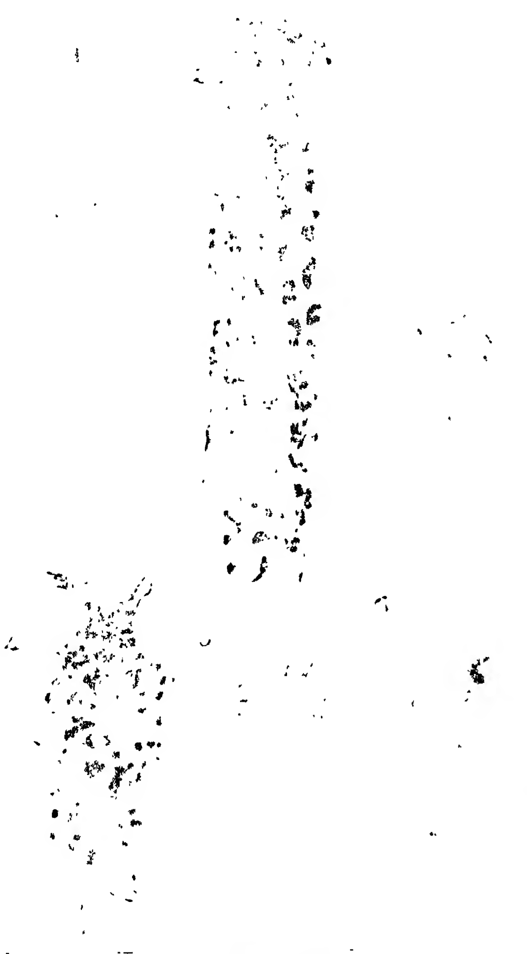
Materials. If the woollen manufacturer were allowed to operate on pure wool alone, his task would be a comparatively easy one; but modern conditions make far larger demands and require him to utilise with understanding, not only the numerous classes and varieties of wool, but also a large number of other kinds of raw materials. Nearly every textile fibre, in fact, comes into the woollen industry.

The reasons for this are various. Sometimes a cloth has to be enriched, and silk is employed: in another case, notably carpets, the warp must be a strong material, and linen forms the warp; to lighten and cheapen the fabric, cotton, noils, shoddy, mungo, and extract are mixed in.

The raw materials of the woollen manufacturer are classed under three heads:

1. ANIMAL FIBRES. Wool, hair, and silk.
2. VEGETABLE FIBRES. Cotton, flax, hemp, and jute.
3. ARTIFICIAL FIBRES. Noils, shoddy, mungo, and extract.

The two first classes are easily identified, and we shall be thoroughly familiarised with them in due course; but the artificial fibres belong to a class by themselves, and are peculiar to the woollen industry. Some description of them is, therefore, necessary here.



ALL CLASSES OF WOOL.

(The figures after names indicate average length.)

1. Lincoln Hog's, 10½ in.
2. Leicester Hog's, 12 in.
3. Yorkshire Hog's, 10 in.
4. Mohair, 8 in.
5. English Greasy Lustre, 6¼ in.
6. Irish Hog's, 8 in.

Noils. This fibre is the refuse of the combing process. Combing wools are, by implication, long, and the comb is employed to sort out those fibres not up to the standard. The noils, as the rejected fibres have been named, are otherwise good, and may be mixed in with the same class of wool for making woollen cloth, or, if broken, may be handed over to the felt-making or shoddy departments.

Shoddy. Manufacturers pleasantly name shoddy "manufactured wool." The term is speciously descriptive, for the material is made from wools which have passed through the process of manufacture. Soft worsted rags of any kind—old stockings or soft cloths made from long-stapled wools—are cleansed and torn into soft fluff in a machine resembling the willow.

The fibres are spun in the usual way and made into cheap cloths. A famous manufacturer has contended that manufactured wool or shoddy is better for making superfine broadcloths than raw wool. In general, however, shoddy is short in staple, brittle and unreliable, and must be classed as an adulterant when mixed with wool.

Mungo. This is an *inferior* shoddy, made from hard, felted, woollen cloths. The short fibres of the cloths are still further broken in the tearing process. Mungo is therefore of little

textile value; but when mixed with low-class wools, it makes cloths of fairly good wearing quality.

Extract. Extract is the lowest possible form of textile fibre. The bulk of it is obtained by consuming with sulphuric acid the cotton warp out of mixed goods or unions, as they are called. The woollen residue is extract.

No animal has a wider geographical distribution than the sheep. Protected by its woolly coat, it roams over Iceland in the north, India and Australia in the tropics, and Patagonia in the frigid south. It feeds on grasses, heaths, mosses, and the tender shoots of many trees. Lands otherwise useless will feed sheep; sheep can live anywhere except on the dry desert, or on the still more barren snowfield. Like all other animals, the sheep is modified by climate and feeding, so that the sheep of the Rocky Mountains bears little resemblance to the Cheviot. But, however much they may differ in size and superficial appearance, all true sheep give wool.

CLASSES OF WOOL

Though not more than a tithe of the sheep breeds supply wool to the world's markets, the variety of wools on the Exchange is large enough to tax the skill and experience of the most expert wool buyer. To the British markets, at London, Bradford, Leeds, Huddersfield, and elsewhere, come wools from Spain, Germany, Austria, Russia and France, in Europe; Cape Colony and Natal, in South Africa; Port Philip, Sydney, and Brisbane, in Australia; from New Zealand, India, and South America. In addition, the United Kingdom itself annually produces a clip of over 140,000,000 lb. of different classes of wool.

Russian wools, owing to the width of the territory covered by the name, comprise many varieties, from the soft curling ringlets of the Astrakhan to the short felting wool of the Iceland sheep. The chief contribution of Spain, sadly diminished of late, is derived from the famous merino sheep, the progeny of which, in Saxony, Silesia, and Australia, now produce the finest wools. The merino is a large sheep, its whole skin, from the tip of the nose to the end of the tail, being covered with a soft, fine wool, averaging from three to five inches in length. Political and social unrest have now impoverished Spain, and the breed of sheep there has deteriorated. Early in the nineteenth century, the sheep-breeders of Saxony and Silesia imported Spanish Merinos, and by careful breeding improved the stock. As a result, those provinces give names to the highest qualities of wool.

The fineness and lustre of the wools of Germany and Austria have greatly assisted woollen manufacturers to produce cloths equal to mohair and alpaca. Closely rivalling the wools of Saxony in quality, Australia sends large quantities of wool to the home markets. In 1798, Captain Macarthur, with commendable foresight, introduced a small flock of merino sheep, three rams and five ewes, and succeeded in acclimatising them, with the result that the breed spread all over the Australian continent. Despite droughts of phenomenal severity, the sheep-breeding, wool-producing industry has flourished in Australia, and in the year 1904 the Commonwealth sent to the London market wool to the amount of over 200,000,000 lb.

French wools are chiefly remarkable for their purity of colour, French wool-growers having to compete for the custom of their own dyers, the most fastidious colourists in the world.

Argentina is the largest South American exporter of wools to this country. Though equal in quality to the best British wools, the fleeces are dirty, irregular, and unreliable. Alpaca and vicuna come from Peru and Bolivia.

Cape Colony bids fair to become, in the near future, a kind of universal provider to the wool consumer. Mohair, alpaca, merino, and the native fat-tailed sheep seem equally to flourish in South Africa. At present we derive from that region about 70,000,000 lb. annually. The wools of India are crisp, deeply serrated, short, and strong, indispensable to the manufacturers of felts and carpets.

British Wools. The large variety of British sheep breeds has been, with difficulty, divided into two classes—long-woolled and short-woolled—by writers on the subject. Practical men, however, do not accept the classification implicitly. A better, though not perfectly accurate, division is given under the terms carding and combing. Carding wools are short, serrated, of good felting property, and used in the manufacture of woollen cloths. Combing wools are the raw material of the worsted manufacturer, and have fineness, length, lustre, and elasticity as their main qualities.

Lincoln, Leicester, Romney Marsh, and Blackface sheep produce the bulk of the combing wools; the Shropshire, Oxford, Hampshire, Norfolk, and South Downs, and Welsh and Shetland breeds yielding carding wools; Dorsets and Cheviots may be grouped in either class; Lincoln wool is long, lustrous, silky; Leicester, fine, elastic, lacking in softness and lustre; Blackface, long in staple, coarse in fibre, suited for heavy cloths; Cheviot wool is fine, soft, of good colour, and medium length; Dorset is weaker than Cheviot, but otherwise similar in character; Shropshire Down gives the best carding wools, clean, lustrous, flexible, and of good felting property; Norfolk ranks next, the wool being highly valued for general textile work; Oxfords and Hampshires, long-stapled, but coarse, suitable for rough woollens, carpets and flannels; South Down wool is fine, but harsh and brittle. Welsh wool is lacking in curl and fineness, but serves to make good flannels. Shetland wool, curling, but deficient in serrations, almost hair-like, makes a good knitting wool, and some hosiery manufacturers specialise with it.

These classifications profess to be no more than pointers, and as such afford the student useful guidance. But sheep farmers are constantly improving the flocks, crossing one breed with another, and importing fresh strains, so that the classifications of yesterday are unreliable to-day.

To be continued

A SHORT DICTIONARY OF THE TEXTILE TRADES

ABB—Woof; fleece skirtings.
Abbwool—Warp yarn.
Alpaca—Cloth from wool of Peruvian sheep.
Angora—Cloth from Angora goat wool.

BALE—Package of cotton, wool, or other raw fibre.
Baling—Pressing cotton or wool into small bulk.
Band—Cord of spinning spindle.
Bank—Bobbin frame.
Beam—Wooden cylinder on which warp is wound in loom.
Beaming—Winding warp on beam.
Beating—Opening and cleaning textile fibres
Bengal—A striped muslin.
Binder—Lever of shuttle-box.
Bink—Mass of cotton ready for mixing
Blind-weaving Loom—Loom with wide warp
Blower—Machine for spreading textile fibres
Bobbin—Spool headed at both ends for holding yarn.
Bobbin and Fly Frame—First machine in spinning process, see slubbing, roving, drawing, &c
Bobbin-lace—Lace made by unwinding thread from bobbins on to pins stuck in a pillow, according to pattern.
Bobbin-stand—Frame holding bobbins from which warp is formed
Bobbinet—A net lace
Bolster—Sleeve of spindle in spinning frame
Bolt—Narrow roll of cloth.
Bombazin—Fabric of mixed silk and wool
Border—Selvage.
Borders—Narrow cloths and laces.
Brattice-cloth—Heavy canvas for mine ventilators.
Breaking—Forming wool fibres in long lengths.
Breaking—Shortening flax fibres
Breast-beam—Cloth beam on a loom
Broadcloth—Fine woollen cloth over twenty-nine inches wide.
Brocade—Silk fabric ornamented with silver or gold
Brussels—Kind of lace, imitating Brussels point; carpet.
Buck—Bleaching liquor; linen in first stage of bleaching.
Buff—A strong rough felt.
Bundle—60,000 yards of flax yarn.
Buntine—Printed cotton.
Burlap—Wrapping canvas made of flax, hemp, or jute.
Burling—Picking threads and knots off cloth.
Burring—Removing foreign vegetable matters from textiles.
Burr—Waste of raw silk.

CALENDER—Smoothing and pressing cloth.
Cambric—Fine white linen cloth.
Camlet—Rough cloth of camel's hair; fabric of mixed wool, cotton, and silk, with wavy surface.
Can—Tin cylinder holding slivers.
Canton flannel—Cotton flannelette.
Card—Machine for disentangling and ranging textile fibres, lap or sliver of carded fibres.
Cards—Perforated slips of card used in the jacquard apparatus.
Cashmere—Wool of Tibet goat; a fine worsted cloth.
Chainwork—Hosiery fabric.
Checks—Pattern made by crossing warp and weft of different colours.
Chinchilla—Woollen imitation of Chinchilla fur.
Chine—Fabric woven with variegated and mixed yarns.
Chintz—Fine quality of printed calico.
Chip—Straw plait.
Cleaner—Silk brushing machine.
Clearer—Rollers in carding machine.
Clearer—Silk fixer.
Clearing—Whitening unprinted part of calico.
Clew—Thread of warp or yarn.
Clewing—Straightening warp threads.
Clip—The whole wool of a flock; the act of shearing.
Cock-a-bendy—Tool for twisting ropes by hand.
Comb—Machine for separating fibres of textiles
Comb—Hat former.
Condenser—Set of oscillating rollers for reducing the sliver
Cop—Small cylinder on which yarn is wound
Copping-rail—Bobbin rest on the throstle spinner
Cord—Fabrics with corded surface
Cording—Setting the heddles, or healds, in the loom
Cram—Close warp.
Crewel—Two-thread worsted
Cut—A length of yarn, 300 yards

DAMASK—Figured linen
Damper—Humidising or spraying machine
Devil—Rag tearing machine, fibre cleaning machine
Diagonal—Twilled woollen cloth
Diaper—Small cloths with damasked figures
Dimity—Strong cotton fabric, corded
Discharge-style—Method of calico printing
Dividing-sinkers—Apparatus on knitting machines
Doffer—Comb or cylinder at end of carding machine.
Doubles—Shoestring ribbons woven from doubled warp
Doubling—Spinning or twisting strands of yarn into one
Draught—Arrangement of the healds or heddles
Drawing—Putting the warp through the heddles
Draw-boy—Boy who pulls warp threads in harness weaving.
Drawing-frame—Machine by which textile threads are attenuated.
Drawing-roller—Fluted roller of the drawing frame
Dressing—Strengthening yarn with starchy substance
Drill—Heavy twilled cotton fabric
Drop-box—Shuttle-box automatically delivering shuttles as required.
Dunging—Removing superfluous mordant by dung.

EDGING—Narrow lace.
End—Sliver, thread, carding; worsted yard in Brussels carpet
Extract—Woollen material derived from union cloths.
Extractor—Centrifugal drying machine.

FANCY—A cylinder on the carding machine
Feed-cloth—Apron leading fibres into machinery.
Fell—End of web
Felt—Cloth formed by beating fibres together.
Fine-drawing—Sewing up faults in a weave.
Fingering—Thick worsted yarn combed out.
Finishing-card—Last carding-machine in a series.
Flannel—Soft, unshrinkable, woollen fabric.
Flax—Raw material of linen.
Fleece—Wool of one sheep.
Flyer—Double hook bent over bobbin on spinning frame.
Flyer-lathe—Horizontal beam which beats weft into warp.
Floats—Threads crossing without intersecting warp.
Floor-cloth—Textile fabric painted over.
Floss—Ravelled down off the silk cocoon.
Fly-shuttle—Shuttle mechanically driven.
Footing—Plain lace.
Frame—Head of batten in loom.
Frieze—Rough woollen cloth.
Fringe-loom—Loom on which fringes or fringed cloth is woven.
Frizz—Lift up nap of cloth.
Fulling—Beating cloth to felt threads together.
Fustian—Strong twilled cloth of mixed cotton and linen.

GALOON—Silk, woollen, or mixed braid
Gassing-frame—Machine for burning loose fluff from yarns.
Gauze—Light silk or cotton cloth
Gig-mill—Machine which roughens up the nap of cloth
Gill—Carding of flax
Gill-box—Wool-combing machine.
Gimmer—Ewe over one year old.
Gimp—Silk covered cord
Ginning—Freeing cotton wool from seeds by a machine
Glove—Hatmaker's tool, a flat piece of wood causing nap to adhere to felt
Grasscloth—Cloth made of China grass fibre
Grey Goods—Fabrics in natural colour
Gunny—Coarse jute canvas

HACKLE—Steel pin used for straightening out fibres of flax or hemp
Half-gang—Section of warp
Hank—560 yards of wool yarn, 840 yards cotton and silk
Hardening—Forming felt into hat shape
Harness—Apparatus controlling warp on loom
Hasp—Spindle
Hawser-laid—Rope of three strands of three yarn each
Heck—Guide regulating spun yarns in reeling, warping, beaming.
Heddle—Eyelets in looped cords hung vertically from transverse bars, and used to carry the warp
Heer—A length of yarn, equals two cuts.
Hurdle—Bowing bench of hat-felter
Hydro-extractor—Centrifugal drying machine

INGRAIN—Dye in the wool
Italian—Satinised cotton cloth

JACK—Pivot bar of knitting machine
Jack-sinker—Plates moving on jack to form knitting loop.
Jack frame—Sliver twister.
Jean—Twilled cotton cloth, sometimes mixed wool and cotton.
Jigger—Felting machine.

KEIR—Bleaching vat.
Kemp—Hairs among wool.
Kersey—Ribbed cloth of long staple wool
Kerseymere—Light woollen twill with oil finish.
Kidderminster—Double warp cloth carpet.
Knitting-burr—Winged wheel acting on yarn in knitting machine.
Knotting—Picking out knots in cloth.

LADE—Channel of water-power.
Lambskin—Woollen imitation of dressed lambskin.
Lap—Web of carded wool.
Lapper—Cloth folder.
Lapping—Blanket of calico-printing machine.
Lash—Thong binding warp cords of Brussels carpet.
Latch—Hinged hook of knitting-needle.

Lathe—Wooden frame driving weft into warp.
Lattice-carrier — Endless belt of wooden strips carrying cotton.
Lay—Of cotton, 120 yards; linen, 300 yards; rope, the style of laying the yarns.
Lay top—Conical block of wood kept close to the twisting point of rope yarns.
Lead-sinkers—Complement of jack-sinkers.
Lease—Band round warp sections.
Lease pins—Warp dividers.
Lease rod—Lath holding warp bands apart in loom.
Leasing—Keeping warp threads on one plane.
Leashes—Cords of the jacquard; the heddles.
Let-off—Warp beam regulator.
Levantine—Fine silk cloth.
Licker-in — Small roller working on carder between feeder rollers and main cylinder.
Lifting-bar—Holder of lifting blades of jacquard
Lifting-wires—Wires of jacquard apparatus.
Linen—Cloth made of flax or hemp
Linen-prover—Microscope
Linoleum Cloth canvas covered with prepared linseed oil
Linsey-woolsey—Cloth of mixed linen and wool
Lint—Flax thread, softened linen for bandages.
Liquor Solution of dye or mordant
Lisle—Fine lace
List Binding border of web
List Woollen flap of the ropemaker
Llama Wool of the llama.
Long-wool—Combing wool
Loom Weaving machine
Loop-cutter Blade at end of looping wires.
Looping wires Wire forming loops of tapestry carpets, velvet and plush pile
Lustre—Highly finished cloth of cotton warp and woollen weft

MACRAME lace Lace made from twine
Madder style—Printing calico with mordant.
Mangle Calendering machine
Matting Fabric made of flax, coir, jute, by plaiting or weaving
Mercerise Giving textile fibres a gloss.
Merino Wool of merino sheep
Merino Fine dress cloth made of merino wool
Mixtures Cloth made of mixed yarns
Mordant Metallic salt fixing colours
Mountings—Pattern forming apparatus of the loom
Mule Spinning frame which draws and twists rovings.
Mungo *Cloth made of fibres derived from old woollen rags*

NANKEEN Cloth made of yellow cotton.
Nap—Fine hairy surface of cloth, pile of velvet or plush.
Needle-loom—Loom in which a needle serves for shuttle.
Needle-warp—Additional warp, passed through needles set on a transverse lath
Net—Lace formed by netting
Netting—Twining two ropes into one.
Nipper—Rope-tarring gauge
Noils—Waste from combing machine

OPENING—Loosening textile fibres.
Organzine—Thrown silk.

PACK—About 240 lbs. wool
Packsheet—Coarse cotton, flax, or jute cloth covering for bales.
Packthread—A cotton or hemp twine.
Padding—Covering calico with mordant.
Pattern-box—Box delivering shuttles according to pattern.
Persian Light silk.
Persian Carpet—Carpet with linen warp and tufts of wool for weft.
Patent Axminster—Imitation Persian carpet.
Pick—A thread of weft.
Picker Fibre cleaner; shuttle driver.
Picker-peg—Wooden or leather peg that strikes the shuttle.
Piece—10 yards muslin, 28 yards calico, 26 yards linen.
Plaiding—Woollen goods of check pattern, generally heavy cloth.
Planking—Forming hat bodies.
Plough—Nap cutter.
Plucker—A kind of carding machine for combing wool.
Plush—Cotton velvet.
Ply—The number of yarns in a thread.
Point—Lace worked with the needle.
Points—Needles in a knitting machine.
Print—Calico printed.

RADDLE—Warping guide
Reed Two-sided comb of brass wire, set in the loom lathe to beat the weft into the warp
Reeding Putting the warp through the reed
Reel Core on which fibres, yarns, threads, or cloths are wound
Rep Corded fabric
Resist-style Method of calico printing
Ribbon Narrow web
Ring-spinner Spinning machine drawing and twisting thread by ring or disc
Rock Hand spinning staff
Rope Cord made of cotton, flax, hemp jute, and wire
Rovings Slivers reduced by drawing and twisting for spinner
Rug Rough woollen fabric

SARCENET Plain silk ribbon
Sateen Imitation satin
Satin Smooth, bright silk cloth
Scarf-loom Narrow loom
Scribbler—First carding machine
Scrimping bar—Regulator of the feed to a calico printing machine
Selvage Strong edging of web
Setting Placing the printed warp of tapestry carpets.
Shed Space between the upper and lower halves of the warp
Shearing Cutting the nap of fabrics even
Sheeting Common calico
Shoddy Cloth made from worsted rags.
Shot A single thread of weft.
Shroud-laid Rope made of four strands
Shuttle Wooden boat carrying the weft cop across the warp
Singeing *Removing the fluffy nap in gassing*
Size Glutinous substance for dressing yarns.
Sleave Tangled silk.
Sliver—Soft rope of fibre formed on the carding machine
Slubbing Reducing sliver to uniform size
Snick A knot.
Souring—Steeping calico in dilute solution of sulphuric acid.
Spindle—Rod axle of revolving spool, cop, or bobbin
Spindle A length of yarn of different length in different fabrics
Spinning—Drawing out fibres into thin threads.
Spoon—Automatic stop-motion of the drawing frame
Spots—Fancy spotted muslins.
Spreader—Flax carder
Staple Lock or tuft of fibre.
Stocking-frame—Knitting loom.
Stocks—Fulling or felting mill.
Stoving—Drying in hot air.
Strands—Twisted lines of which a rope is formed.
Straw plait—Material of straw hats.
Stretcher mule—Spinning frame for fine yarns.
Stretcher—Lace drying machines.
Stripping—Clearing the carder.
Stripes—Alternately coloured fabric.
Strop—Double-eyed rope for twisting strands.
Stuff—Commercial name for fabrics.
Sun hemp—Low quality hemp.
Surah—Silk.
Surat—Indian cotton of a coarse kind.
Swansdown—A fluffy cotton cloth.
Swifts—Reel for hanking yarn.

TAB—Arm of the fulling stock.
Tabby—Watered silk.
Take in—The motion of the cloth beam.
Tambour—Embroidery or fancy weaving apparatus.
Tape—Narrow fabric.
Tapestry—A light kind of carpet.
Tanty—Hindu loom.
Tartan—Woollen cloth of crossed and chequered patterns.
Tatting Making a kind of lace
Teasling—Ruffling up the nap of cloth with thistle burrs
Tenter—Loom mechanic
Tenter frame—Frame on which fabrics are stretched and dried.
Tew Pressing
Thirl Bind or tie
Thread Twisted yarn, sewing cord.
Thread frame Doubling and twisting mill
Throstle Ring spinning frame
Throwing Spinning and combining silk yarn
Thrums Weft ends and broken warp
Tow Tuft of fibre
Towelling Coarse linen cloth.
Tram Silk weft
Tufted carpet Patent Axminster
Tweed Light twilled woollen fabric.
Twill Fabric having the warp and weft twilled
Twine Turning fibres or yarns round each other
Twisting Forming one thread from several strands of yarn by twining them

UNION Cloths made from mixed yarns cotton wool, etc

VALANCE Silk fringing
Valenciennes Lace of hexagonal pattern
Veiling Fine lacy fabrics.
Velure Smoothing and lustring the silk hat
Velvet Silk pile fabric
Velveteen—Cotton imitation of velvet.
Venetian *A kind of warp raised carpet*
Vicuna *Cloth made from wool of Bolivian sheep.*

WALK-MILL Fulling mill
Warp—Threads on which the weft is woven to form cloth
Warp beam—Roller holding the warp
Warping—Winding the warp from the yarn bobbins.
Waste—Broken fibres useless for spinning
Weaving—Crossing warps by weft on a loom.
Web Fabric woven.
Weft—Thread crossing the warp.
Willow—Machine for cleaning textile fibres.
Wilton—Velvet pile carpet.
Wincey—Cloth made of cotton warp and wool weft.
Winding—Coiling yarn on a bobbin or cop.

YARN—Spun fibre.

APPLIED EDUCATION, THE UTILISATION OF KNOWLEDGE IN EVERY WALK OF LIFE

BY

ERNEST A. BRYANT, F. L. RAWSON, and HAROLD BEGBIE.

A GREAT IDEA, THE PRICELESS ASSET OF THE WORLD

By Ernest A. Bryant

THE world is ruled to-day, as it ever has been ruled, by the men of ideas. Behind the thrones of the great Powers they stand, directing the hand which nominally wields the sceptre. In the great republics the men with ideas are they whom the nations choose. In all lands where government is pure and for the greatest good of the greatest number, the high offices of State are held by the men with brains.

Lineage and academic distinction shrink to insignificance in the fires of modern competition. Were it otherwise we could not have seen the scion of a village postman upon the Papal throne; the descendant of a line of peasants at the head of the French Republic; or a man who began life on a small railway negotiating matters of the most vital importance to Russia. The possession of ideas has become a man's richest asset, provided always that he has the practical turn of mind rightly to apply them.

The Birth of an Idea. No man can command the birth of an idea. They come and they go, these will-o'-the-wisps of fancy, and no man knows whence nor whither. Their advent may be wholly without the volition of the brain in which they are born; it is for the brain to see to their retention and use. Men's minds vary in degree of receptivity and retentiveness, as one photographic plate differs from another. For one plate the merest glimpse of light enables it to record an object within its focus, no matter how swiftly that object move; the other needs long exposure and steady light before an impression can be received. Both plates are essential to the photographer's art; the one for rapid movement, the other for still life, dim interiors, and every item of detail.

So it is with men. To some, ideas come, complete in every particular, like an inspiration—a melody which shall sound throughout the world, a revolution in mechanics, in locomotion, in abstract science. Another man, the movement of whose mind no stimulus can accelerate, assimilates an idea by laborious mental process, but brings it in the end perfect to its work. So we find the broad line dividing the genius from the plodding, unwearying thinker, the poet from the cautious philosopher; the Browning from the Gray; the Macaulay from the Herbert Spencer; the Edison from the Singer; the man of a myriad schemes from the man of one grand idea, slowly and with vast effort won from nebulous gleams to coherent reality.

Ideas in History. Life runs so smoothly now, that originality, the superficial think, cannot possibly deflect its course to ways still smoother. So the superficial thought in all ages, deriding and persecuting the pioneers of change. But history teaches that the revolutionary and the visionary of to-day in science, in commerce, in politics, are apt to be found least advanced among the men of to-morrow. The discovery of the possibilities in steam accomplished a greater advance for civilisation than anything previously done for the improvement of locomotion from the beginning of time. Sir Robert Peel, on forming his first ministry, travelled from Rome to London to assume office as Prime Minister, exactly as Constantine had travelled from York to Rome to become Emperor. Each traveller had all that sails and horses could do for him, and no more. A few years afterwards the humblest steerage passenger had at his disposal the means of reaching Rome from London within a few hours. It was the result of an idea.

The basis of the idea was not new. Nigh upon two thousand years before, Hero, the mathematician of Alexandria, had designed the first steam engine. It was an idea which enabled Napoleon to throw an army—horse, foot, and

artillery—across the Alps, and, sweeping like a hurricane down upon Italy, lay her conquered at his feet. Here was another idea which had lain dormant since two hundred years before the dawn of the Christian era, when Hannibal, with horses, elephants, and 90,000 men, crossed, first the Pyrenees, and then the Alps. A new idea in naval attack gave Nelson the victory of the Nile, and enabled him to sweep the French and Spanish fleets from the sea. So fertile of resource was he that even to-day the naval critics are not agreed as to whether the victorious plan at Trafalgar, so striking and daring, was that with which he originally contemplated the battle.

Haphazard Revolution. Enough, however, of warfare. Our purpose is more pacific. There is no phase of life in which the fertile mind does not lift its master above his fellows. Sir William Harcourt and Lord Goschen would live in the history of statesmanship had they never done aught beyond their work as Chancellors of the Exchequer. Sir William Harcourt's Death Duties, although denounced at the time by those most affected, have proved one of the greatest reforms in national finance; and Lord Goschen's conversion of the National Debt was a signal achievement for one man's mind. Once accomplished, reforms such as these seem the most obvious solutions of the difficulties which disappear before them. But it is the fact which stares one in the face, so to speak, which most frequently is overlooked. Year after year surgeons practising in all the cities of Europe contrived, by operations, more or less to relieve affections of the ear. One day an accident occurred; a Viennese surgeon made too deep an incision and cut the bone. By a happy mischance a new and important operation was discovered. He seized the idea. Years of experience had failed to impress him with the obvious advantage thus forced by accident upon his notice.

Ideas are begotten, very often, of suggestion. There are suggestions everywhere for the eye which sees. Nature is still the great teacher if we can but read her lessons. What relation can there be between a tree and a lighthouse; between a leaf and a revolution in architecture? Monumental record exists to-day of a very close connection. The Eddystone Lighthouse, which has braved the fury of the waves for more than a hundred years, is modelled on the trunk of a tree. Winstanley's lighthouse had been destroyed by a storm, and Rudeyerd's by fire, when John Smeaton undertook to erect a successor. So narrow was the ledge of rock upon which to build that he determined the only course was to root his building after the manner of a tree. Just as the trunk is held in place by its roots deep down in the ground, so the foundations of the new Eddystone were sunk in the excavated rock, and fastened there by an ingenious dove-tailing. The Eddystone still stands, strong, immovable as ever, the model upon which all subsequent lighthouses in similar situations have been built.

The Crystal Palace from a Leaf. The Crystal Palace, with its light, graceful, yet strong design, we owe, not to an architect, but to a gardener with ideas—Joseph Paxton. No man in England was able to furnish plans to meet the requirements of the building for the Great Exhibition, the purpose for which the Crystal Palace was constructed. Defects spoilt the most promising. Paxton overcame the difficulties. He had found his idea in his garden. An examination of the fine plant the Victoria Regia had shown him the wonderful power of flotation possessed by its leaves, and the principle upon which this was contrived. What a plant could do, a man could imitate. The old and unsightly heavy ties and girders which architects had always been accustomed to employ were unnecessary. He showed by homely illustration the effect of his plan. A splinter of wood may be easily snapped if its ends be pushed towards each other; but a great force is required to pull the ends asunder. So iron and glass came to take the place of wood and stone, and a new system of building was introduced—by a gardener.

Brunel and the Worm. From such insignificant sources do great creations spring. In the dust of the earth, in the industry of a worm, in the colours of a soap-bubble, the great mind finds that which aids him some way further to read the writings of eternal laws. This is no mere flight of fancy. In the very dust is an exquisite story of the marvellous provisions of Nature to give shadow and tint; in the soap-bubble Newton found that which gave it a legitimate place among the most curious of optical phenomena. And the worm? It taught us sub-aqueous tunnelling. From the beginning of history the teredo or pholas, the soft white worm which lives in our harbours and the mouths of rivers, had pursued its destructive course, boring its way through the hulls of ships, eating the defences of harbours. It had even brought a whole country to the verge of ruin, when it so perforated the piles upon which Holland relied for its defence from the sea. No man had seen a virtue in the worm, none had been able to glean an idea from its wonderful work. Then there came Brunel, who, watching its operations, saw how he might construct his tunnel beneath the Thames. The worm, he learnt by close watching, encased itself in a calcareous tube of masonry as it bored its way into the timber. Here was the fountain of his engineer's idea. He set men to bore with rods into the mud from a shield, which was moved forward as they made their way, and a brick arch constructed in the rear, in exact imitation of the calcareous tube of the worm.

How a Great Breakwater was Built. So the seeing man finds his inspiration. Lessons such as these are everywhere to be gleaned by the observant. Take another instance, not less romantic. The engineers who built the mighty breakwater at Cherbourg noted with what strength common mussels cement themselves together, adhering to rocks and stones or any solid substance which happens to lie about them. Taking advantage of this knowledge, they saved themselves the trouble of extending their sub-

marine masonry indefinitely. They deposited in the sea at the proper places huge quantities of loose stones. Upon these they tipped tons of live mussels, knowing well that the shell-fish speedily would spin their string-like webs and so bind together the stones with a cement more durable than any man could make.

Paxton was not the only man of his generation who knew the mechanism of the Victoria Regia; Brunel was not the first to observe the process by which a soft, gelatinous worm made its way through oak timbers; their knowledge on these subjects was commonplace to the botanist and the naturalist. It was the application of the idea which was startling. Ideas occur to man after man in successive generations and are wasted, until there is fashioned the mind which is productive as well as assimilative. Men recognised and sorrowed over the evils of slavery, but none stretched forth a hand to help until there came a Wilberforce into the world to thunder forth "Emancipation!" Men saw and deplored the ignorance of the masses, but waited for Gladstone to remove the tax on newspapers. The hardship which the heavy cost of the carriage of letters entailed upon the poor was manifest to all, but the proposal of the penny post came like a bolt from the blue.

The Application of Ideas. How can ideas be applied? That depends largely upon the circumstances of the individual and the nature of his scheme. There never was a better time than now, when greater scope was afforded for the carrying out of new projects. "The men for whom we look now with a view to possible partnerships are no longer those with capital," a prominent member of the House of Commons said to the writer. "We must have men with ideas capable of adequate expression in practical production." One man, a working plumber in a Kentish village, devotes his leisure at nights, and the scanty holidays granted him, to materialising ideas which occur to him in odd moments during his work. A year of nights he sacrificed to the fashioning of an appliance for soldering—a tiny mechanism which he carries in his waistcoat pocket—lamp and blowpipe combined, which enable him to dispense with the cumbersome brazier and melting-pot. Such a man with increased opportunities might prove a second Nasmyth, and give us a contrivance as important as the hammer with which the name of that genius is associated. The villager's inventions are his voluntary creations: Nasmyth invented his Titanic hammer in response to the appeal of a man who could not otherwise get a forge hammer capable of producing the shaft which he needed.

As a rule, however, inspiration is an unwilling and unstable guest; it must be seized at once, before it may be too late. Coleridge dreamed his "Kubla Khan," and wrote in his waking moments the precious stanzas which he remembered. John Bright composed all his speeches in bed. Most of us, however, must look to periods of great mental alertness for the coming and thinking-out of ideas. And when they dawn upon our horizon, they should promptly be noted down.

An Industry in a Village Stream. There may be value in the flimsiest notion. A man thinks of a metal tip for boots, and makes a fortune from it; another applies a piece of rubber to the end of a pencil. A third compounds a decoction which, smeared upon windows, prevents their "steaming" in cold weather. Another, of scientific bent, notes that a mineral refuse, thrown away as valueless, emits a strong odour when in contact with water, and the result is acetylene gas and all that that may yet mean as an illuminant. A certain stone yields its secret to a person who by the proper process converts it into an enamel for making earthenware and china non-porous. The sands of the sea become an asset to him who discovers their use for the making of incandescent mantles. A trickling stream of mineral oil in a Derbyshire mining village was found by Lord Playfair to contain paraffin, and from his recognition of its worth sprang up the gigantic industry which has made fortunes in America such as the world before had never known. Every invention opens out fresh fields for other inventions, and the examples we have seen may stimulate thought in directions in which advance may still be made. Man sails the air and sails the seas; and hastens with the speed of the bird upon dry land. But in each phase of travel he is anxious still to do better. The electric train supersedes the steam-engine. The turbine steamer ousts the older form, just as the screw propeller gained the day against the paddle-wheel. Electricity and the motor claim the sphere of the horse for individual travel by road.

The Old World and the New. These are among the ideas newly utilised. The men in whose brains they took shape perform more notable service for mankind than the greatest general who ever slew a rival's forces. The compositor who sets up the type for the Bible, and the machinist who prints the pages, are greater forces for good than the wisest of the ancients. Those wise men of old, in the dim light which preceded the glow of learning whose glorious dawn our own day was to witness, had their splendid and noble ideas; ideas which live in architecture at which the world still marvels and cannot emulate. With their manual labour and their implements of which the world has lost count, they fashioned their wonderful Sphinx, which, in spite of all that has since been achieved, remains the greatest stone monument in the world. Their enamels have outlived the shells and rockeries of which they were but the veneer.

But the modern idea brings mightier things to pass than ever those wise men of the East could dream. We bridge rivers and straits and gorges which would have been impassable to them. We send flotillas of mighty ships where they had not a waterway. We print in an hour fifty thousand papers, one copy of which it would have taken them a lifetime to write. We navigate seas which were to them unknown; and we race at sixty miles an hour over lands whose existence was to them unimaginable.

CIVIL SERVICE

A GUIDE TO EVERY BRANCH OF PUBLIC SERVICE IN THE BRITISH EMPIRE

DEALING WITH

MANY THOUSANDS OF POSTS IN THE MUNICIPAL, NATIONAL, AND COLONIAL SERVICES

FOR

Clerks	Tramway Managers	Solicitors	Electricians
Engineers	Poor Law Officers	Surveyors	Draughtsmen
Accountants	Officers of Health	Interpreters	Telephonists
Architects	Revenue Officers	Inspectors	Telegraphists
Chemists	Post Office Officials	Attachés	Police Officers
Firemen	King's Messengers	Ambassadors	Prison Officials

WITH ALL ESSENTIAL INFORMATION CONCERNING THEM, GATHERED FROM OFFICIAL SOURCES

BY

ERNEST A. CARR, of H.M. Civil Service

THE GREAT ORGANISING ARMY OF THE NATION

By Ernest A. Carr

ENERGETIC, capable, ambitious young men and women whatever their training or social station who are in quest of a life work that offers interesting duties, liberal rewards, and a wide scope for their abilities, will be wise to consider carefully the claims of our Civil Service as a career.

The expression "Civil Service" is technically used sometimes to denote only the staffs of Government offices, but by right of origin the word "civil" means "pertaining to the citizens and the State." It is in this wider and more natural sense that we use it here. The "fighting services," as a matter of convenient arrangement, are separately dealt with elsewhere (see ARMY and NAVY), and with purely honorary posts our readers are naturally not concerned. Excluding these divisions, the term Civil Servant means for us every salaried, non-combatant officer engaged in the administration of public interests, whether strictly local or affecting the whole Empire.

A Civil Army. It is clear that a huge variety of posts, and of public bodies, is included in this definition. The officials of the smallest District Council or Board of Guardians are Civil Servants, no less than the First Lord of the Treasury or the Secretary of State. From the village lamplighter or the park policeman to our ambassador at St. Petersburg, from the political agent in some half barbarous Indian state to the telegraph messenger in Fleet Street, runs the linked band of public servants by whose united efforts the great business of the British Empire is carried on.

The numbers of this civilian army, its diversities of status, work and pay, defy calculation. In London alone its members form two army corps—10,000 more men than stood in the ranks of the Allies at Waterloo. Every industrial centre has its regiment of public servants, each small town its picket, each village at least a sentry; while lonely outposts keep watch in every corner of the globe where British rule holds sway.

Within these wide limits is room for all grades of education and all varieties of gifts. The learned, scientific, and technical professions are represented by thousands of well-remunerated posts. Clerks and bookkeepers of every rank form, as it were, the main infantry force. The practical expert and trained mechanic find in the Civil Service a ready market for their skill, and there are countless intermediate, special and minor posts besides. To analyse and classify this medley of appointments is the business of the articles that follow; our concern for the moment is with the claims of the service as a whole.

Attractions of the Service. If a popular vote were taken as to what constitutes a satisfactory calling, the first essentials agreed upon would probably be that the work should be well paid, permanent, and with some security of tenure; free from offensive or unduly arduous conditions, and offering advancement in proportion to merit and experience, with scope for personality.

Widely as the conditions of employment vary within the huge and complex machine of the Civil Service, it will certainly be found, when tried by such commonsense standards of value as these, to compare favourably with other callings. It cannot, in the nature of things, offer the fabulous incomes of our foremost singers and actors, or the first flight of "counsel learned in the law." The man whose superlative talents demand a five-figure salary should avoid the public service, unless he is within easy reach of the Woolsack. More modest ambitions, however, may secure incomes in the Civil Service averaging distinctly higher than in the unofficial world. The "sweating" employer has no counterpart in the Civil Service, which aims at securing efficiency by selecting its officials with care and paying them well. Public officers, as a class, are liberally though not extravagantly remunerated, with salaries progressing either by regular increments or according to personal merit. Generally these two systems are employed in combination.

Permanence and Security. The permanence and security of Civil Service posts are two of its most attractive features. Their

holders, unlike many private employees, cannot be dismissed save for serious misconduct or default; and, except in the Government workshops and similar fields of employment, their earnings are unaffected by "bad times." When, as occasionally happens, the remodelling of a department leaves no room for a former member of the staff, he is usually transferred elsewhere; or, should the change compel him to resign, he is liberally compensated for his loss of office. But such incidents are rare. The public official with a good record is normally secure for life.

Work Well Paid For. Nor need he be apprehensive of overwork. The day of "snug sinecures" is past, and Civil Servants must give a reasonable equivalent for their salaries. But the practice is to maintain a staff fully adequate for ordinary needs, and to reward with special grants or increase of salary any pressure of extra work which cannot be avoided.

These "perquisites" are sometimes of great value. An official acquaintance of the writer's, for instance, supplements his salary of £400 to the extent of £80 a year by occasional translations of office documents; another, whose salary is £225, recently earned £70 in six months by special evening duty. Almost the whole clerical staff of one busy Government office draws "extra duty pay" every year, varying from £30 to £100, according to rank. In municipal employment the rewards for special services are more liberal still. For extra work in connection with the electrification of a borough tramway system, an engineer received not long ago an honorarium of £200; and for a like reason the engineer to another corporation was granted a special payment of £750. Extra work among Civil Servants is welcomed rather than shunned.

Promotion. The question of promotion is complex, dependent on varying conditions. Chances of advancement vary greatly in different offices and in the several grades, but are distinctly favourable on the whole. The Government service, it is true, is hampered still by its traditions, and, while professedly adopting the principle of advancement by merit, it continues to attach too much importance to seniority, and this practice tends to make promotion slower. But the law of seniority is daily disregarded in favour of men of special ability, and is tempered, besides, by the regular increments which automatically raise each official to the maximum salary of his class. In the local services, more frankly modern and democratic, efficiency is the decisive factor, and the scope for a man of energy and capacity is almost unrestricted. The highest commands in this great civic army, as in the armies of the young French Republic, are open to any man in the ranks who can give proof of his strength.

Merely noting in a word the liberal provisions of the Service as to sick pay, leave and pensions, and reserving their detailed discussion, let us turn to consider other attractions which are not to be measured by any commercial scale. Foremost among them must be reckoned, by all who have a thought beyond money, the dignity and usefulness of the public service. This dignity is a quality quite other than the self-importance of officialdom. To take a share, however modest, in the government of the State is a distinction and a privilege. To work for the public weal, to place one's abilities, whether great or small, at the service of no less a master than the City or the State—here is surely a prospect which appeals even to the most practical and humdrum of minds.

Outdoor Life. That the Civil Service is a "noun of multitude," comprehensive enough to furnish congenial employment for almost all tastes and temperaments, will be evident from what has been said. Lovers of an active outdoor life may find their opportunity, according to ability and training, in the foreign, Indian, or revenue branches, or on the non-combatant staff of the Navy. The studious mind will turn towards the higher legal or administrative posts, the man of figures to municipal accountancy and finance, Exchequer estimates, or Government auditing. Science is given scope at our museums, in the service of the public health, and at technical colleges, while its industrial branches are represented by dockyards and telegraphs, by borough engineering and a hundred other activities. The list of special positions for men of particular aptitudes is not easily exhausted.

How are the posts in this great army to be gained? To answer this question clearly and fully, to show how vacancies are filled, what qualifications are needed for each rank, and how such qualifications are best attained, is a task even more essential than that of classifying the great mass of public appointments. To combine these two tasks is the object of this course, the purpose of which is to show, on the one hand, the character and value of every Civil Service post, whether high or low; and to explain, on the other, precisely how each post may be won. The work being primarily addressed to students and prospective candidates for the Public Service, special regard will be paid to such matters as educational standards, professional and other training, competitive tests, examination subjects, and other questions of direct and practical importance.

The Three Great Divisions. For the purpose of a detailed investigation such as this, the great subject of the Civil Service is best divided into three main sections, each of which will be separately considered. We may summarise them as the municipal, national, and Imperial branches of the Service.

The first is a wide and important division, comprising all appointments controlled by the local authorities—whose name is legion—and remunerated from public funds raised for local purposes. Officers of the county and borough councils, of district boards and Poor Law Guardians, of quaint associations like Trinity House, rich and powerful bodies like the City Corporation, and countless minor councils unknown to fame, all fall within this expansive section. The National Civil Service comprises the Government departments, great and small, whose salaries are annually voted in Parliament or paid from State revenues; and, lastly, in the

section devoted to the Civil Service of the Empire, we shall review the various classes of appointment, both municipal and under direct State control, in our colonies and possessions overseas.

The triple series will thus form in conjunction a complete practical guide to the vast field of the British and Colonial Civil Service—a task never before essayed.

THE MUNICIPAL CIVIL SERVICE

The age we live in, witness of so many splendid achievements, has seen nothing more characteristic or more startling than the rapid growth of local government. Scarcely a generation ago this branch of the Civil Service was administered partly by a privileged class with no direct responsibilities to the public, partly by undistinguished local caucuses without any special qualifications for their work. Such a system was naturally regarded by the public with an indifference not wholly free from suspicion. It was widely assumed, sometimes with justice, that public funds in such hands were apt to be wasted, and public interests either neglected through incompetence or sacrificed to private ends. Men of high aims were chary of associating themselves with a service that was "suspect"; shrewd business spirits declined to devote their energies to discussions on the policy of the parish pump.

A few years have sufficed to change completely this condition of things, in part by the agency of legislative reform, but mainly through the development of a sound civic spirit. Side by side with the expansion of the Imperial idea has sprung up a civic patriotism akin to that of the early Greek states. We have learnt to recognise the essential dignity of local administration. Social students and earnest workers of the best type, seeing in it an intensely practical ideal of service, have devoted themselves with splendid ardour to the task; and the municipal system, as a whole, has responded by a degree of activity and efficiency before unknown. Popular confidence in the local authorities has grown amazingly, and has found expression in numerous statutes consolidating and re-modelling their constitution, and greatly amplifying their powers in many directions.

Creation of the Municipal Service. Without wearying the reader with a long list of the Acts of Parliament that have created the modern Municipal Service, we may briefly refer to the foremost among them. The first great measure of this kind, since the days of the Reform Acts, was the Municipal Corporations Act of 1882. This statute fixed the town council in its present form as an elective body of aldermen and councillors headed by the mayor; it defined the powers of the council as to enforcing sanitary laws, lighting the town, and forming a borough police force; and provided for the expenses of administration by the levy of a borough rate. Six years later followed the Local Government Act of 1888—the greatest of the series of reformative statutes, and the creator of the county councils. It was a revolutionary and democratic measure, sweeping away a mass of crusted traditions and abuses, and transferring to the new authorities all duties relating to local government performed until then by justices in quarter sessions. Thus, at one stroke, the control of county finance, rating and assessment, county buildings and lunatic asylums, the registration and polling of parliamentary electors, the maintenance of highways, the prevention of river pollution, and a host of minor powers, were placed in the hands of councils chosen by the county electors.

It was a bold enterprise, and many were the dismal forecasts it evoked. But it was in essence an extension of the policy already developed by the Municipal Corporations Act—the policy of entrusting district administration to an elected body instead of a privileged class. The wisdom of that policy has been amply justified by the event, and particularly by the remarkable stimulus it gave to the country's interest in its own internal affairs. This growing attention to the claims of local government has proved a guarantee of increased efficiency and integrity in the Municipal Service, and has greatly helped to raise the dignity of the Service in public regard.

A later Local Government Act (1894) completed the system of deriving the authority of every local body from the electors. Many measures, both before and since, have added to the activities of such bodies; but the only enactments calling for comment are the Education Acts of 1902 and 1903. They have enormously extended the powers and duties of local authorities in England and Wales by making the council of every county and county borough the education authority for its own area.

The Modern Municipal System. Such are the measures chiefly responsible for the evolution of our municipal organisation of to-day. The system, as a whole, is characterised by bold and effective and public-spirited administration. Its methods are businesslike, scientific and modern, its activities of so wide a range as almost to defy description. In its hands are placed, besides the duties already named, the cleansing and improvements of our streets, the maintenance of water supplies and sewage systems, the protection of the public from fire, the relief of the poor, and innumerable other responsibilities affecting the health and comfort and material welfare of the people. The importance of these functions is literally beyond estimate. Some idea of their extent may be gathered from the fact that local bodies administer every year an income of over a hundred and twenty millions sterling. And as an instance of their bold and successful business methods, it may be added that the net profits from municipal waterworks, gas and electric lighting, and tramways, during the last recorded year amounted to £700,000.

It is only fitting that the responsible men in charge of such enormous and often profitable undertakings should be handsomely paid. Local bodies are ready nowadays to recognise the right of the labourer to his hire; and, instead of a penny-wise policy, they adopt the sounder

economy of employing in each department the best men available, and of paying adequately for their services. The effect of this principle is to quicken the advancement of the capable, and open the gates of a lucrative career to any young man of brains and energy. Napoleon's dictum that every soldier in his armies carried a field marshal's bâton in his knapsack might be justly applied to the official rank and file under our modern municipal system.

Rapid Promotion. A striking instance of rapid promotion in a municipal career is that of the present Clerk to the London County Council. Entering in a subordinate capacity, Mr. G. Laurence Gomme was early advanced to the rank of Statistical Officer at £800 a year; and thence, after some years, by a single stride, to the most responsible position of Clerk of the Council, with a yearly salary of £2,000.

There is another aspect of municipal employment which is particularly noteworthy. Enormously as the system of local government has developed, it is destined to still greater expansion in the near future. Many students of present day tendencies aver that this movement is as yet in its infancy. Whether this is an exaggerated view of its future or not, we cannot fail to realise that the Municipal Civil Service has not reached its full dimensions. It has a great future, not only of to-morrow, but of many to-morrows. To enter it now, in its crescent youth, is to seize one's chance of rising with the rising tide. The growth of a department brings advancement automatically, as it were, to those members of the staff who are worth their salt, as well as furnishing special openings of many kinds.

World's Greatest Local Authority. We may readily illustrate this by reference to the last five years' records of that type and model of administrative efficiency, the controlling body for London. In this interval its activities, and consequently its staff, have developed considerably. Disregarding all promotions, we find that the salaries in respect of the self-same posts have made substantial advances. Thus the Valuer to the L.C.C. receives another £500 a year, the Chief Officer of Tramways a like advance, the Chemist £1,100 in lieu of £800, and the Comptroller's salary has risen from £1,150 to £2,000—all this within five years. Such instances will be many times recurrent in the next decade, and shrewd men will find, meanwhile, in the Municipal Service, that tide in their affairs which, taken at the flood, leads on to fortune.

Not every local authority, of course, can offer adequate careers to its employees. It is true that there is hardly a fair-sized village in the kingdom which does not afford some opening for ability, but the scope of such employment is necessarily very restricted. Only amid the intricacies and responsibilities of administering the affairs of a great town, or a county, can the best men find the best work. Hence there is a steady current of transfers from lesser to more important municipal offices, up to the foremost industrial centres, with London and Glasgow at their head.

A Typical Career. A typical career in this respect is that of Captain Nott Bower, the Chief Commissioner of Police for the City of London. After serving in the Royal Irish Constabulary, he became Chief Constable of Leeds, and next held the important post of Head Constable of the Liverpool police, with emoluments estimated at about £800 a year. Having acquired a high reputation as head of a fine and efficient force, he was next elected to the very responsible appointment he now holds, with a salary of £1,250 a year. His branch of the Municipal Service has but one higher post—the Commissionership of the Metropolitan Police Force, at £2,500 a year.

The system of promotion by transference, illustrated by Captain Nott Bower's record, is so general throughout the Municipal Service as to afford the widest possible field for capable men. Minor and provincial districts are thus a training ground from which leading boroughs and counties recruit their staffs. The best posts in the service to-day are held, with few exceptions, by men who have graduated in smaller offices, and have been translated for distinguished service.

A glance at a typical municipal office in full swing may help us to realise more fully the work of modern local government. We will select the headquarters of a borough of average importance, without any of the duties relative to county administration which occupy so many of the leading towns.

The Municipal Hive. As we traverse the various departments of the hive of municipal industry, the impression is one of bewilderment at the diverse activities of its workers. The town clerk and his special staff are busy, for several committees of the council are sitting, and each involves, not merely the attendance of a committee clerk to report proceedings, but much subsequent clerical work in carrying out the committee's directions. As from eight to a dozen such meetings are held in every week of the year, complex questions involving serious interests coming before them all, it may be guessed that the amount of detailed business necessitated is enormous.

In the surveyors' department, one of its professional heads is occupied, with a large staff of assistants and draughtsmen, in considering applications and plans for laying out or draining new roads, and contractors' tenders and accounts for road repairs; or in preparing drawings, specifications and estimates of various kinds required in connection with the upkeep of highways. Another chief surveyor is engaged in conference with the municipal solicitor over some knotty point of combined drainage or the charges for a new street. Meantime the outdoor officers, in various quarters of the town, are inspecting sewage works or the watering and scavenging of the roads.

The rating branch, with its staff of collectors and clerks and its multifarious duties of scheduling property, framing assessments, and collecting the borough rate, need not detain us long. Nor shall we linger among the books of the treasurer and the accountancy officials.

Officers of Public Health. More interesting, as well as more important, is the work of the officers of the Public Health, under the control of the Medical Officer. That officer himself we may find examining diseased meat or unsound fruit seized in the market by his vigilant inspectors. More probably he is making the round of his district—here pausing to watch the tell-tale test of the smoke rocket applied to a faulty drain, there visiting a bake-house reported to be insanitary, or elsewhere investigating a case of infectious disease. His force of sanitary inspectors is busy hunting down dirt and contagion as police officers hunt down crime. One of them is supervising, perhaps, the removal of a scarlet fever patient to an isolation ward and the disinfection of the sick-room; another is in the factory quarter, on the look out for smoky chimneys, or paying a surprise visit to a "sweating" tailor, whose workshop is overcrowded and badly ventilated. A third is preparing his report to the Health Committee against the obdurate owner of an insanitary laundry, where the water lies in pools on the uneven flooring and soaks the feet of ill-shod workers. Against these and a hundred such evils—damp walls and leaky roofs, faulty cisterns and contaminated water supplies, against underground dwellings, noxious trades and every other form of nuisance—the little band of sanitary inspectors wages unremitting warfare for the common weal.

A Complex Service. Near at hand is the laboratory of the Public Analyst—a Civil Servant like the rest. Here come the suspected samples of food or medicine, to be shredded, heated, stained, evaporated, and tested in every way known to science, for signs of adulteration. The procuring of these specimens is the mission of a special officer of the borough, and many are the wiles he must adopt to be successful. If the samples prove impure a prosecution follows.

Should the borough possess its own gas works, these will employ another staff under a skilled engineer. But if it has a progressive council, abreast of the times, it will boast of municipal electricity instead. At the generating station and workshops we find a number of technical experts, from the trained electrical engineers-in-charge to the mechanics who repair street wires and lamps. The current may be employed also for electric traction, many of the provincial boroughs owning electric tramways, which are run for low fares at a handsome profit. In that case the municipal corps will be augmented by a company or so of tram drivers and conductors, regulators, and roadmen.

The list is far from being exhausted, but we need pursue our quest no further. Without lingering over such minor outposts as the public libraries, baths, and washhouses, or at that valuable device, the dust destructor, we may conclude our survey at this point. To form any idea of the extent of the Municipal Service as a whole, however, we must include, in addition to the activities of boroughs and lesser authorities, the important duties already mentioned as vested in the county councils, and the administration of the Poor Law. All these are embraced in our definition of the Municipal Civil Service.

How Appointments are made. It is not too much to say that within this varied, complex and far-reaching system almost every career can be pursued at least as effectively as for private ends. The scope afforded is generally greater, while the added distinction and usefulness of public work admit of no denial, and must appeal to all who recognise that civic patriotism is not less a virtue and a duty because it goes clad in colours less conspicuous than khaki and scarlet.

No uniform practice exists for filling vacancies in the Service. Subject, in certain instances, to the Local Government Board's approval of the selected candidate, the authority concerned is free to adopt what method it deems best. Substantially, however, the mode employed is one of three. Either the appointment is advertised and applications invited, or an existing member of the staff is promoted, or the vacancy is filled from outside on the recommendation of the responsible official in whose department it occurs.

Of the three methods the first, which is based on the sound democratic principle of "a fair field and no favour," is coming more and more into vogue for responsible positions, and for junior appointments which cannot be filled by promotion. It is certainly best, not only for candidates, but for the Service itself, that posts should be filled by honourable competition, and not by backstairs influence. Where this method is adopted, the practice is to advertise, naming the salary offered and inviting competitors to state their qualifications and experience and to forward testimonials—usually three or four. From the applications received, a committee selects probably half a dozen of the most promising, and these candidates are invited to attend in person before the council itself. The final choice is then made from among them, by vote if necessary.

The Reward of Merit. The second method, of promoting a member of the existing staff, is widely adopted for filling posts of average or minor grade. It constitutes an attractive feature of municipal employment, and by assuring merit of its reward is a powerful stimulus to efficiency. But when a specially qualified official is needed, or the responsible head of a department, it is found that, as a rule, better results are obtained by selecting candidates from a less restricted field. From the point of view of able, energetic young officers, bent on making a career for themselves, the last-named mode has this great advantage, that it saves them often from the tedious fate of finding their road to advancement blocked by some immovable "fixture" in the senior rank. There is no need to enlarge on the last of these three specified ways of filling vacancies, as it is usually adopted only when the appointment to be made is not attractive enough to create competition.

Candidates must mainly rely on entering the Municipal Service by the first gate. Once in it, they may win their spurs either in the same fashion or by promotion.

MILITARY ENGINEERING AND THE MANUFACTURE OF ARMS, AMMUNITION, AND EXPLOSIVES

CONDUCTED BY

JOSEPH G. HORNER, Practical Engineer for thirty years; Associate Member of the Institution of Mechanical Engineers; Author of many Standard Books on Workshop Practice

F. L. RAWSON, Associate Member of the Institution of Mechanical Engineers

J. W. WAINWRIGHT, Associate Member of the Institution of Civil Engineers

MECHANICAL ENGINEERING AS A PROFESSION

By Joseph G. Horner

TO become an engineer means a good deal of hard preliminary work. Its exacting character is due to the fact that the work is of a twofold character, and that it is extremely comprehensive. It is both physical and mental, involving long hours of exhausting labour in the factory, followed by study at night. There is no royal road in this pursuit, and there is no shirking hard facts. An engineer stands no chance of success unless he has a sound mind in a sound body, and the love of work. This will be sufficiently clear after we have outlined the course which has to be pursued.

The Scope of Engineering. The man who practises one of the various crafts which are included in the group of trades comprehended in mechanical engineering, is not, if his knowledge is bounded by that craft alone, an engineer. He is a pattern-maker, or a boiler-maker, or a turner, or fitter, etc. The craftsman on whom devolves the task of the final erection and completion of an engine, or piece of mechanism ready for operation, is in some sense entitled to be regarded as such, but that is not nearly all which is included in the term engineering. For, unless a man understands intelligently the practice of *all* the departments which are comprised in an engineers' works, with the scientific basis that underlies them all, and the economies of manufacturing production, he is not an engineer in the fullest sense, and is not qualified to become a manager or leader of a great works, or a designer of mechanisms. How much and what varied knowledge is involved in the principles and practice of the several trades will be seen as we progress. For the present let us take a general survey of the method by which the profession is entered.

With comparatively few exceptions, pupilage is the gateway into the broad field of engineering. The exceptions are those in which a workman by force of character and skill has broken away from his narrow trade, and qualified himself for a higher and broader sphere of action. It is with a view to lend a helping hand to men of this class who desire to "break their birth's invidious bar" that the SELF-EDUCATOR has been projected.

The First Thing to Do. If a youth intends to follow the profession of a mechanical engineer, his first course is to seek a firm with which to be articled. Some would prefer the easier, more gentlemanly, technical school. But this is a mistaken view. The school in its place, by all means; but the factory comes first. Those who advocate taking the school first point out the advantages of receiving a grounding in the principles of mechanics before going into the shops. But the elements of the sciences will already have been gathered at school and college, and it is best to enter on the field of practical work at an early date, and study theoretical science consecutively therewith.

If the decision is made to take the shops first, the choice of a firm is difficult. Many matters have to be considered. Avoid firms that advertise for pupils. The good firms always

have the names of youths on their books, who have to wait their turn for admission, in some cases for two or three years.

The selection may often have to be determined by the special branch of engineering which it is the intention to pursue in after life. This applies to those who know beforehand that they must be specialists in certain lines, as, say, in loco work, marine work, hydraulic machinery, machine tools, etc., though in any case there is much to be said in favour of some general training as a broad basis on which to rear the specialised work.

Articled Pupils. Engineering firms take pupils for terms of years ranging usually from three to five, and charge premiums from £50 to £100 a year. Occasionally, though seldom, a small wage is paid to the pupils. In return for this premium few firms undertake to impart any precise instructions. It is sufficient that lads have permission to enter and pass through the several shops, taking a part in the work that is carried on therein, and observing and noting as much as they are capable of assimilating. Excepting that they must be amenable to discipline, and to the general rules and regulations of the works, they are at liberty to occupy their time in all the shops, to put questions, make sketches and notes, handle tools, observe tests, work strenuously, or be as idle as they choose. The opportunity is there; it rests with themselves whether they shall gather golden grain, or neglect and lose the great opportunities afforded.

When a youth goes into the factory, certain lengths of time are generally apportioned to be passed in the different departments, a few months in one, a year in another, and so on, these arrangements being matters for individual settlement with the firm. The drawing office, pattern shop, and machine and erecting shops generally absorb the largest periods of time. Often some of the shops are omitted from the course, especially the foundry and smithy, occasional visits only being made to those. The period of pupilage is not long when divided up thus.

The Pupil in the Shops. Youths when in the shops are expected to dress in overalls and work like the trade apprentices and men, and to be subjected to the authority of the foremen. They undertake simple pieces of work, and often acquire considerable dexterity in the practice of the trades. But this alone is not the ultimate object of their labours, which should be to understand well what is involved in the practice of *all* the shops, rather than to become a skilful craftsman in any. Such knowledge is essential to the skilful conduct of a factory; mere handicraft is not. In this respect the training of the pupil differs from that of the apprentice to a single trade.

The work of the pupil in the shops is only one section of that which he has to undertake. He must study constantly as well. Study and work cannot be dissociated. Neither may study be allowed to become a barren field; it must be utilitarian, having a direct bearing on daily practice.

School *versus* Shop Training. Here the vexed question of technical school *versus* shop training arises. It is a pity that so much barren discussion should have arisen round this. No man can become a safe mechanical engineer unless he has had a preponderating experience in the shops. He must be a shop man first and foremost, and his technical training must be subsidiary thereto—an aid, but not in any degree a substitute. Most engineers would be better for more theoretical training, but the difficulty and danger lies in exaggerating its importance. How to strike the happy mean is not easy. We hold that the sandwich system—periods of shop work and study alternating—produces the best engineers, men who are neither too wedded to theory on the one hand, nor to rule of thumb practice on the other. Summer in the shops and winter in the colleges seems the ideal system. Or the day in the shops, and the evenings of winter in the schools—only that this makes great demands on the student's strength, and affords too little time for extensive study.

In the college one is apt to develop a "set" in favour of theory, and very much is learned which has to be modified when brought later to the test of practice. All the great engineers, living and dead, have been practical men first, and students afterwards. One's early practical training ever afterwards prevents the too great leaning on theory, and the waste of time, which is money in the shops, spent in arriving at results which practical men reach by short but safe cuts. The writer has strong views on this matter.

The Best Thing to Do. In reference to the selection of a shop being controlled by the special branch of engineering practice which it is intended to pursue in after life, there is some basis for this idea, but not so much as many might think. The very best early training for most men is to be found in a shop which deals more in general engineering and in repairs than in any single speciality. Special knowledge can be readily gathered after having been well grounded in general practice. To be brought up in a groove is not conducive to subsequent expansion and development. The fathers of engineering laid the foundations of their knowledge on a broad basis. Unfortunately for the pupil, the general shops are becoming scarce, because the manufacture of specialities pays better, but there are many firms still in which one can gain acquaintance with a varied and extensive practice. The alternative is to divide a few years among different firms. It is, however, possible that in certain cases it may be judicious to enter a special shop. For example, if a pupil has such influence in certain quarters that it is settled he is to pursue one branch of engineering only, perhaps conduct or hold a responsible position in a certain business, then it may be well to receive a training in a firm doing the same kind of work in another locality.

Engineering Departments and Allied Subjects. The prospects of the profession are not too alluring; unless a man's heart is in his work he may do better as a retail tradesman. Unless he has either capital or influence, long years of hard work must be the price of an ultimate moderate competency. But the work is good, and health and joy in one's pursuit are to be preferred to wealth alone. But there are prizes in the profession, and they come in many forms - in the form of a share in the business, as principal, or partner; the management of large works; consultative work, if a man has a speciality; posts under governments and on railways; agencies in growing countries; and professorships.

The main departments into which mechanical engineering is divided are:

AUTOMOBILES	MACHINERY AND TOOLS
BEARINGS AND SHAFTING	MINING PLANT
BOILERS	PULLEYS, GEARS
BRIDGES, DREDGERS	PUMPS, TURBINES
CONVEYING DEVICES	TRANSPORTING DEVICES
CRANES, HAMMERS	WATER WHEELS
ENGINES, FURNACES	WELL BORING PLANT
HYDRAULIC MACHINES	WINDMILLS

The scientific subjects of which a mechanical engineer should have a working knowledge embrace:

ALGEBRA	MATERIALS
APPLIED MECHANICS	MENSURATION
CHEMISTRY	MINERALOGY
ELECTRICITY	MINING
EUCLID	PHYSICS
FUELS AND HEAT	PLANE TRIGONOMETRY
GEOMETRY	PNEUMATICS
LIGHT AND SOUND	POWER OF ALL KINDS
MAGNETISM	STEAM AND WATER

APPLIED MECHANICS

The study of pure mechanical physics alone is an insufficient equipment for the designer of actual mechanisms and machines. Mathematics are faultless in the realms of pure theory, but apply them without modification to the stability of structures and the movements of machines, and they become misleading. Theory is good, inasmuch as it enables the student to think out first principles, but it must be supplemented by the corrective experiences derived from practice.

We therefore find that the whole history of mechanical practice is one of experimenting, recording, and collecting, with a view to the establishment of safe rules for guidance. The experimentalist adopts the Baconian method of reasoning from facts. He does not despise theory, he simply refuses to take it as an absolute guide. In fact, he often adopts some working theory to start with. With hardly an exception, the successful motors and machines of the present are evolutions, and not creations. Little by little they have been developed through countless imperfections and failures. The papers of the technical societies are nearly all records of experiment and experience. The so-called empirical formulæ embody the same, inasmuch as the "constant," or the "coefficient"—the central factor—is a mean derived from myriads of cases in practice. The value of hundreds of formulæ lies in this little quantity. No engineer would dare to apportion thicknesses or stresses by mathematical theories alone; he must go into the shops and learn how these have to be modified in countless ways in order to ensure security and permanence of form and action under manufacturing and working conditions.

We must grasp these facts in order to understand the full significance of the terms *applied mechanics* or *practical mechanics*. The subject is co-extensive with the design and construction of all mechanisms, machines, and structures. It is the application of the principles of mechanical physics; and machine design is but one of its principal branches. It goes much farther than this, for it includes the stability of structures that are not machines, and it also embraces the problems dealing with the pressures and movements of liquids and fluids.

The Scope of this Series. Such being its comprehensiveness, our aim will be to deal in this series with matters that are not included in, or are touched on but lightly in, the courses devoted to PHYSICS and to MACHINE DESIGN. Even then the ground left to be covered is very extensive.

It is unnecessary to enter here into definitions of energy, force, mechanical units, mass, velocity, Newton's laws of motion, friction, conservation of energy, and so on. These are explained in a lucid manner in the course on PHYSICS, to which frequent reference should be made. The attempt will be made rather to approach this subject from a standpoint slightly different from that usually taken in text books. We think that the really valuable working applications of the principles laid down and illustrated by the bare diagrams common in text books are not made sufficiently apparent. The result is that the student, who cannot be expected to possess any familiarity with actual mechanisms and machines, is thus compelled to travel over a barren field devoid of real interest. But if now we endeavour to show as far as space will permit some of the actual mechanisms in which the principles sketched in the diagrams are embodied, the study will assume a greater interest.

Statics and Dynamics. Writers on these branches have treated them as though they were two distinct subjects, but the modern way is to regard matter, whether at rest or in motion, as alike subject to the action of forces, only that in the first they are in equilibrium, producing a condition of rest, and in the second they are not so.

Disguised Mechanisms. We desire to approach this general or broad subject of applied mechanisms from the point of view of leading principles of the simplest possible character, because without such knowledge there are many mechanisms which offer very great difficulties alike to the student and to the man who works among them. The real character of many of

these is disguised by their close resemblance to others which belong to a different category. Toothed wheels, connecting rods, various constructions in which leverage is the principle without being very apparent, epic cl c trains, etc., will be instanced in due course as affording examples of this kind.

Fundamental Facts. We start with the four facts of matter, force, equilibrium, and motion. All matter is subject to the action of forces. When these are balanced we say the body is at rest, or in equilibrium, which is the same as saying that the forces to which it is subject are mutually self destructive, or balanced. Yet the stresses—the technical way of denoting the action of various forces—may be of a most intense character in a body at rest. A bridge is at rest or in stable equilibrium, yet every one of its members is subject to forces which pull, or thrust, or bend. If either member should yield to its stresses then equilibrium would be disturbed, and the static would be changed to a kinetic condition. So the stresses in a jib crane result in equilibrium, and as long as no portion yields the crane gives no sign of the forces which pull and thrust its members so severely.

The measure of a movement effected by a force is the equivalent of work done. This is represented by a definite area, enclosed either by a rectangle or by two sides of a rectangle and a third line, or curve, which varies in form with the variations in the character of the force. This is the principle not only of the indicator diagram, but of all diagrams in which work is represented graphically, or by plotted lines as distinguished from mathematical methods. Here the great value of squared paper is apparent, on which lines can be plotted in equal divisions. Vertical lines (or ordinates) generally represent forces or pressures; and horizontal ones (or abscissae) movements or displacements. Uniformly operating forces produce diagonal lines; varying and increasing forces, curved lines gradually rising from the horizontal towards the vertical.

Materials. Again, the student of applied mechanics may not, like the pure physicist and the mathematician, sublimely ignore the working aspects of things. He can only deal with line diagrams in bare calculations. But in the embodiment of such things in practice he has to handle real materials, with all the uncertainties that are inseparable from their behaviour, and this again involves questions of different kinds of stress, and their effects in strain. The strength of materials becomes of high importance, because the forces acting upon a mechanism would destroy it, either by distortion or fracture, if the strength were not carefully made to correspond with the particular stress imposed. It is therefore necessary to know first the nature, direction, and the intensity of the forces acting upon every element in a mechanism; and then the capability of a given material has to be determined to resist those forces, without distortion, fracture, or even fatigue.

Factor of Safety. Out of this arises the determination of a suitable factor of safety, which is an empirical factor deduced from diverse practice, or experiment. This looms large in design, for without it a slight extra duty imposed on a machine, or some incalculable stress, would result in fracture. It explains why a thickness is generally increased by from three to ten times that which the mathematical calculations alone would have determined; or put in another way, why a given material is only subjected, say, to one half, one fourth, or one tenth the stress obtained for it by test and calculation. This is one of the everyday differences between the deductions of pure mechanics and their application.

Rigidity. Though we speak of materials in mechanisms as rigid, the student must learn to modify that idea, since no material possesses absolute rigidity. All have the property of elasticity in greater or less degree, and this has a very important bearing on the problems of permanence of form, and alterations in strength under repeated applications of stress. Under some conditions of loading, a structure suffers more than under others. What is termed *fatigue* is a diminution of strength due to repeated applications of loads—live loads and alternating stresses chiefly. Disaster would inevitably result if a mechanism designed to carry dead loads only were subjected systematically to the imposition of live and alternating loads. The elasticity of bodies is turned to practical account in springs. These are an obvious exception to the general rule that rigidity is essential to the operation of mechanisms. Many owe their essential action to the interposition of springs, either to effect certain movements, or to check and deaden the effects of impact.

The plasticity of materials has to be taken account of also. Under sufficient pressure all metals flow like viscous liquids. This explains stretch and strain, deformation of mechanisms, and the behaviour of extruded metals and alloys, the manufacture of tubes and wires, etc.

Friction. The pranks which friction plays in mechanisms can only be studied properly in the workshops. It is often an evil, but it is also as often a most valuable aid, which is pressed into service in the numerous friction clutches, in some kinds of joints, in belt driving, and much beside. Allied to this is lubrication, by which the effects of friction are greatly diminished. Further, there is another aspect of the highest practical importance, that of extent of surfaces in contact, by increasing which the effects of friction are diminished until they become almost *nil* over a given unit of area, and the working life of surfaces in contact is prolonged for indefinite periods.

Again, friction vastly modifies the duty which a mathematical calculation would credit to a piece of mechanism. The work done is not that which is put into the mechanism, but something less, often very much less, and the ratio between the two is the "modulus" of the

mechanism. There is, further, the great fundamental distinction between the sliding and the rolling kind of friction, the latter being practically a frictionless device. Friction is a powerful modifying influence in the mechanics of water in motion, and account has to be taken of it in determining the diameters and the lengths of pipes, and the radii of bends, and the character of interior surfaces. It occurs also in the passage of air through pipes.

Kinematics. An important point to note now is that the study of applied mechanics has assumed a new interest and a different aspect in consequence of the work of Professor Reuleaux, who approached the subject from the point of view of the kinematics of machinery, or the relative motions of different parts. The old sharp divisions between the "mechanical powers" or the "simple machines" are no longer held to be sufficiently precise and accurate, since they are simplified by the newer and more rational treatment. In pursuance of this method, we will now consider what is involved in an elementary mechanism.

The Basic Conception of a Mechanism. The one essential feature in a machine, whether very simple or extremely complicated, is the mutual constraint of all its members, so that no single piece can receive or impart any movement without affecting the movements of all those to which it is connected. This definition obviously excludes a single element. It must contain two, or more, and here we must make a necessary distinction between a machine and a rigid framework or structure. A machine must possess capacity for movement in itself, even though that movement is constrained. Hence the fixed bed or base of a machine tool or an engine is not in itself a machine, but simply a support for the latter. A wheel or pulley rigidly forming part of its axle mounted on bearings is a machine, for though it is really one piece only, it comprises the lever, the fulcrum of which is in its bearings, and the length of arm is its radius. The bar termed a pinch bar is one piece, and not a mechanism, but lay a stone under it near one end for a fulcrum, and the two comprise a machine, or a lever of what is termed the "turning pair" type, the simplest elemental form possible. A screw is not a machine, but it is rendered so directly it is encircled by a nut.

Constrained Movements. Another essential feature is that the movements of a mechanism differ from those of a single piece. A bar must move in the direction in which force is applied to it. But connect it with one or more bars, and the movements of the entire system are controlled by their relationships. And so it is possible, knowing or arranging for the application of given forces on one portion of a system, to predicate the movements of the other portions, since they depend on the way in which the parts are mutually connected.

Yet again, in order that such constrained movements shall take place it is necessary to construct machines of rigid materials, as iron, steel, brass, etc. It is essential in order to preserve the forms unimpaired, for if these could become changed the mutual movements would be impaired. Out of this grows the necessity of proportioning strength to stress, in other words, of imparting such dimensions that the stresses and strains shall not exceed the pressures or tensions imposed by the externally acting forces.

It is, of course, always understood that when a machine is spoken of, it is something by which force or energy is transmitted into useful work, involving movement. But in the more comprehensive problems of applied mechanics work involving motion need not be assumed. A roof truss, or an arch, or a dam has no motion, yet each does work by virtue of its stability, due to the constrained relations of its various elements, and therefore the same principles are found present in each. The dynamic forces acting upon mechanisms produce motions of rotation (angular velocity) or of translation (linear velocity), and each may be uniform, accelerated, or retarded. These forces may be external, that is, imposed from without (external forces). These give rise to pressures, producing stresses. Stresses are defined, therefore, as resistances to alterations of form. If deformation occurs the body is strained. Stresses and strains occur both in static and dynamic problems. The idea of equilibrium must not be simply confined to the stable, unstable, and indifferent state of a body in balance. It must be extended to include the static condition of the body in itself, a term which denotes either that the body is stationary or moving with uniform velocity. Kinetic equilibrium signifies that a body is undergoing acceleration.

Centres. Coming now to the simple movements of bodies, we have the fact that these are referable to a centre, or point, or axis. This is obvious enough in the case of a rotating wheel. But it is convenient to assume the same thing in all motions — those of translation, as of rotation — only in the first named the centre is movable in space, and is often imagined to be situated at an infinite distance away. This is in harmony with the assumption of the mathematician that a straight line is an arc with a centre at infinite distance. It simplifies calculations and leads to no error. When a body has a movement of translation its supposed centre is then denoted an *instantaneous centre*, since its position changes instantly, a term, however, which has a wider application, to be seen presently. This assumption then covers all cases that can arise, including those in which a circle arc exists of immense radius, since the flattest arc must have a centre somewhere at a finite distance. These two movements, therefore, that of rotation and that of translation, include all movements that can exist. But these movements around a centre or axis may be complicated. Fortunately, nearly all those with which the mechanician has to deal occur in one plane, for which calculations are much simplified. When motions perpendicular

or in oblique relation to a plane surface occur, they introduce other problems. Few examples of these, however, will occur.

Instantaneous Centre. We may now explain more fully the value of the instantaneous or virtual centre mentioned just now. The difference between this and a fixed centre is that the first named changes its position constantly, while the latter is fixed. The virtual centre is explained by the relative motion of two rigidly constrained elements in a mechanism, the relative motion of which is unalterable, just as is that of the rim of a wheel moving round its axle, or a ball twirled at the end of a string held in the fingers. The relative positions of the body and its centre do not change with the rotation of the wheel or the ball in space. So, too, though the instantaneous centre of a moving body moves, it occupies a fixed relative position towards the *point path* of the moving body, or the essential points in that path, and the relative positions of the moving point and the virtual centre are determined by the distance between them, fixed rigidly by the connecting link of metal, or other material of the mechanism.

The instantaneous centre has no necessary relation to the *shape* of the point path, or path traced by the moving body. That may be straight, or a circle arc, or be of irregular shape. The essential fact is that any body moving in any path is at every successive instant moving tangentially to a line that connects its movement, rotational for an instant, with a centre of motion for that instant. And this movement, whatever the ultimate form of the point path delineated, coincides for each successive instant with that of a figure rotating round a centre.

Several results of a practical character follow. Since the point path lies at any instant tangentially to the virtual radius, all virtual radii for successive positions must pass through the virtual centre. The only case in which the virtual centre is at an infinite distance is that of two point paths moving in parallel lines.

An advantage of approaching the study of mechanics in this way is that principles are simplified. The fixed or permanent centre of a rotating wheel or axle becomes practically identical in its study with the instantaneous centre; often of course the two coincide absolutely.

Centrode. As the virtual centres change instantly in the general case of non-rotating bodies, they trace a path in their successive positions. This is termed the centrode, and the surface or locus of the virtual axis is termed the axode.

Elements. We next consider the meaning of what are termed *elements*, the name given to two pieces by which motion is so constrained as to render all other motions impossible, an absolute essential in machine design. This is done in numerous ways, but it is usual to classify all such devices under either one of two heads. First, they form either *turning*, or *sliding pairs*, the first being represented by the rotation of a shaft or pin in its journal or bearing, the second by the movement of an engine slipper-block between its guides, or of a die in a slot link; the first is a movement of revolution, the second one of translation. In both cases the movement is constrained to take place in directions only in one plane, and not at all in a direction perpendicular thereto.

A second classification is that into *lower* and *higher* pairs of elements, the first-named denoting a point contact only, the second a surface contact. The last-named is that which is almost universally employed in machinery, because of its greater durability. That of the higher pair, or surface contact, is only possible in plane motion, or movements of revolution, and of sliding.

Link-work. Mechanisms and machines are now regarded as being built up of link-work, comprising combinations of bodies and elements, termed kinematic links, and chains, and arranged as turning or sliding pairs. The distinction between a mechanism and a machine is, then, that between the elementary combinations, and the complete embodiment of these in a fixed base or standard which is a static body only, and a convenient means of support and attachment to the kinematic links and chains. Both statical and dynamical problems therefore are involved in the construction of machines and prime movers, and in this comprehensive manner we propose to regard our subject. If we pursue the subject of kinematic pairs one stage farther, we see that each element of such a pair may be combined rigidly with an element of another pair without interfering with the relative movement of either. Evidently, too, we are not limited to two such combinations, but there may be several such, and to such combinations the term *chain* is given. Out of this a large number of special cases arise, to which Reuleaux (just deceased, as these sheets are going to press) has given specific names, and a special notation, which are being crystallized in technical literature all the world over. The subject is rather too involved for treatment in a short series like the present, which must be comprised mainly of illustrations of practical mechanics simply explained, but the subject cannot be passed over without observation.

Unless we approach the study of applied mechanics on the lines indicated in the foregoing paragraphs, it is not possible to grasp the similar fundamental principles which underlie many mechanisms that have not even a superficial resemblance to each other; nor, on the other hand, is it easy to distinguish others which appear superficially to belong to the same group. The theoretical and the practical are thus found constantly overlapping, and in the practical is always included the question of cost, both of material and labour, a factor which may be neglected by the mathematician, but not by the designer of machinery, and this is often why one device is adopted in preference to another.

WITH

A FULL AND SIMPLE TREATMENT OF THE PRINCIPLES OF THE METRIC SYSTEM

TAUGHT BY

HERBERT J. ALLPORT, M.A. of Cambridge, Past Mathematical Master at Dunstable

A FIRST COURSE IN SIMPLE ARITHMETIC

By H. J. Allport

1. In any system of reckoning we must have a *unit quantity*—i.e. a quantity with which we compare the magnitudes of other quantities of the same kind. With this unit quantity or, more shortly, this *unit*—we use certain *numbers* to indicate how great any quantity is, when compared with the unit. By the number *one*, or 1, we mean a quantity which consists of a single unit. If we then place another quantity of the same sort by the side of this unit, we get a quantity which consists of *two*, or 2, units. By placing another unit quantity with these two, we get a quantity consisting of *three*, or 3 units, and so on. The next numbers are called *four, five, six, seven, eight, nine*; they are represented by the *symbols* or *figures* 4, 5, 6, 7, 8, 9.

NUMERATION

2. It is clear that we might go on in this way, letting each successive number have its own particular symbol. This, however, would be an impracticable arrangement, since we should have to remember the meanings of so many symbols. The following method is used instead:

Suppose we wish to count a given number of pebbles. We count out 9 pebbles, and 1 more. This gives us a quantity which we call *ten*.

We next count another ten, and continue until the pebbles are all arranged in groups of ten, and we have less than ten pebbles left.

Next, count out ten of these groups of ten, and put them together into one group. This group contains a quantity which we call a *hundred*. Go on forming these hundreds until the number remaining of the little groups is less than ten.

Next arrange the hundreds in groups of ten (each of the new groups will contain a quantity which we call a *thousand*) until there are less than ten of the "hundred-groups" remaining.

Proceeding in this way, we must evidently arrive at a point where the pebbles are arranged in heaps, of which there are less than ten.

The following names are given to the successive groups, after a thousand: *ten-thousand, hundred-thousand, million, ten-million, hundred-million, thousand-million, ten-thousand-million, hundred-thousand-million, billion*. A *million-billion* is called a *trillion*, and so on. We have thus arranged the number of pebbles in groups of ten, hundred, thousand, etc., by using no more than the 1, 2, 3, 4, 5, 6, 7, 8, 9. Such a system, of expressing numbers in words, is called *Numeration*. Since it is based on the figures *ten*, it is called the *Decimal System*.

3. *Ten* is called the *first power* of ten; a *hundred* the *second power* of ten, a *thousand* the *third power*, and so on.

NOTATION

4. We have seen how any number may be expressed in powers of ten, with the help of the figures 1, 2, 3, etc. We must now find some convenient way of representing this result by symbols.

Suppose our number is 4 ten thousands, 3 thousands, 5 hundreds, 8 tens, 9 units. Evidently, if we agree that the *position* of a figure shall show to which power of ten it refers, we need not write down the words "ten thousands," etc., and the above number would be written 43589. That is, we agree that the figure on the right hand shall represent units, the one to the left of it shall represent tens, the figure in the next place to the left shall represent hundreds, and so on. This is what is meant by the *local* value of a figure.

5. It frequently happens that some power of ten is missing from a number. We use the figure 0, called *nought* or *cypher*, to indicate this. For instance, in the number 5 thousands 2 hundreds, there are no tens and no units, so the number is written thus, 5200.

6. Names of the numbers between 10 and 100. The number 11 is called *eleven*, 12 is *twelve*, 13, 14, 15, are abbreviated from three-ten, etc., to thirteen, fourteen, etc.

20, or two-tens, is called *twenty*.

30, 40, 50, etc., are called *thirty, forty, fifty*, and so on.

7. In reading any number, such as 143589, we abbreviate "one hundred-thousand, four ten-thousands, three thousands, five hundreds, eighty, nine" into "one hundred and forty-three thousand, five hundred and eighty-nine."

8. The *figures* used in representing a number are called its *digits*.

ADDITION

9. Addition is the method for finding a number equal to two or more numbers taken together. The result of adding two or more numbers is called their *sum*.

The sign +, called *plus*, written between two numbers, denotes that they are to be added together.

The sign = is an abbreviation for "is equal to" or "equals."

10. The student must make himself perfectly familiar with the Addition Table, consisting of the sums of every pair of numbers less than 10. He must know, without mental effort, that $4 + 9 = 13$, otherwise he can never expect to become a rapid worker.

11. Example. Add together 1097; 48214; 34; 7916. We first add the units, $7 + 4 + 4 + 6 = 21$, *i.e.* 2 tens + 1. We *carry*—*i.e.* include—those 2 tens with the tens in the given numbers; thus $2 + 9 + 1 + 3 + 1 = 16$ tens, = 1 hundred + 6 tens. Carry this 1 hundred, and add it with hundreds, and so on. It is convenient to write down the given numbers under one another so that units come under units, tens under tens, and so on, drawing a line under the last number.

Thus:

	Say, mentally,
1097	6, 10, 14, 21; carry 2.
48214	3, 6, 7, 16, carry 1.
34	10, 12; carry 1.
7916	8, 16, 17, carry 1.
57261 *Ans.*	5

SUBTRACTION

12. Subtraction is the method for finding what number is left when a given number is taken away from a larger given number.

The result of subtracting one number from another is called their *difference*.

Plainly, the difference between two numbers is the number which must be *added* to the smaller to make it equal the greater.

The sign −, called *minus*, written between two numbers, denotes that the second is to be subtracted from the first.

13. Example. Subtract 1287 from 40529.

We have to find the number which, when added to 1287, will make 40529.

Write the smaller number under the larger, with the unit's figure under the unit's figure, etc., as in addition. Then, 2 added to 7, make 9. Put down 2. Next, 4 tens added to 8 tens make 12 tens. Put down 4, and carry 1 (*i.e.* 1 hundred). In this step we have made the eighty in the smaller number up to one *hundred* and twenty, and this one *hundred* is added to the 2 hundred in the smaller number. Hence, in the next step, we say 3 hundreds added to 2 hundreds make 5 hundreds. Put down 2. Next, 9 thousands added to 1 thousand make 10 thousands. Put down 9 and carry 1. Finally, 3 ten-thousands added to 1 ten-thousand, make 4 ten-thousands. Put down 3.

Thus:	Say, mentally,
40529	7 and 2 make 9,
1287	8 and 4 make 12, carry 1,
	3 and 2 make 5,
39242 *Ans.*	1 and 9 make 10, carry 1,
	1 and 3 make 4.

14. By using the above method for subtraction it becomes a very simple matter to subtract the sum of several given numbers from another given number (greater, of course, than that sum). The student will see the importance of making himself thoroughly familiar with this method when he gets to "long division."

Example. Subtract the sum of 1092, 20875, and 435, from 50171.

Put the figures down exactly as in addition, putting the 50171 first, and separating it by a line from the numbers below. Add the three lowest digits in each column, and make the sum up to the top line, as in Art. 13.

50171	Say, mentally,
1092	5, 10, 12, and 9 make 21, carry 2,
20875	5, 12, 21, and 6 make 27, carry 2,
435	6, 14, and 7 make 21, carry 2,
	3 and 7 make 10, carry 1,
27769 *Ans.*	3 and 2 make 5.

MULTIPLICATION

15. Multiplication is the method for finding the *sum* of a given number of repetitions of a number. Thus 12 multiplied by 5 means $12 + 12 + 12 + 12 + 12$, *i.e.* 60.

The number which is multiplied is called the *multiplicand*, and the other number is called the *multiplier*. The result is called the *product*. The *multiplier* and *multiplicand* are called *factors* of the product, and the product is called a *multiple* of either of these factors.

The sign of multiplication is ×. Thus, 12 multiplied by 5 is written 12×5, and is read "12 times 5."

16. In forming the product of two numbers, it is immaterial which number is taken for the multiplier. For instance, in the product 4×5, if we make 4 the multiplier, the result is $5 + 5 + 5 + 5$, *i.e.* 20; while, if we make 5 the multiplier, the result is $4 + 4 + 4 + 4 + 4$, *i.e.* 20, as before.

17. It is now necessary to make a *Multiplication Table*, *i.e.* a list of the results of multiplying all the numbers from 1 to 12 by every number from 1 to 12.

MULTIPLICATION TABLE.

1	2	3	4	5	6	7	8	9	10	11	12
2	4	6	8	10	12	14	16	18	20	22	24
3	6	9	12	15	18	21	24	27	30	33	36
4	8	12	16	20	24	28	32	36	40	44	48
5	10	15	20	25	30	35	40	45	50	55	60
6	12	18	24	30	36	42	48	54	60	66	72
7	14	21	28	35	42	49	56	63	70	77	84
8	16	24	32	40	48	56	64	72	80	88	96
9	18	27	36	45	54	63	72	81	90	99	108
10	20	30	40	50	60	70	80	90	100	110	120
11	22	33	44	55	66	77	88	99	110	121	132
12	24	36	48	60	72	84	96	108	120	132	144

The first column consists of the numbers 1 to 12. The second column is obtained by adding

each number to itself, and therefore represents the result of multiplying the first column by 2. The third column is obtained by adding the second to the first, and therefore gives the result of multiplying the first column by 3. The fourth column is obtained by adding the third to the first, and so on.

18. Example 1. Multiply 4507 by 6.

Here we have to find the result of repeating the number 4507 six times and adding. We first take six times the units' figure, then six times the tens' figure, then six times the hundreds, then six times the thousands, and add the results together. The process is abbreviated thus:

4507	Say, mentally,
6	six 7's, 42, carry 4,
	six 0's, 0, and 4,
27042 *Ans.*	six 5's, 30, carry 3,
	six 4's, 24, and 3, 27.

Example 2. Multiply 5287 by 578.

Here we find 500 times 5287, 70 times 5287, and 8 times 5287, and add the results.

Thus:

5287
578
*26435
*37009
42296
3055886 *Ans.*

Explanation. Place the multiplier so that its unit's figure comes under the unit's figure of the multiplicand. By exactly the same process as in Example 1, we find that 5 times 5287 = 26435. Therefore 500 times 5287 = 2643500 (since each digit now has 100 times its former value. Art. 4). Next we find 7 times 5287 = 37009, and therefore 70 times 5287 = 370090. Finally, 8 times 5287 = 42296.

* Note that it is unnecessary to affix the ciphers in the separate products, since the *position* of each digit indicates its value. Obviously we have only to *place the first figure of each product immediately under the multiplying digit.*

19. Multiplication by Factors. If the multiplier has factors, we may, instead of using the above process, multiply by one factor, then multiply this product by another factor, and so on, till we have used all the factors.

Example. Multiply 72486 by 147.

$147 = 3 \times 7 \times 7.$

Then,

72486
3
217458
7
1522206
7
10655442 *Ans.*

20. Suppose, in Art. 14, the several numbers to be subtracted are equal to one another; suppose, for instance, we have to take away 3 times 10875 from 50171.

The work is written thus:

	Say, mentally,
50171	three 5's, 15, and 6 = 21, carry 2,
10875	three 7's, 21, 23, and 4 = 27, carry 2,
3	three 8's, 24, 26, and 5 = 31, carry 3,
	three 0's, 0, 3, and 7 = 10, carry 1,
17546 *Ans.*	three 1's, 3, 4, and 1 = 5.

DIVISION

21. Division is the method for finding how many times one given number can be subtracted from another given number.

The first number is called the *divisor*, the second number is called the *dividend*, and the number of times the subtraction is done is called the *quotient*. The number which remains after the last subtraction (if any does remain) is called the *remainder*.

The sign ÷ written between two numbers denotes that the first is to be divided by the second.

Division is also denoted by writing the dividend above the divisor with a line between them.

Thus 28 ÷ 7 and $\frac{28}{7}$ each mean that 28 is to be divided by 7.

22. Division may be looked upon in two ways. Suppose we have to divide 28 marbles amongst a certain number of boys. Then (1) if we are told the number of boys we can find how many marbles each will get. (2) If we are told how many marbles each boy is to have, we can find how many boys will get a share.

23. It is plain from the definition of division that

divisor × quotient + remainder = dividend.

24. The multiplication table enables us to divide any given number by a number less than 13.

Example 1. Divide 3729 by 7.

We have to divide 3 thousands 7 hundreds 2 tens 9 units by 7. We cannot divide the 3 by 7, since 3 is less than 7. But these 3 thousands are equal to 30 hundreds, which, with the 7, make 37 hundreds; 37 hundreds ÷ 7 gives 5 hundreds for quotient, and 2 hundreds remainder. Calling these 2 hundreds 20 tens, and adding the 2 tens of the given number, we get 22 tens to divide by 7. This gives 3 tens for quotient and 1 ten remainder. The 1 ten is 10 units, which, with the 9 units of the given number, make 19 units. 19 units ÷ 7 gives 2 units quotient, and 5 units remainder.

Thus the whole quotient consists of 5 hundreds 3 tens 2 units, *i.e.* 532, and the remainder is 5.

The work is written thus:

	Say, mentally,
7)3729	seven 5's, 35, and 2, 37, carry 2,
532 quotient	seven 3's, 21, and 1, 22, carry 1,
+ 5 rem. *Ans.*	seven 2's, 14, and 5, 19.

Example 2. Divide 13,188 by 12.

Thus :

```
12 ) 13188          twelve 1's, 12, and 1, 13,
                      carry 1.
     1099 quotient  twelve 0's, 0, and 11,
     -------------    carry 11.
                    twelve 9's, 108, and 10, 118,
                      carry 10,
                    twelve 9's, 108.
```

The above process is called *Short Division*.

25. Division by 10, 100, *etc.*

Suppose we have to divide 1297 by 10. Now, 1297 = 129 tens + 7. $\therefore$ 1297 ÷ 10 = 129 quotient + 7 rem. Therefore, to divide a number by 10, we have only to cut off the unit's figure, this unit's figure becoming the remainder.

Similarly, to divide by 100, we must cut off *two* figures. Thus, 1297 ÷ 100 = 12 quotient + 97 remainder.

26. Long Division. If the divisor is greater than 12, the quotient is usually found by the process known as long division.

Example 1. Divide 39576 by 31.

It is usual to put the dividend between brackets, turned outwards, and to write the divisor in front of it.

```
31 ) 39576 ( 1276 quotient
             -------------
      85
      237
       206
        20 rem
```

Now, 31 cannot be divided into 3 ten-thousands, so there will be no ten thousands in the quotient. But 3 ten-thousands = 30 thousands, which, with the 9 thousands of the dividend, make 39 thousands. 31, divided into this, gives 1 thousand quotient. We write 1 (thousand) in the quotient, multiply the divisor by 1,000, *i.e.* multiply by 1, but begin writing under the *thousands* place of the dividend, and subtract the result from the dividend. *These two operations can be done in one process, as in Art. 20.*

The remainder is 8 (thousands). Writing the 5 (hundreds) of the dividend with the 8 (thousands) we get 85 (hundreds). 85 divided by 31 gives 2 (hundreds) for quotient. Write 2 (hundreds) in the quotient, multiply the divisor by 2, and subtract the product from 85. (Art. 20.)

The remainder is 23 (hundreds). Proceeding as before we see that 237 (tens) divided by 31 gives 7 (tens) quotient, and after multiplying the divisor by 7 and subtracting, we get 20 (tens) remainder. Bring down the 6 (units) from the dividend, making 206 (units) in all ; divide by 31, which gives 6 (units) quotient, and leaves remainder 20 (units).

The complete quotient is therefore 1276, and the remainder 20.

Note : (i.) that the remainder at any stage can never be as great a number as the divisor ;

(ii.) always, after "bringing down" a digit from the dividend, we must put a digit into the quotient. If, after bringing down a digit, we still have a number less than the divisor, we put a cipher, 0, in the quotient, and then bring down another digit from the dividend.

Example 2. Divide 67846250 by 843.

Here we do not get a number big enough to be divided by 843 until we use 4 figures of the dividend—*viz.* 6784 (ten-thousands). To help us to guess what figure is required in the quotient, consider only the 8 (hundreds) of the divisor and the 67 hundreds of the 6784 (ten-thousands). We know *eight* 8's = 64, so the figure in the quotient *may* be 8. If this gives too great a product to subtract from 6784, then we must try 7 in the quotient, and so on.

```
843 ) 67846250 ( 80481 quotient.
                 ---------------
       4062
        6905
         1610
          767 rem.
```

After getting our first remainder, 40 (ten-thousands), and bringing down the 6 from the dividend, we see that 406 (thousands) divided by 843 will give no thousands for quotient. Therefore, put 0 in the quotient, and bring down another digit from the dividend. (*See* Note ii. above.)

27. Division by Factors.—If the divisor has factors, none of them being greater than 12, we may get the required quotient by dividing first by one of the factors, then dividing this quotient by another factor, and so on, till we have used all the factors. The only difficulty of such a process not yet explained is the formation of the remainder after each division.

Example 1. Divide 12459 by 56.

Thus :

```
7 | 12459
8 |  1779 + 6 rem.                  } whole rem. =
       222 + 3 (seven's) rem.       } 3 × 7 + 6 = 27.
```

Since 56 = 7 × 8, we first divide 12459 by 7, which gives 1779 (sevens) and 6 rem. We next divide the 1779 sevens by 8. We thus form the 1779 sevens into 222 groups, which each contain 8 sevens, *i.e.* 56, and find we have 3 sevens left over. These 3 sevens and the 6 left after the first division make the total rem. 27.

Example 2. Divide 157651 by 20.

```
20 ) 15765|1
     7882 + 11 rem.
```

Use the factors 10 × 2. Divide by 10 as in Art. 25, giving 15765 and 1 rem. Divide this quotient by 2, giving 7882 and 1 rem. The total rem. is therefore 1 ten + 1, *i.e.* 11.

Example 3. Divide 82769 by 343.

$343 = 7 \times 7 \times 7.$

Hence:

$$\begin{array}{l|l} 7 & 82769 \\ 7 & \overline{11824} + 1 \\ 7 & \overline{1689} + 1 \\ & \underline{241} + 2 \end{array} \quad \left.\begin{array}{l} \\ \end{array}\right\} 1 \times 7 + 1 = 8 \left.\begin{array}{l} \\ \end{array}\right\} \begin{array}{l} 2 \times 49 + 8 \\ = 106 \text{ rem.} \end{array}$$

Form the rem. after the second division exactly as in Example 1. We now have 1689 groups of 49. Dividing these by 7 we get 241 quotient, and 2 groups of 49 rem. Therefore, we have altogether $2 \times 49 + 8 = 106$ rem.

EXAMPLES 1

1. Find the value of 27291 + 142386 + 22 + 907 + 600298, and write the answer in words.
2. The sum of two numbers is 1789402; the greater is 1002453. What is their difference?
3. What number must be added to the sum of 1234, 35926, 153, 2975, in order that the sum may be 50000?
4. In a train containing 389 passengers, 177 are first and second class, 262 are first and third. How many are there in each class?
5. Multiply (*a*) 14265 by 297; (*b*) 309804 by 8053.
6. A man bought 129 sheep at 35 shillings each, and 82 at 45 shillings each. If he sells the whole at 42 shillings each, how many shillings does he gain or lose?
7. Divide (*a*) 1512315 by 105; (*b*) 692853 by 528; (*c*) 316115141284 by 519602.
8. A man sold a number of cattle for £840 which cost him £720, thus gaining £2 on each animal. What did each animal cost him?
9. Divide 270 marbles amongst 3 boys, so that for every two the first boy gets, the second may get three, and the third may get four.
10. How many pounds of sugar at 3*d*. a pound must be given in exchange for 82 pounds of coffee at 18*d*. a pound?

DECIMALS

28. We may now extend the system of notation explained in Art. 4 so as to include quantities which are less than the unit.

If we have a quantity ten of which would make a unit, this quantity is called a *tenth*.

Similarly, a quantity ten of which make a tenth, is called a *hundredth*. Continuing in the same way, we have a *thousandth*, a *ten-thousandth*, etc.

29. Suppose we have to measure a given line. Having chosen our unit, we can find how many complete units the line contains. Let the number be 127, and suppose there is still some portion of a unit left.

We next find how many *tenths* there are in this portion. Say there are 6 tenths, and that some portion of a tenth remains. We now measure how many *hundredths* this portion of a tenth contains, say 4 hundredths.

And so on, until either there is no remainder, or we have measured the line to as great a degree of accuracy as we require.

The length of the line has now been found to be 127 units 6 tenths 4 hundredths, and, making the same convention as in Art. 4, viz. that the *position of a digit shall indicate to which power of ten it belongs*, we may omit the words "units," "tenths," etc., *provided we make it clear which is the unit's digit*. This is done by placing a point (called the *decimal point*) between the unit's digit and the tenth's digit. Thus the above number is written 127·64, and is read "one hundred and twenty-seven point six four."

The rules given for addition, subtraction, etc., also apply to decimals.

Addition in Decimals.

30. Example. 27·295 + ·0287 + 591·68 + 9·1846.

Write the numbers so that the same powers of 10 come under one another, as in Art. 11, or, what is the same thing, write the numbers so that the decimal points come under one another. Then proceed exactly as in Art. 11, adding the ten thousandths first, 6, 13, carry 1, etc.

$$\begin{array}{r} 27{\cdot}295 \\ {\cdot}0287 \\ 591{\cdot}68 \\ 9{\cdot}1846 \\ \hline 628{\cdot}1883 \end{array} \text{ Ans.}$$

Subtraction in Decimals.

31. Example. Subtract ·07205 from 21·651.

Write the first number under the second, so that the point comes under the point. Proceed as in Art. 13, remembering that we may consider there are 0's above the 0 and 5, since in 21·651 there are no ten thousandths and no hundred thousandths.

$$\begin{array}{r} 21{\cdot}651 \\ {\cdot}07205 \\ \hline 21{\cdot}57895 \end{array} \text{ Ans.}$$

Say, mentally, 5 and **5** make 10, carry 1.
10 and **0** make 10, carry 1.
3 and **8** make 11, carry 1, etc.

Multiplication in Decimals.

32. Example 1. Multiply 87·432 by 564.

Place the multiplier so that *its unit's digit comes under the right-hand digit of the multiplicand*. Then proceed as in Art. 18, Example 2, *i.e.* place the first figure of each product underneath the multiplying digit. The decimal point of the answer will then be directly under the decimal point of the multiplicand.

$$\begin{array}{r} 87{\cdot}432 \\ 564 \\ \hline 43716{\cdot}0 \\ 5245{\cdot}92 \\ 349{\cdot}728 \\ \hline 49311{\cdot}648 \end{array} \text{ Ans.}$$

Example 2. Multiply 31·56 by 5·49.

As before, place the unit's figure of the multiplier, *i.e.* the 5, under the right-hand digit of 31·56, and proceed as above.

$$\begin{array}{r} 31{\cdot}56 \\ 5{\cdot}49 \\ \hline 157{\cdot}80 \\ 12{\cdot}624 \\ 2{\cdot}8404 \\ \hline 173{\cdot}2644 \end{array} \text{ Ans.}$$

of life we call *animal* It would be well to consider both for a moment

The *difference* between the two is, perhaps, most apparent in their *food*. Vegetables can live on inorganic food and animals cannot. The vegetable can live on carbon, oxygen, hydrogen, or nitrogen, and build them up into organic compounds The animal, on the contrary, can only live on such organic compounds, and can therefore only exist on a vegetable world. The vegetable *stores* the force which the animal *spends*. A vegetable may be aptly compared to a hard working father accumulating large stores of wealth, while the animal rather resembles the spendthrift son who dissipates it Of course, vegetables do spend some of their force, and animals, on the other hand, store some of theirs

Large parts of vegetables (the layers of bark, etc) are lifeless and are subject to such slow changes as to resemble minerals; so within animal bodies many processes are performed by which force is stored and not expended, and such parts resemble vegetables in their action, so that no actual hard and fast line can be drawn

Five phenomena of life here claim attention BIRTH, GROWTH, DEVELOPMENT, DECAY, and DEATH

Birth marks the definite beginning of separate existence, and is an essential of every living thing, in that it implies that all life, without exception, is obtained by inheritance; and never since it first originated, as far as we know, has begun *de novo* Before the days of exact research, the contrary was believed to be true, and the presence of life in decaying animal and vegetable matter was supposed to prove that life could exist without previous life It is needless now to show how the progress of science proved this to be a fallacy, demonstrating that every form of lowest life did and could only spring from a parent of the same species Every effort to prove the theory of spontaneous generation has so far failed, and where adequate care is taken to exclude life from animal matter, no putrefaction takes place, and no living forms are found.

Growth is not confined to living beings, but in them it takes place in a totally different way from that in the inanimate world In a crystal, for instance, or in rock formation, growth takes place by the mechanical addition of layer after layer, the mass itself taking no part in the process; and growth continues, moreover, indefinitely In a living organism growth is the result of change and increase in every part throughout the being, and this growth, so long as it is healthy, has strict limits beyond which it cannot continue.

Development is a phenomenon which has no parallel in the inanimate world As growth is an increase in quantity, so development is an increase in quality, being the perfect adapting of means to ends, of machinery to work through continual use. Every organ of the body, including the brain, is thus developed by use, and becomes not only larger but more vigorous, and better adapted for its work.

Decay is now understood to be a constant manifestation of life. It used to be thought that life consisted in a power to resist decay, and it was only when life ceased that decay began. It is now found, not only that decay is an incessant accompaniment of life from birth, but that perhaps it is positively more active during life than afterwards. It is true that the effects of decay are not obvious during life, as, on the other side of the balance, the opposite force of repair or growth serves as a counterpoise to keep the body in "dynamic equilibrium"; but when the summit of life is passed, repair gets more and more feeble, and at last, ceasing in death, leaves the field free for the ravages of decay. Life is not, then, a power that resists decay, but, on the contrary, a force that cannot be manifested without it; every movement, every look, every thought, involving the decay and destruction of a certain amount of body tissue.

Death is a phenomenon quite peculiar, and necessarily so, to life; for it is obvious that nothing can cease to live save what has lived. But it is not so much an interruption of life as the final attainment of an end which was a necessity from the beginning, and towards which every act of life tended Exactly as every beat of an eight day clock is a step towards the final stopping of the mechanism, which is definitely arranged to take place at the end of eight days, so every movement of the body, and every day that it exists, is a step towards that end for which it was constructed, every body being made exactly like a clock, to run a definite time, although, of course, it may be stopped before—as a clock with the finger—by disease or accident No cause, however, is known why, in a body, when the machinery has become perfectly well balanced, and decay and repair are equal, it should not continue so indefinitely, seeing that it is self-repairing, instead of wasting away after a certain number of years.

The Three Signs of Human Life. The signs of life that are essential to life may be said to be three in number *breathing*, *the beating of the heart*, and *warmth* *Breathing* is an essential sign of life, and generally there is respiration *seventeen times a minute* The air food, unlike the solid and liquid food, must be incessantly taken, and there can therefore be no life without breathing.

The *beating of the heart*, again, is essential to life, generally about *seventy times a minute*. The supply of fresh food to the body cells by means of the circulation of the blood is a necessity of life. When the circulation ceases life must cease.

These two signs are concerned with the maintenance, or the vegetative side, of animal life The third is more connected with the purely animal side, or the spending of force, and is *heat*. The living body is always warm in some parts, its general average heat being that of hot water about 98½ degrees Fahrenheit. To maintain this requires considerable force, but it is essential to life. A body that is cold everywhere is dead.

These, then, are the three essential signs of life. It may be thought strange that no mention has been made of *movement* as an inherent quality of life, and particularly and obviously of animal life. The truth is that the mere fact of an animal being able to move is not more wonderful than that a steam engine can do the same, and movement is therefore not a special sign of life. Moreover, active life can exist without any movement at all, save the two which have been indicated—breathing and the beating of the heart.

Life as a Journey. Let us now look on life in another aspect—as a journey. The journey may be roughly divided into three stages, each lasting about twenty-five years.

The first stage, which is all uphill, consists of growth from one to twenty-five years of age. During this time is being built the house which has to be lived in for seventy-five or eighty years, but unlike other houses, it is occupied while being constructed.

During this time force is being stored up faster than it is being spent, despite the fact that the expenditure now is so heavy. Not only are all movements active at this time, but the size of the body is continually increased. Still, it is mainly now that those reserves of force on which the maintenance of health so largely depend are accumulated.

The great essential during this time is an abundance of suitable food. Roughly speaking, the body at birth is a quarter of its full height; at two and a half years it is one half; at ten, three quarters; while the full height is reached about twenty. This shows the necessity for an abundance of the best building materials to construct it.

The second stage in the journey lasts twenty-five to thirty years—or from twenty-five to fifty or fifty five—and should be a period of steady good health, when the condition of dynamic equilibrium or the balance of life is preserved, as is not the case in the other two stages. In the first stage repair exceeds destruction; in the last, destruction exceeds repair. In this third stage, however, the two should be balanced. So much food in proportion to the size of the body is not required now, as it no longer grows. Moderation in all things is perhaps the best motto.

The Decline of Life. The third stage is that of decline, and extends from fifty or fifty-five to seventy-five or upwards. The change from perfect health is at first most gradual, and in some may not really begin till nearly sixty years are reached. The manner of life may, of course, accelerate or retard the change, which soon becomes more marked. It may generally be described, where healthy, as a shrinking, drying, and stiffening of the tissues. Less food is required as the lamp of life burns more dimly; and to those who die what may be called natural deaths, the last change comes very gradually and gently. When we speak of "natural deaths" we mean such as are the result of the running down of the clock of life, rather than those due to the premature stopping of the works through accident or disease, so largely the offspring of carelessness or ignorance.

It is quite a part of physiology to understand that the life force in each man is a definite quantity exactly parallel to that stored in a watch spring; and each human being is constructed to "go," or to live, a certain definite time. Those who thus die from the expiration of their life force can alone be truly said to die natural deaths. Only about one in every nine so die in this country, the other eight do not live out their days.

Length of life necessarily is not, however, always an unmixed good, and should not in itself be an aim. It is well and wise, of course, to guard against what may be termed suicides of carelessness and ignorance, and it is partly for this purpose that these pages are written. But it is of infinitely greater importance that the life so guarded should be spent wisely and well, for the good of others and the glory of our Creator.

Whole Life. This brief survey of Life would be quite incomplete were it entirely confined to a description and definition of that part of it alone which is concerned with physical existence.

The old division of man's life into three parts—body, soul, and spirit—is now largely justified by physiological psychology. The mere body life consists in *existing*, the soul or animal life in *moving* and spending the life force; and the highest, or spirit—intelligent, moral, and intellectual life—is what really constitutes *living* to a man.

Let us repeat,

Body and Body Life Existing;
Soul and Animal Life Moving;
Spirit and Spirit Life Living

It is not a little startling to note in this connection the extreme accuracy of St. Paul's three-fold description of life to the Athenians: "For in Him we live (spirit life) and move (soul or animal life) and have our being (bodily life.)"

The Psychic life is partly conscious and partly unconscious. Broadly it may be said that about half the spirit and animal life is conducted within the range of consciousness and about half without, wholly or in part, while all the life connected with existence merely is regulated entirely unconsciously. The government of the body is thus conducted quite unconsciously; while that of the spirit is partly the unconscious outcome of character, instinct, and perhaps higher influences, and partly that of conscious will and purpose.

We cannot pursue this part of life further as the subject properly belongs to PSYCHOLOGY. It is mentioned here, because Life, after all, is one, and it is well to recognise its higher as well as its lower side. We can now turn definitely to study PHYSIOLOGY.

THE PLAN OF THE BODY

The individual man, as a whole, is increasingly forgotten both in physiology and in medicine, owing to the extraordinary minuteness and exactness with which each part and organ is examined and described. Specialism is rampant,

A little consideration will show the truth of the statement that the decimal point of the answer will be directly under the decimal point of the multiplicand. In Example 2, when we multiply by 5 (*i.e.* 5 units) it is clear that 5 times 6 hundredths = 30 hundredths, and therefore we put the 0 in the *hundredths* place of the multiplicand. Similarly, in the second line we are multiplying by 4 *tenths* and therefore the product is written one place further to the right than if we were multiplying by 4 *units*; *i.e.* we again put down our first figure under the multiplying digit and the decimal point of the product will again be under the point of the multiplicand.

NOTE. It is evident, from the way the product is formed, that the number of decimal places in the product will always be equal to the sum of the number of decimal places in the multiplier and the multiplicand. Thus, in Example 2, there are two places of decimals (*i.e.* two figures to the right of the point) in 31·56, and two places of decimals in 5·49, and we found 2 + 2 = 4 places in the product 173·2644.

DIVISION IN DECIMALS

33 (*a*) Division of a decimal by a whole number.

Example 1. Divide 18·2754 by 4.

4)18·2754
4·56885

As in Art. 24, we divide 4 into 18 (units) and have 4 (units) quotient and 2 units remainder. Since the 4 is the unit's figure of the quotient, we write the decimal point immediately after it. Then, the 2 units remainder and the 2 tenths of the dividend make 22 tenths to be divided by 4, and so on. Having reached the 4 (ten thousandths) of the dividend, we find 8 (ten-thousandths) quotient and 2 remainder. This remainder is 20 hundred-thousandths, which when divided by 4 gives 5 (hundred-thousandths) and no further remainder.

Example 2. Divide 18·2758 by 11.

11)18·2758
1·66143636...

Here we find the digits 3, 6 repeated indefinitely in the quotient. Decimals of this sort will be fully considered later.

Example 3. Divide 354·43 by 184.

184)354·43(1·92625 *Ans.*
1704
483
1150*
460
920
. . .

Proceeding as in Art. 26, we find the first figure of the quotient is obtained by dividing 184 into 354 units. Having now reached the decimal point in the dividend, we also put the decimal point in the answer, and go on as before.

* At this stage there is a remainder 115 hundredths. We bring down 0 from the dividend, and obtain 1150 thousandths, etc.

(*b*) Division by a decimal.

Example 4. Divide 10·6603 by 7·85.

Here 7·85 is 785 hundredths, and 10·6603 is 1066·03 hundredths; so that the required quotient is obtained by dividing 1066·03 by 785.

Therefore, to divide by a decimal, move the point as many places to the right as will make the divisor a whole number: move the point in the dividend the same number of places to the right. Then proceed as in Example 3.

Thus: 785)1066·03(1·358 *Ans.*
2810
4553
6280
. . . .

Example 5. Divide 176·4 by ·00012.

12)17640000
1470000 *Ans.*

Here, to make the divisor a whole number, we have to move the point 5 places. Therefore we also move the point 5 places to the right in the dividend, first writing enough 0's after the 176·4 to enable us to do so.

EXAMPLES 2

1. Find the value of 48·207 + 3·04862 + 1·0095 + 504·8 + 101·63 + ·925.
2. Add together 59·6425, ·018, 77, 2·475, 2·1, ·00021.
3. Subtract (*a*) 7·98624 from 14·571; (*b*) 52·005 from 729·08147.
4. Find the difference between (*a*) 11·435 and 7·2183; (*b*) 589 and ·589.
5. Multiply (*a*) 72·94 by 325; (*b*) 1·096 by 5·076; (*c*) ·2815 by ·5128.
6. Multiply (*a*) 53·8624 by 9·625; (*b*) ·8775 by 1·476.
7. Divide (*a*) 2·5463 by 125; (*b*) 381·116 by 11; (*c*) 1516·8 by 4800.
8. Divide (*a*) ·43843 by 17; (*b*) 71380·6 by 124.
9. Divide (*a*) ·43 by ·0025; (*b*) ·1864302 by 3·102; (*c*) ·01077687 by 5·49; (*d*) 50·1 by ·00835.
10. Divide (*a*) 300 by ·0025; (*b*) 95·0985875 by 34·75; (*c*) 40·7295 by ·00862.
11. How many times can 4·63 be subtracted from 364·1985, and what will be the remainder?
12. Find the dividend if the divisor, quotient and remainder be respectively 725·625, 81·2, ·34175.
13. Simplify $\frac{\cdot057}{22\cdot8} + \frac{3\cdot9}{\cdot104}$.
14. Simplify $\frac{6\cdot44}{\cdot023} + \frac{1\cdot02}{\cdot34}$.
15. Simplify $\frac{\cdot6 \times 1\cdot8 \div \cdot0012}{5\cdot7 \div \cdot019}$.
16. Simplify $\frac{4\cdot35 \times 60 \div \cdot29}{\cdot015}$.

LIFE, A CONDITION OF INCESSANT CHANGE

By Dr. Schofield

PHYSIOLOGY is the science of the functions, or the process of life. It is one of four divisions of Biology; the other two being Morphology or the forms of life, and Embryology or the development of life. Our special subject is Human Physiology, as distinguished from general animal physiology on the one hand, and vegetable physiology on the other.

The interest of the study is intense and may be compared to a visit to some great industrial centre, and the examination of all the wonderful processes by which some exquisite fabric is produced. We will take a journey together through the wonderful workshops of life and seek thoroughly to understand not only the exquisite details, but the governing forces, and, it may be, at times to discern the hidden Power that is the ultimate source of all Energy.

What is Life? What, then, is life? To this there are many answers. Let us take some of practical value. *Life is a condition of incessant change, dependent on the ceaseless operation of destruction and repair.* It is really a state of balance or dynamic equilibrium; that is, a balance dependent on the equality of the weight in each scale, the loss on one side being counterbalanced by the gain in the other.

Life, again, is a force of a special character, or rather a power which uses the common forces of Nature for a unique purpose. Consider for a moment the difference between an egg that is fertile and can produce a chicken—and thus contains vital power—and one that cannot. Both are organic compounds of a similar nature and chemically the same; both are the products of living beings. But the difference between them is immense.

For a time both eggs appear alike, and apart from the use of external force no difference can be seen. Both will go bad and decompose into inorganic solids and gases, and the living egg will have no advantage over the dead one. But let one of the common forces of nature—heat—be applied to both, and the difference between the two will be at once apparent. It will be seen in a few days that the life in the one egg is a capacity to appropriate and use this force progressively and eventually to produce a chicken; while the other has no such power. This chicken, in common with all other living beings, must continue to appropriate force in the shape of heat, light, and food, or the life ceases. When life does not exist, these forces cannot be used, and only hasten the process of decay.

A Directing Agency. Life, then, is a special purposive power—inherent in the living cell or organism—to use external force and manifest it in special phenomena; but it is not an independent physical force or energy, being, on the contrary, a directing agency, wholly dependent for its manifestations on the common forces of nature.

But the word Life, again, has two meanings. It may refer to the process of life in its maintenance, or it may refer to its manifestation in action. That part which refers more especially to the building up of force or the maintenance of life, we call *vegetable*, and that which is most concerned with the spending of it in the action

of life we call *animal*. It would be well to consider both for a moment.

The difference between the two is, perhaps, most apparent in their food. Vegetables can live on inorganic food and animals cannot. The vegetable can live on carbon, oxygen, hydrogen, or nitrogen, and build them up into organic compounds. The animal, on the contrary, can only live on such organic compounds, and can therefore only exist on a vegetable world. The vegetable *stores* the force which the animal *spends*. A vegetable may be aptly compared to a hard working father accumulating large stores of wealth, while the animal rather resembles the spendthrift son who dissipates it. Of course, vegetables do spend some of their force, and animals, on the other hand, store some of theirs.

Large parts of vegetables (the layers of bark, etc.) are lifeless and are subject to such slow changes as to resemble minerals; so within animal bodies many processes are performed by which force is stored and not expended, and such parts resemble vegetables in their action, so that no actual hard and fast line can be drawn.

Five phenomena of life here claim attention: Birth, Growth, Development, Decay, and Death.

Birth marks the definite beginning of separate existence, and is an essential of every living thing, in that it implies that all life, without exception, is obtained by inheritance; and never since it first originated, as far as we know, has begun *de novo*. Before the days of exact research, the contrary was believed to be true, and the presence of life in decaying animal and vegetable matter was supposed to prove that life could exist without previous life. It is needless now to show how the progress of science proved this to be a fallacy, demonstrating that every form of lowest life did and could only spring from a parent of the same species. Every effort to prove the theory of spontaneous generation has so far failed; and where adequate care is taken to exclude life from animal matter, no putrefaction takes place, and no living forms are found.

Growth is not confined to living beings, but in them it takes place in a totally different way from that in the inanimate world. In a crystal, for instance, or in rock formation, growth takes place by the mechanical addition of layer after layer, the mass itself taking no part in the process; and growth continues, moreover, indefinitely. In a living organism growth is the result of change and increase in every part throughout the being, and this growth, so long as it is healthy, has strict limits beyond which it cannot continue.

Development is a phenomenon which has no parallel in the inanimate world. As growth is an increase in quantity, so development is an increase in quality, being the perfect adapting of means to ends, of machinery to work through continual use. Every organ of the body, including the brain, is thus developed by use, and becomes not only larger but more vigorous, and better adapted for its work.

Decay is now understood to be a constant manifestation of life. It used to be thought that life consisted in a power to resist decay, and it was only when life ceased that decay began. It is now found, not only that decay is an incessant accompaniment of life from birth, but that perhaps it is positively more active during life than afterwards. It is true that the effects of decay are not obvious during life, as, on the other side of the balance, the opposite force of repair or growth serves as a counterpoise to keep the body in "dynamic equilibrium"; but when the summit of life is passed, repair gets more and more feeble, and at last, ceasing in death, leaves the field free for the ravages of decay. Life is not, then, a power that resists decay, but, on the contrary, a force that cannot be manifested without it; every movement, every look, every thought, involving the decay and destruction of a certain amount of body tissue.

Death is a phenomenon quite peculiar, and necessarily so, to life; for it is obvious that nothing can cease to live save what has lived. But it is not so much an interruption of life as the final attainment of an end which was a necessity from the beginning, and towards which every act of life tended. Exactly as every beat of an eight day clock is a step towards the final stopping of the mechanism, which is definitely arranged to take place at the end of eight days, so every movement of the body, and every day that it exists, is a step towards that end for which it was constructed, every body being made exactly like a clock, to run a definite time, although, of course, it may be stopped before—as a clock with the finger—by disease or accident. No cause, however, is known why, in a body, when the machinery has become perfectly well balanced, and decay and repair are equal, it should not continue so indefinitely, seeing that it is self repairing, instead of wasting away after a certain number of years.

The Three Signs of Human Life. The signs of life that are essential to life may be said to be three in number: *breathing*, *the beating of the heart*, and *warmth*. *Breathing* is an essential sign of life, and generally there is respiration *seventeen times a minute*. The air food, unlike the solid and liquid food, must be incessantly taken, and there can therefore be no life without breathing.

The *beating of the heart*, again, is essential to life, generally about *seventy times a minute*. The supply of fresh food to the body cells by means of the circulation of the blood is a necessity of life. When the circulation ceases life must cease.

These two signs are concerned with the maintenance, or the vegetative side, of animal life. The third is more connected with the purely animal side, or the spending of force, and is *heat*. The living body is always warm in some parts, its general average heat being that of hot water about 96½ degrees Fahrenheit. To maintain this requires considerable force, but it is essential to life. A body that is cold everywhere is dead.

These, then, are the three essential signs of life. It may be thought strange that no mention has been made of *movement* as an inherent quality of life, and particularly and obviously of animal life. The truth is that the mere fact of an animal being able to move is not more wonderful than that a steam engine can do the same, and movement is therefore not a special sign of life. Moreover, active life can exist without any movement at all, save the two which have been indicated—breathing and the beating of the heart.

Life as a Journey. Let us now look on life in another aspect—as a journey. The journey may be roughly divided into three stages, each lasting about twenty-five years.

The first stage, which is all uphill, consists of growth from one to twenty-five years of age. During this time is being built the house which has to be lived in for seventy-five or eighty years, but unlike other houses, it is occupied while being constructed.

During this time force is being stored up faster than it is being spent, despite the fact that the expenditure now is so heavy. Not only are all movements active at this time, but the size of the body is continually increased. Still, it is mainly now that those reserves of force on which the maintenance of health so largely depend are accumulated.

The great essential during this time is an abundance of suitable food. Roughly speaking, the body at birth is a quarter of its full height; at two and a half years it is one half; at ten, three-quarters; while the full height is reached about twenty. This shows the necessity for an abundance of the best building materials to construct it.

The second stage in the journey lasts twenty-five to thirty years—or from twenty-five to fifty or fifty-five—and should be a period of steady good health, when the condition of dynamic equilibrium or the balance of life is preserved, as is not the case in the other two stages. In the first stage repair exceeds destruction; in the last, destruction exceeds repair. In this third stage, however, the two should be balanced. So much food in proportion to the size of the body is not required now, as it no longer grows. Moderation in all things is perhaps the best motto.

The Decline of Life. The third stage is that of decline, and extends from fifty or fifty-five to seventy-five or upwards. The change from perfect health is at first most gradual, and in some may not really begin till nearly sixty years are reached. The manner of life may, of course, accelerate or retard the change, which soon becomes more marked. It may generally be described, where healthy, as a shrinking, drying, and stiffening of the tissues. Less food is required as the lamp of life burns more dimly; and to those who die what may be called natural deaths, the last change comes very gradually and gently. When we speak of "natural deaths" we mean such as are the result of the running down of the clock of life, rather than those due to the premature stopping of the works through accident or disease, so largely the offspring of carelessness or ignorance.

It is quite a part of physiology to understand that the life force in each man is a definite quantity exactly parallel to that stored in a watch spring; and each human being is constructed to "go," or to live, a certain definite time. Those who thus die from the expiration of their life force can alone be truly said to die natural deaths. Only about one in every nine so die in this country, the other eight do not live out their days.

Length of life necessarily is not, however, always an unmixed good, and should not in itself be an aim. It is well and wise, of course, to guard against what may be termed suicides of carelessness and ignorance, and it is partly for this purpose that these pages are written. But it is of infinitely greater importance that the life so guarded should be spent wisely and well, for the good of others and the glory of our Creator.

Whole Life. This brief survey of Life would be quite incomplete were it entirely confined to a description and definition of that part of it alone which is concerned with physical existence.

The old division of man's life into three parts—body, soul, and spirit—is now largely justified by physiological psychology. The mere body life consists in *existing*; the soul or animal life in *moving* and spending the life force; and the highest, or spirit—intelligent, moral, and intellectual life—is what really constitutes *living* to a man.

Let us repeat,

Body and Body Life Existing;
Soul and Animal Life Moving;
Spirit and Spirit Life Living.

It is not a little startling to note in this connection the extreme accuracy of St. Paul's three-fold description of life to the Athenians: "For in Him we live (spirit life) and move (soul or animal life) and have our being (bodily life)."

The Psychic life is partly conscious and partly unconscious. Broadly it may be said that about half the spirit and animal life is conducted within the range of consciousness and about half without, wholly or in part, while all the life connected with existence merely is regulated entirely unconsciously. The government of the body is thus conducted quite unconsciously; while that of the spirit is partly the unconscious outcome of character, instinct, and perhaps higher influences, and partly that of conscious will and purpose.

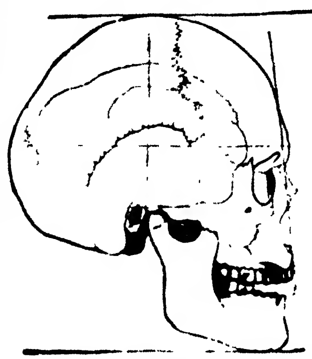
We cannot pursue this part of life further as the subject properly belongs to PSYCHOLOGY. It is mentioned here, because Life, after all, is one, and it is well to recognise its higher as well as its lower side. We can now turn definitely to study PHYSIOLOGY.

THE PLAN OF THE BODY

The individual man, as a whole, is increasingly forgotten both in physiology and in medicine, owing to the extraordinary minuteness and exactness with which each part and organ is examined and described. Specialism is rampant,

not only in medicine but in physiology; and we will therefore take particular pains, both here and in the sections of health and ill health, to keep the man as a living personality, an essential unity, always before the mind.

Remember that the body is not a mere town, full of different factories, carrying on various trades. It is an organic whole, and what makes it one is not the similarity or unity of the machines and processes, for they are unlike and many; but it is the unity of the one governing force, the mind, and especially the unconscious mind, which presides over the body. Nothing in the body is *merely* mechanical, although there is much mechanism; all is vital, all is united in one great aim—the health and well-being of the individual.



1. EUROPEAN SKULL, SHOWING FACIAL ANGLE OF 75°.

Having briefly discussed the question of what life really is, and of what its principal features consist, and having taken a survey of its various stages, let us now examine an individual man as he stands erect before us, and see what we can learn of the human body from an external view.

The Exterior. Notice, first of all, the shape of the *head*, the large proportion the brain bears to the face, greater than in any animal. Remember that the *brain* occupies the whole of the head [1] behind and above a line drawn across the eyebrows and continued to the lobes of the ears. Observe that the forehead and the face and eyes lie as nearly as possible in the same plane, and that the line from the forehead, with that from the ear to the lower edge of upper teeth, forms almost a right angle; an arrangement only suited for the erect attitude, and obviously most inconvenient if man went on all fours, when "he could see and smell nothing but the ground" (Holden). As it is, his *eyes* can command the greatest possible range of vision, their scope being only limited on the inner side by the bridge of the nose, when vision is taken up by the fellow eye. Observe the eyebrows above, keeping the "sweat of the brow" from deluging the eyes. The eyes should, for beauty, be rather deeply set, prominent eyes being never seen in ancient art. The nose, too, is not placed, as in animals, so as to scent prey in advance, which to them is of the greatest use, but so as to receive odours from below, and especially of all food going into the mouth. The *mouth*, again, to man, is of as much value for articulation in speaking as for eating, and hence the jaws are not prominent, and the cavities within are specially arranged for the reception and conduction of sound.

Now study, finally, the unique form of expression that lies in the muscles of the face. The science of physiognomy is most valuable and interesting, for undoubtedly these facile muscles get insensibly moulded by the passions and habits of the man, whose character can be far better read by the lines round his mouth than by the so-called "expression" of the eye, which really depends on the facial muscles, or the bumps on his head, often caused by thickening of the bone.

The *ear*, the great beauty of which is its small size and perfect lobe, is not able, as in animals, to turn forward or backward to catch distant sounds, man having other means of protection from his enemies and of providing his food than the faculties of scent and hearing.

Now look at the *neck*. Note the strong, bony column surrounded by muscles everywhere but in front, where you see the prominent "Adam's Apple," the front of the larynx, or voice-box.

2. THE SKELETON.

Framework of the Body. Look now at the *body* [2], and notice generally how all its complicated framework in the living man is hidden and blended so as to present but one harmonious whole. Observe that the *chest* is much broader than it is thick; an arrangement only found, among mammals, in man, and in some of the highest apes. This arrangement throws the arms much more apart than the legs, giving them a much wider range for grasping, but making them weak and useless for walking. In other animals, on the contrary, the upper part of the chest is narrow, to allow the forelegs to come close together, and stand directly under the trunk they support. Notice the bony framework of the chest, which is formed by the ribs and breastbone.

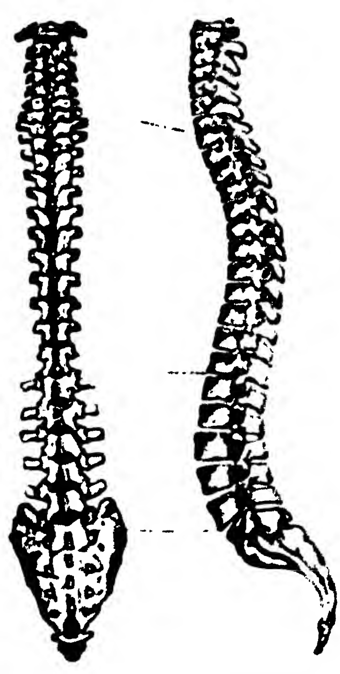
It will interest you to observe that if these were continued all the way down we could not stoop, and could hardly move. These special points just enumerated, and others, show that man is not a quadruped that has learned to stand erect. His arms are not in any sense

forelegs, for his whole body and every limb is designed for the *erect attitude* and for that alone. The lower half of the body, *the abdomen*, therefore, is protected instead by a firm but yielding wall of strong muscles, added to which are elastic fibres. In animals who walk on all-fours these fibres form a complete elastic belt to support the body. Note, moreover, that the heaving of the chest and beating of the heart are all conducted within the thorax, or chest; so that the three great organs necessary to existence—the brain inside the skull, the lungs and the heart beneath the ribs—are thus entirely protected from all ordinary injury.

3. BONES OF HAND.

Divisions of the Body. We have alluded to the bony framework, and we may note one or two facts about it now. If we divide the body into six parts—four limbs, trunk, and head and neck—we find each part contains about thirty bones (counting the ribs in pairs), there being about *two hundred* in all the body. The height of the body depends mainly on the length of the bones of the lower limbs.

Observe, now, the *arms* generally, and their position: the looseness of the shoulder joints, adapted for universal movement, but not to sustain the weight of the body. Note that the forearm does not fold on the upper arm, but to its inner side towards the mouth, a more useful position. Look at the *hand* and wrist [3], which alone contain some twenty-seven bones. The supple strength of the wrist; the value of the thumb; not placed in a line with the other fingers, but in advance of them, and so as to touch them all; the nails, arranged to support the finger-tips, and yet not to interfere with their touch, are worthy of note. The hands are marvels of precise and adapted mechanism, capable, not only of executing every variety of work, of expressing many emotions of the mind, but of executing its orders with inconceivable rapidity.



Back View. Left Side View

4. THE SPINE.

Beautiful Proportions. Take, now, a wider view of the *beauty* of the human figure. Let the person stand with feet together and outstretched arms. His breadth should now be equal to his height; and the four sides of a perfect square will in a perfect figure touch the soles of the feet, the crown of the head, and the tips of the fingers. Of the height, the hand should measure one-tenth part, the forearm one-quarter, the head one-eighth, the face one-tenth, the leg (from knee-cap to foot) one-quarter; while the greatest width of the chest should measure one-fifth, the least one sixth; the breadth of the nostrils should equal the length of the eye; the mouth should be half as long again; the forehead should be the same breadth as the nose is long. Such a figure is a perfect human structure.

Coming down the *trunk*, observe that the rugged outlines in statuary in the male figures are all due to muscular development, indicating strength; while the smoother curves of the female figures are due to the preponderance of fat. Observe, by the way, how every part is so moulded that those forms, the commonest in human designs and machines, straight lines and angles, hardly exist in the body at all. In the erect position one of the beauties of the body is its perfect balance, and the way it conforms to the laws of gravitation.

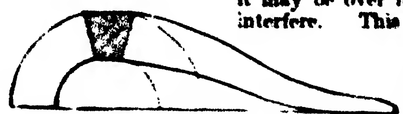
Notice, now, that the *waist* is a natural and not an artificial product, but that it forms, as we have said, not an abrupt angle, but a hollow curve from above downwards, and an *ellipse*, and not a circle, horizontally. Observe that in the male figure the shoulders are rather broader, and in the female slightly narrower than the hips, so that the male form somewhat resembles a single inverted cone, the female a double one.

Notice how broad and strong the *haunch bones* are as compared with those of animals, since the erect position requires large bony attachment for muscles to maintain it; part of the weight of the internal organs also is directly supported by the pelvis in the erect position.

Now before looking at the legs turn to the *back*, and observe the spring given to the figure by the beautiful double curve of the backbone, so admirably adapted, as we shall see in another chapter, to break shocks going to the brain. In the infant the spine is quite straight, and no animals possess the spinal curves we do, which are only required in the erect position.

The head and spine contain the centres of the nervous system; the upper part of the body or chest is the seat of the respiratory and circulatory systems; the lower part, or stomach, is the seat of the digestive and excretory systems; and the limits of the locomotor system.

Another mode of looking at the structure of the body is more anatomical. Man is a member of the vertebrata. His body has an internal skeleton, of which the chief feature is the central axis or backbone. Considering the skull and backbone as one, the body may be said to be built up of two tubes [7]. The smaller posterior or neural tube includes the cavity of the skull and the vertebral canal. Within this tube is lodged the nervous centre, or engine, of the body. The anterior, or body, tube is much larger, consisting of the face above, and the neck and trunk below, and it contains the four nutritive systems of life, so that the whole body in section is like an 8 with the lower circle immensely exaggerated [8]. The limbs, of course, are not tubular, and merely form part of the machinery. If we look again at 7, we shall see that in the first tube there is a curved division. Recalling our first simile of the human engine and boiler and machinery, we see that the limbs, etc., are the machinery, the posterior tube the engines and force that move them, and the anterior (darkly shaded) tube the human boiler that generates the force; this boiler, like one in a steam engine, has an upper and lower part. The upper part, above the curved line, is where the steam is generated (in lungs) and sent to the engine (the brain) by the heart. The lower part, below the curved line, is where the fuel is burnt (the stomach) and the ashes and refuse drop through (the intestines). So that the analogy between the two is close and striking.



6. DIAGRAM OF ARCH OF FOOT.

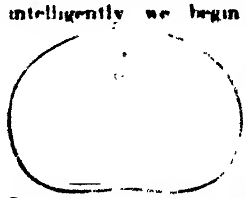
Centres of Control. Let us now consider how the various parts of the body are worked and controlled. There are two distinct seats of government in the human body: the one in the upper brain, or cortex, the other principally in the very centre of the human body. That in the upper brain, or cortex, is the human will and the conscious mind. It is absolutely autocratic, supreme, godlike, in its qualities, and responsible only to the Creator. This imperious and imperial human will has absolute control given to it over the animal part of the human life—that is, over the part that consists in the using of force, which includes the nervous and locomotor systems, and the special senses. The other government, situated in the lower part of the brain and spinal cord and in the centre of the body—in front of the spine and behind the stomach—is of an entirely different order. It is, indeed, a most complete and absolute system of "home rule." The imperial government of the brain proper has no power over any of its actions; absolute though it may be over its own domain, here it cannot interfere. This home-rule government, or "the unconscious mind," has full and undisputed sway over life itself, particularly over vegetable, as distinguished from animal, form—that is, over the generating and storing of vital force, rather than over its usage. Over the latter, indeed, it has some slight control, but only so far as to enable it to assist the former. To put this more plainly: The four systems that lie in the body—*digestive, circulatory, respiratory,* and *excretory*—may be termed the nutritive systems, being designed for the maintenance and storage of life forces. They are almost entirely under the control of the involuntary nerve centres.

7. THE TWO TUBES IN THE BODY.

Voluntary and Involuntary Acts. In physiological language, that part of the nervous system which we have referred to as the imperial government is termed *voluntary*, because it is under the control of the will. Thus, when we wish to exert force by lifting the forearm, a message is sent from the central part of the nervous system to the muscles, which contract in obedience to our desire. But such acts as breathing and the beating of the heart, over which we have very little control at all, which are controlled by what we have termed the home rule government, are, because of this lack of conscious control, termed *involuntary* acts.

From this division of government, we see that we have no power over the processes or functions of life, our sole concern being rightly to use the forces continually placed at our disposal. We do not digest our food, move the heart, or even the lungs, by any constant and direct effort of will. If, indeed, it were so, and the whole of our bodies were under our own control, the management of our bodies would so absorb the mind as to leave it no leisure to attend to external affairs at all. As we study Physiology intelligently we begin dimly to discern the Wisdom that alone has made possible human and intellectual life.

To be continued



8. SECTION OF THE TWO TUBES.

[A short glossary of terms used in Physiology is given on the following page.]

A SHORT DICTIONARY OF PHYSIOLOGY

ACETABULUM The socket in hip joint into which thigh bone head fits.
Afferent nerve A nerve which carries an impulse to the brain.
Afferent vessel Carries blood to lungs or other purifying organ.
Alimentary Pertaining to food.
Ampulla Part of the internal ear in vertebrates.
Aorta The main artery of the body.
Appendix A blind tube extending from the caecum.
Arterial Pertaining to an artery. Pure blood.
Artery A vessel carrying blood from the heart.
Articulation A joint.
Assimilation The process of converting digested food into body tissue.
Auricle A cavity in the heart.

BICEPS The muscle which bends the fore arm.
Bicusp'd The first two grinding teeth in each jaw.
Bile The secretion of the liver.
Bile-duct Tube leading from liver to intestine which carries the bile.

CAECUM A blind tube in intestines.
Calcaneum The heel bone.
Canine The eye teeth outside the incisors.
Capillaries Microscopic blood vessels having very thin walls.
Cardiac Pertaining to heart.
Carotid The main artery carrying blood to the head.
Carpal Pertaining to the wrist.
Carpus The bones of the wrist.
Cartilage Gristle, the covering of the ends of many bones.
Caval veins The large veins which carry impure blood to the heart.
Centrum The body of a vertebra.
Cephalic Pertaining to the head.
Circulatory organs The structures which convey blood and lymph.
Coagulation The process of clotting in blood.
Cochlea A bony part of internal ear.
Columnar epithelium Epithelium made of elongated cells placed at right angles to the surface.
Condyle A bony projection which helps to form a joint.
Connective tissue That which binds or connects tissues together.
Contractile — Having contracting power.
Cornea - The membrane in fore part of eye through which light passes.
Corpuscles - Microscopic cells in blood or lymph.
Cortex The outer layer of brain.
Costal Pertaining to the ribs.
Cranial nerves Nerves which arise from the brain.
Cranium - The brain case or skull.

DENTINE - The hard part of teeth.
Dermis The inner layer of skin.
Diaphragm The muscle separating the chest from the body.
Dorsal - Pertaining to the back.
Duct - A tube, generally carrying the secretion of a gland.

EFFERENT nerves - Nerves transmitting impulses from the brain.
Efferent vessels—Vessels which carry pure blood from the lungs.
Embryology - Science of development.
Epidermis - The outer protective layer of skin.
Epiglottis— An elastic structure which prevents food entering air-passages.
Epithelium—Cells which cover surfaces on or in the body.
Excretion The processes by which waste matters are expelled.
Extensor A muscle which straightens or extends a limb.

FEMORAL Pertaining to thigh.
Femur The thigh bone.
Fibula The smaller bone on the inner side of the lower leg.
Flexor A limb-bending muscle.
Foramen A hole in a bone through which a vessel or nerve passes.

GALL - Bile.
Gall-bladder The bag in which the bile is stored.
Ganglion Collection of nerve-cells.
Gastric Relating to the stomach.
Gastric juice The digestive fluid of the stomach.
Glenoid cavity Socket into which head of upper arm bone fits.
Glottis The opening into windpipe.
Grey matter The cellular part of the nervous system.

HÆMOGLOBIN The colouring matter of blood which carries oxygen.
Hepatic Pertaining to the liver.
Humerus The upper arm bone.

INSERTION The end of a muscle attached to a movable part.
Intercostal Between the ribs.
Iris The coloured part of eye.

LACTEALS Lymphatic vessels of the intestine.
Larynx The voice box.
Ligament A strong fibrous band connecting two bones.
Lymph A clear colourless fluid containing corpuscles.
Lymphatic gland A swelling on a lymphatic vessel.

MAXILLA A bone of the jaw.
Membranous labyrinth Part of internal ear.
Mesentery A membrane which holds the intestines in position.
Metabolism The chemical changes which take place in the body.
Metacarpus The bones of the palm.
Metatarsus The bones of the instep.
Mitral Valves on the left side of the heart, between auricle and ventricle.
Molar A permanent check tooth.
Mucous membrane A soft membrane lining a tube.

NERVE-CELL The essential part of a nerve unit.
Nerve-fibre The thread extending from a nerve cell.
Neural Pertaining to the nerves.
Neuron A nerve cell and its prolongations.
Nuchal Pertaining to the neck.

ŒSOPHAGUS - The gullet.
Oral - Pertaining to the mouth.
Orbit Cavity containing eyeball.
Origin The end of a muscle attached to a fixed part.
Osmosis - The process by which fluids or substances pass through a membrane.
Ossicle —A little bone.
Ovary - The female sexual organ containing eggs.
Ovum—An egg cell.

PANCREAS—The sweet-bread, a gland in the abdomen.
Papilla —A little projection.
Parotid—A gland producing saliva.
Patella—The knee-cap.
Pelvis— The bones to which the hind or lower limbs are joined.
Pepsin—A digestive ferment in gastric juice.
Peptone—A soluble substance produced in digestion.
Pericardium—The membrane in which the heart lies.
Peristaltic—The movements of the intestine.
Phagocyte—A colourless corpuscle.
Phalanges - The finger and toe bones.
Pharynx —Cavity at back of mouth.
Physiology—Science of function.
Portal— Pertaining to the vessels which carry blood to the liver.
Pulmonary - Pertaining to lungs.
Pyloric - The end of the stomach nearest the intestine.

RADIUS - The bone of the forearm on the side of the thumb.
Retina - The internal coat of eye.
Rouleaux Little rolls or chains of blood corpuscles.

SALIVARY Glands producing saliva.
Scapula The shoulder-blade.
Sclerotic - The external hard coat of the eye.
Sebaceous gland—A gland producing an oily secretion.
Segmentation The early divisions of a germ cell.
Semilunar Valves on left side of the heart between ventricle and aorta.
Sensation A state of consciousness.
Serum The colourless fluid element of the blood.
Spinal cord—The mass of nerve tissue with the spinal column.
Spleen - A large gland in the abdomen.
Stationary air - Air which remains still in the lungs in breathing.
Sternum—The breast-bone.
Sympathetic nervous system - Part of the nervous system regulating blood supply and other functions.
Synovia The fluid which lubricates the joints.
Synovial—That which secretes synovia, e.g. the synovial membranes.

TARSUS - The bones of the ankle.
Tendon The strong fibrous band which attaches a muscle to a bone.
Thoracic duct - Tube which receives lymph and opens into the great neck veins.
Thorax —The chest.
Thymus - A ductless gland near heart.
Thyroid A ductless gland in neck.
Tibia - The shin-bone.
Tidal air Air taken in at an ordinary breath.
Trachea—The windpipe.
Tricuspid - Valves on right side of heart, between auricle and ventricle.
Tympanum The drum of the ear.

ULNA - The bone of the forearm on the little-finger side.
Ureter The tube which carries urine from the kidney.

VALVE— A flap in a vessel or tube preventing backward flow of fluid.
Vein - A vessel carrying blood towards the heart.
Venous - Pertaining to a vein. Impure blood.
Ventricle - The thick-walled chambers of the heart which by contracting force blood into the arteries.
Vertebra — A bone of the backbone.
Viscera - The internal organs.
Vocal chords - Two thin folds of elastic tissue in the larynx.

WHITE matter—The nerve fibres of the nervous system.

THE PLACE OF LITERATURE IN ONE'S LIFE

By J. A. HAMMERTON

EVERYONE is convinced that it is necessary to take food in order to live. The proposition is so obvious that it would be sheer foolishness to call it in question. It comes within the range of demonstrable facts, such as that fire burns, that rain makes us wet. But there are other varieties of facts, quite as important to know and understand, that cannot so readily be demonstrated. Of these is the fact that some knowledge of literature is essential to the living of a well-balanced life.

One can, no doubt, adduce many instances which seem to prove the opposite, so far as either side of the question is capable of proof. The Vanderbilts, the Rothschilds, came to great things as men of no literary attainments; the founder of the first family, it is said, could neither read nor write. Alas, with all his gains he remained poor; and poor, indeed, are all who, waxing rich in worldly gear, still lack that imperishable furnishing of the mind which can be acquired only in communion with the great intellects that have made the world's literature.

The Food of the Mind. Not poor merely, but intellectually dead. For as surely as the body dies for lack of food, or grows unhealthy by improper feeding, so does the mind of man languish if mental nourishment be withheld—languish and die. We have all met persons of gross bodies whose minds were vacant places where no beautiful things were, but where there might have been good store had the impulse come, the effort been made, at the proper time, toward literary culture.

After all, it is, perhaps, not so difficult to prove that the food of the mind is as essential as the food of the body; for he who has been well nourished in the physical sense and starved mentally has but to open his mouth to advertise his condition.

It is not to be inferred from this that we deem the reading of books the be-all and end-all of mental culture. Far otherwise. The simile of feeding may still be pursued. For just as there is over development of the physical man differently, but equally, by over eating or excessive athleticism, it is no uncommon thing for a man to become so attached to mere book learning that he errs at the other extreme from the physically gross person. It would, however, involve too much discussion, though entirely apposite to our argument, to enter into the numerous considerations suggested by those other classes of one-sided people who devote themselves with passionate energy to some one pursuit which, however worthy of itself and in relation to others—novel reading, for example; playgoing, book-collecting, philately—is, when allowed to occupy a man's whole thoughts, but little better than foolishness. All alike are one-sided people—those sunk in mere animal indulgence, those immersed in book learning, those who pursue with sad, superfluous devotion some one "hobby." Mental culture, of which literature is an essential part, but only a part, produces a well-balanced, four-square life.

The "Literary" Point of View. Our purpose, then, is not to praise book-learning with any indiscriminate rhetoric; nor to exalt it unduly. There are nobler things than to be rich in the lore of the world; but, let a man be never so well endowed in all the attributes of good character, he will still be the better man by some measure of acquaintance with the treasures of literature; in fact, it is hard to know how he may acquire the more worthy traits of character without the ministry of literature, direct or indirect. A man who confesses that he has no knowledge of books tells us that the blinds are close drawn on some of the windows of his soul.

Only within comparatively modern times has a class arisen which makes literature the sum of its life; the professional literary class. In ancient times the authors were men of action—travellers, architects, statesmen. They did not begin and end in a world of books; they fought battles, they adventured in strange lands, they

governed provinces, they made laws, they reared buildings; and what they wrote was in large part derived from their contact with the life of the world in which they participated, not as authors on the quest for "copy," but as men. The same is true, in a measure, of the monks, so long the conservators of letters; they were primarily concerned with the business of living and the contemplation of a future life. The literary man of our day is in constant danger of looking at life from the literary point of view as distinct from that of human experience, and his real success is to be measured mainly by his evidence of deliberate detachment from the conditions which have made it possible for so many members of the community to become professional critics of life rather than men waging the common battle of existence.

The Purpose of Reading. Clearly, for the literary class, as such, we can have nothing to offer in this treatise. Literature is not a part of their life: it is everything to them, after religion, and perhaps, in some cases, before religion. Our concern is with those in whose lives literature has an eminent part to play: ennobling—that is, with the vast majority of our countrymen.

Although the quotation is hackneyed, Bacon's dictum on reading remains unsurpassed:

"Read not to contradict or confute, nor to believe and take for granted, nor to find talk and discourse, but to weigh and consider."

Here in two dozen words is the best advice that can be given as to the purpose of reading and its place in life. One of the greatest errors of our national system of education has been the acceptance of the idea that our public schools educate the younger generation. We read of some man that he was "educated at Manchester Grammar School"; of another, that he "completed his education at Oxford." Not even our universities educate. At best, public schools and the universities prepare us for education; render us capable of being educated. No more do they achieve; cannot; for the wisest of men is learning still when he attains to the end of all things mortal.

"To weigh and consider"—that is the true purpose of all useful reading. We have not to read for the mere storing of our minds with multitudinous facts, nor yet with sensuous fancies, which seem to be the chief results of the tremendous consumption of modern printed matter. In truth, there is no reason to complain in these days that the British public reads too little; it reads quite enough, but without discrimination. In order to "weigh and consider," it is obvious that there must be discretion. And at what age comes discretion? If we knew that, we should know all. Which brings us to a point of great importance.

Reading that does not count. Biography teems with stories of prodigies who had "read everything" at fifteen. We have met in the flesh more than one of these wonders grown old, and have formed no exalted estimate of their literary judgment. We warn our readers still under twenty years of age to avoid at all costs the suspicion of being prodigies in reading. By grace of genius a boy or girl of nineteen may be a poet, but the average healthy youth unvexed by genius is not usually at that age, and rarely earlier, capable of really intelligent reading. He may, truly, have read much and derived genuine and rational pleasure from his reading, but it will be in later life that the critical faculty will assert itself and judicial appreciation of that early reading be disengaged from the vague sensations of remembered pleasure and repulsion left by the books read before the development of the faculty of criticism. We are making no dogmatic assertion as to the incidence of that faculty; but we submit that it is seldom present before the age of twenty; and for that reason we are not with those who contend that all the reading that matters in one's life has been done from sixteen to twenty-one or thereabouts.

The Beginning of Serious Reading. The young people of sixteen who are "for ever reading something or other" are more than likely, it may be roundly asserted, to become the least intelligent of readers, the least truly cultured. Not seldom do they in later life acquire a positive distaste for books; and in any case the greater part of their juvenile reading will count for little or nothing, since it was undertaken at a time when their understanding was unequal to the occasion. Children should be permitted at most to acquire the *habit* of reading, and to that end the commonest of common boys' or girls' papers serves its purpose. But by fifteen or sixteen years of age, when the greater number of British boys and girls are following some sort of employment, they are in train for guidance, and one may reasonably presume to direct their attention to such standard works as will at once give pleasure, while steadily fostering the taste for what is good and enduring in our literature—though it were worse than foolish to expect from readers so young any would-be judicial opinions as to the qualities of the books they read. We do not picture those of tender years "weighing and considering" what they read. They have read as they have played skipping-rope or blind man's buff—for pleasure; and rightly so. But, just as in our later 'teens we put these games behind us, so we should then begin to read for a different purpose—the true purpose—the culture of the mind. With crude results at first, inevitably, yet thrilling with the now awakening knowledge that books are not merely inventions for passing the time, but the most precious of all the agencies for carrying us into a full manhood.

Models to be Avoided. The purpose of art, we are told, is "to please." But all that pleases is not art. Professor Drummond, as a boy, was in love with the red-painted inside of a toy trumpet, and wondered why God had not made the whole world red. Many a child has had the same delight and wonder. "Deadwood Dick" and "Sweeny Todd" have pleased innumerable thousands of healthy boys, but

neither is a work of literary art. The true pleasure of art is that arising from the joy of consciously appreciating the work of the artist, and realising that it has wrought in our mind to its uplifting, to our better understanding of the world in which we live, and the people around us. That is the kind of pleasure which should come when the reader has begun to understand that he is reading seriously, and not until then has literature begun to take its place in his life.

Now, if this be true—and we apprehend no great opposition to our contention—it should be clear that youth is only a time for acquiring the habit of reading, not for forming judgment or presuming to pass criticism. So we contend that the voracious readers of young years are by no means models to be pointed out, except as worthy of avoiding. We have no admiration for them, and, as they are too often neurotic examples, we leave them callously out of our account. We write for ordinary healthy-minded young men and women, who are neither book-worms nor muscular numskulls.

Bring Something to Your Book. To them we say that they must bring something to the reading of books as well as take something away. They must bring some qualities of imagination, common-sense, sympathy, in addition to the elements of school-learning, in order that what they read they may "weigh and consider," and that when they have done this they may feel they have taken another step along the unending path of knowledge and self-culture. They will have their ordinary affairs to attend to: their daily tasks in office or workshop, their studies in commerce or applied science—language, engineering, whatever their taste or circumstances may dictate—their health exercises and recreations, their love-making; since reading for literary culture must not displace any of these essentials of manhood and womanhood.

We would have none become mere book-worms any more than we would have them become mere animals, examples of bone and brawn. Yet even the humblest fitter in an engineering shop is capable of enlarging and beautifying his life by a judicious knowledge of literature. We know an engineer's labourer whose taste in books is as cultured and accurate as that of many who live by criticism, whose knowledge of our standard authors is extensive and sound, who can write with great literary charm (he has contributed to the *Cornhill* and *Longman's Magazine*), and remains withal a sturdy British workingman, living a temperate and reasonable life. He is an exception to the general rule; but what is possible to one is open to many, and though we could not with equanimity contemplate the spectacle of numerous engineers' labourers bombarding the magazines with unsolicited contributions, we should rejoice to know that in the humblest walks of life as in the highest—and the need is equal in both—the pleasures of literature were rationally present.

It is with this ideal before us that the chapters which follow are penned.

HOW TO GET THE BEST OUT OF BOOKS

One point must be established at once. No one has a right to utter an opinion on any book who has not read many books systematically. The greater number of ordinary readers are totally unqualified to say whether a book is good or bad; while to aver that they like it or dislike it—however true the assertion—is an impertinence, since they have never troubled to develop the faculty of knowing how to judge. They know what they like or dislike; yes. Man Friday disliked salted food, but that did not prove salt a bad thing. The Patagonian was wont to eat his grandmother; but somehow the Briton has never considered that a toothsome dish. Similarly are many avid patrons of the circulating libraries Patagonians and Fridays, devouring with approval the things that offend all regulated tastes, or spitting out the real salt of literature.

It seems to us that to adopt the method, so commonly favoured by writers on this subject, of seasoning our advice with "elegant extracts" from celebrated authors, so that the resultant article is in great part a mosaic of mutually destructive opinions, is to perform no real service to the student. One recalls with bewilderment the conclusions of Bacon, Gibbon, Carlyle, Ruskin, Arnold, Johnson, Emerson, and a veritable multitude of counsellors more or less authoritative; and no good purpose is served by reviewing their opinions merely because they are their opinions.

The "Personal Equation" in Advice. We have steadily to allow for the "personal equation." Emerson's opinions were, no doubt, excellent—for Emerson. So with all the rest of them. We may content ourselves with a word or two on Emerson's: "Never read any book that is not a year old. Never read any but famed books. Never read any but what you like." This advice we must try to consider from the average man's point of view; and so regarded, it is the least wise counsel that could be offered by a great and wise mind. Plainly, it is useless to the average man. "Never to read a book that is not a year old." That is its soundest part; yet how unwise it is! A truly good book *may* appear this day; why wait a year before you bring your mind into touch with this new expression of a living mind? A year, if you like, before saying with decision that the new book is literature—will endure—but that is another matter. Nor is the vogue of a new book a wholly bad thing. To read what all others are reading has at least the merit of vivifying one's interest, though sober criticism may not come till later—a year later, if you will; years later. But deliberately to refrain from opening a book until it is a year old; no. Even the ephemeral in literature is not to be utterly despised; and we are persuaded that Hazlitt's oft-quoted advice as to reading an old book whenever a new one comes out is not to be taken as undervaluing all new literature, but as wise counsel not to allow the new books to crowd out the old and tried favourites.

Likes and Dislikes. "Never read any but famed books." Dubious advice, since so much depends on what is meant by "famed." "Don Quixote" is famed; "Gargantua," "Paradise Lost," "Pendennis"; so, too, "The Sorrows of Satan," "The Eternal City"—and these latter are more than a year old. "Famed," indeed! There is hardly any book, apart from trashy fiction and watery verse, that will not yield the intelligent reader some grain of knowledge, the more to be prized if separated from the chaff without the critics' guidance. There is much that is worth the reading in books that are not, and never will be, "famed," even in poor and mediocre books. As to never reading but what you like; that, too, is unwise counsel. Johnson said that "a man ought to read just as inclination leads him; for what he reads as a task will do him little good," which is a very different line of thought from Emerson's; though at first sight they seem parallel. For, as a matter of common experience, it is not the things we like that most stimulate our thoughts, but the things we dislike. The sheer pleasure of agreeing with another's thoughts tends for the time to make our own thinking a subjective faculty, if not entirely quiescent, whereas the man or the writer whose ideas disturb our equanimity, ruffle our temper, strike us rudely, will, while in no wise pleasing us, energise our own thoughts, rasp them, maybe, to smoothness and greater usefulness. It is conflict, not acquiescence, that produces activity, mental and physical; and the authors we dislike may have as much for us, if not more, than those we like. But—and here is the subtle difference between Emerson and Johnson—our "inclination" may lead us to bear company with an author we dislike, for the tonic effect of his opposing intellect. When we are conscious of this we may conclude we are reading to some profit.

The Right Way to Read. What we have to bear in mind about the "how" of reading is that there are many ways of getting the best out of a book, and that all are right. If the individual *feels* his own particular way to be right, it is right for *him*, though it might be the worst possible way for anyone else. The essential is, that he have a way; that he do not read aimlessly; that if he presume to utter an opinion on a book, he shall have deliberately come by that opinion as the result of a process of reason and study; that it be no capricious expression of an irresponsible mind. But, withal, it is still possible to indicate some rules which, modified in individual application, may reasonably be described as helps towards a practical system of reading.

Before Reading a Book. We have already pointed out that the reader must not come empty-handed to the author. We need not remark that he should know the rudiments of grammar and composition. It is necessary that he bring some quality, if it be only a conscious ignorance of the subject of study. But more usually he takes up a book already knowing something of the matter with which it deals, of the author's reputation, characteristics, previous works. Unless he is an aimless person he has also a reason for taking up a book; must have. That reason may be wise or mistaken; enough that it is a reason, that the reader is not merely bent on passing an idle hour.

Now, it happens often that the reading of one book leads to the reading of others by finding mention of them in the work just laid down. Thus, no one reading Boswell's voluminous "Life of Johnson," but has quite a host of other books therein suggested, the reading of which will be rendered (at the beginning, at least) the more piquant from knowing what Johnson thought of them. To be personal for a moment, we remember taking up "Moll Flanders," not after the same author's "Robinson Crusoe," but as the result of interest aroused in the book by Borrow's casual reference to it in "Lavengro." This was long before we could have shadowed forth any outline of a system in our own reading. It was a natural impulse, and any system is good that is based on natural tendencies, that methodises them. To note carefully the books which are mentioned as having been favourites with a man whose life we admire and would fain emulate, and to determine on a first-hand acquaintance with these, were an excellent feature of any system which the reader might evolve for himself from these and other hints.

Preparation for Reading. There are, of course, numerous reasons for reading a book, many of which are so obvious that we would but waste our space in defining them. Local interest will count for something; he is on safe ground who familiarises himself with all the notable writers identified with his town or district. If poets are chief of them, thus the reader may be led very pleasantly and far afield in the study of poetry. And it is well to have some one branch of literature, or even one author, that attracts us more than others, though never allowing this study to weaken our interest in general reading. The innate promptings of our nature must be permitted to influence us in following these by-paths of study; they will never take us astray if we are consciously in search of good.

Gibbon had a system of "self-examination" before reading any book, whereby he took stock of his own knowledge on the subject, glancing over the work to secure a rough idea of its scope before beginning seriously to study it. Thus he would know with precision how much the author had taught him when he had finished the reading of the book. Mr. John Morley has tried this method and commends it. It is, at least, one that depends upon no personal idiosyncrasy and is open to all. But we would urge a preliminary course, which is of great value and adds immensely to the pleasure of any book, supposing the reader to be only partially informed as to its writer. And that is, to turn up in any work of reference biographical particulars of the author; to furnish one's mind with the leading facts and criticisms concerning him and his writings, but *not yet* to read a full biography. Reference

should be made to more than one source of information, so that the reader may have before his mind's eye a rough sketch of the man and a brief outline of his work, before proceeding with the serious study of the book. Not until several books by the same author (provided his fame and achievement are not confined to one) have thus been studied, should his full biography be taken up.

When Reading a Book. We must never "skip" a preface. It is unfair to the author, foolish to ourselves, to omit hearing what he has to say in his preface. Overburdened as Scott's novels seem to be with prefaces and appendices, he is wise who reads them all; his grip of the romance will be far more enduring than that of the reader—and his name is legion—who boasts of always avoiding notes and introductions. If this is so in the case of fiction, it is still more so in the case of treatises in philosophy, science, travel, belles lettres. The preface is as much a part of the book as a door is part of a house.

Having read carefully the preface or introduction—sometimes we find both, and rarely, if it be a good book, without a reason—we begin the actual reading.

We have now to decide upon the qualities to observe in the work before us. These, of course, cannot be detailed in the present chapter, as each class of book presents different elements which will be specified in due course. But working examples must be given, and we shall take them from History and Fiction.

Things to Consider. In reading a historical work we have to consider (1) the author's point of view. The more picturesque and readable a historian is the more need is there to keep a sharp look-out for bias. We are pretty likely to find evidence of this, and whenever we suspect it we must refer to some other historians on the same point in order to correct our impressions; (2) the author's knowledge of men and motives, great movements, will call for examination, nothing being taken for granted unless it be an obvious statement of uncoloured fact; (3) his "style" will demand especial attention, as it is in a historian of equal importance with accuracy, and, indeed, his manner will largely determine his accuracy; one who is excessively fond of picturesque description and epigrammatic comment—Macaulay, for instance—being always open to the suspicion of letting his manner unduly colour his matter.

In a work of fiction we look for (1) a story. This is the first essential, and we have to ask ourselves whether it appeals to us as being an ingenious invention and credible. (2) Next we consider the sequence of the story. Is it unfolded naturally, inevitably? Are the events contrived as in actual life they might be? Or are they forced to fit the ends of the author? All these questions may be answered in the negative, although the first consideration be fully admitted. (3) Are the characters such as might exist in life, and do they act for just those reasons which would influence living people? Here, while (1) and (2) might be granted, (3) might be only partially allowed. (4) The vital question of "style," which includes humour, sympathy, method, personality, must be always, in some degree, present with the reader.

"Remember." There is no lack of touchstones—and we have indicated but a few—for the testing of a book, and just by the measure of the reader's *conscious testing* will he have profit of his study.

We cannot dwell on such details as the underlining of favourite pages or the keeping of a common-place book in which all thoughts arising from the study of a work will be entered and classified. But we must take occasion to say that few men have the temperament for the latter, and it is apt to render those who have, priggish and dependent in their opinions. Underlining, marginal notes, the jotting of references on the end papers, most readers do naturally, and with good results. But to *remember* is best of all, and it is as easy to write on the tablets of the memory as in a commonplace book, while it is infinitely more useful. Impressions written down are apt to be dismissed from one's mind by the very fact that the operation is intended to ease the mind of a burden, and commonplace books seldom yield their treasures at precisely the right moment, whereas the memory can be made to do so if properly cultivated. The things we remember are vastly more important in influencing the mind than those we dismiss into notebooks.

After Reading a Book. Having dealt with the preparation for and the actual progress of reading, some words on "after reading a book" may be looked for. But there is little advice of any practical value to offer, since all will now depend on the reader. When one has mastered the art of reading, he may be left to apply that to the best of his understanding. This may be said, however, that no reading of a book is complete until the reader has carefully reviewed the whole work in his mind, turned back to passages which may have puzzled him in the earlier parts and revised his first impressions in the light of his finished reading, as the end of a book, and especially of a work of fiction, may greatly modify the opinions formed in the earlier stages of its study. A good plan, if the book we have just read happens to be the first of that author's with which we have made acquaintance, is to take up some other of his writings, nor to allow the fact of its having displeased us to make us refrain from bearing him company a second or a third time. Indeed, it should be rather an incentive to our doing so, lest we allow ourselves, on the strength of one book, to form an erroneous opinion of any writer; for there is hardly any author—and few even among the giants—who has not produced one or more books which do not show him at his best. It is doubtful if we should ever set ourselves the task of reading in succession all the works of any one author, especially if he be as voluminous as Scott or Dickens. If the sequence be broken by turning to other writers, we shall be the better able to compare their styles, and so to appreciate all more accurately.

DRAWING AND DESIGN

A COMPLETE COURSE FOR ALL STUDENTS AND TECHNICAL WORKERS

INCLUDING

FREEHAND AND OBJECT DRAWING, PLANE AND SOLID GEOMETRY, LIGHT AND SHADE

AND COVERING TECHNICAL DRAWING FOR

Architects	Engineers	Plumbers	Coppersmiths	Lace Designers
Bricklayers	Joiners	Stonemasons	Tinmen	Cabinet Makers
Carpenters	Metal Workers	Textile Workers	Boilermakers	Wall Paper Designers

FOLLOWED BY A SECTION ON

THE ART AND THEORY OF DESIGN AND ITS APPLICATION IN MANY TRADES AND CRAFTS

CONDUCTED BY

Professor R. ELSEY SMITH, Lecturer on Architecture at King's College, University of London
WILLIAM R. COPE, Art Master at the Polytechnic School of Art, Regent Street, London
JOSEPH G. HORNER, Practical Engineer and Author of many Standard Engineering Works
PAUL G. KONODY, Past Master of the Junior Art Workers' Guild; and other experts

THE FIRST STAGES IN ELEMENTARY DRAWING

By William R. Cope

THIS course of drawing is intended for students who wish to become either artists, sculptors, designers, architects, engineers, cabinet makers, carpenters, or craftsmen of any kind, any one, indeed, who wishes to grasp the general principles of drawing will find the course adapted for him.

In the course is included freehand from the flat and the round, the principles of object drawing, geometrical drawing (plane, solid, and as applied to design,) brushwork, memory drawing, and light and shade. It forms a basis, therefore, upon which anyone can specialise for whatever career in the industrial arts or sciences he may wish to follow.

Drawing, the Universal Language. Drawing is a means of education, of training hand and eye; it quickens the powers of perception and gives scope to the inventive faculties. It trains the eye to accuracy and the mind to observation, attention, comparison, reflection, and judgment. It is the handmaid of all industrial art and science, and should be cultivated to the highest degree. It is a universal language, and the shortest of shorthands. How often it is found that some simple sketch explains very much more easily and quickly than dozens or even hundreds of words, some idea that one person wishes to convey to another! How an illustration helps to elucidate the text of a book we all know.

The term "drawing" is sometimes more particularly applied to the expression of form by line, such as is made with a pen, pencil, or other pointed instrument. But it is most important that a beginner should realise that there is no line in nature.

Nature's objects relieve themselves to the eye as spaces or masses that are lighter or darker in tone, or of colour varying with their surroundings. Consequently all expression of natural objects by line is a conventional rendering. Thus in 1 the form or space within the conventional line is separated from the surrounding part of the page, and suggests to us a flower; while in 2 we have the form or shape of the flower given in mass, without any line. It is merely dark relieved against light, or black varying with white. This *mass* drawing is much better for realising or suggesting the form of the flower.

Spaces and Lines. Almost every beginner thinks only of the turns and twists of the line, if drawing from a printed outline copy; or only of the edges if using an object for study. He is neglecting, of course, the most important part—the shape of the *space inside* the boundary line or edge. If we change two words in a well-known proverb, we get an excellent rule for drawing in any of its branches. This rule is—*take care of the spaces and the lines will take care of themselves.* The eye, in other words, must be trained to see *form*, and not merely lines and edges. By and by, the student will need to see *tone* and *colour* as well.

Many pupils find it much more pleasant to make drawings of cottages, trees, or living creatures; and unfortunately, some attempt to paint in colour, because it is so fascinating, before they know the elementary rudiments of drawing. Such misdirected efforts can only end in disaster. The work is out of proportion, the perspective is wrong, the tones and colour are false, and the performance, in fact, is lacking in most essential points. A drawing may be very neat, but if it does not give a *true* representation of the form of the object, it is of no value. Again, a picture may be carefully shaded, or even admirably coloured, but if the drawing is wrong the representation must be always unsatisfactory.

FREEHAND DRAWING.

Freehand drawing is drawing done without mathematical instruments. The materials required for it are some cartridge paper, an HB or B pencil, a sharp knife, a piece of good india-rubber, and (if the paper is not in the form of a book or a block) a drawing-board, half imperial size (22 in. by 15 in.), with some drawing pins. When more advanced, pen and ink or brush may be used. All these are now so cheap that there is no excuse for working with bad materials, thus creating unnecessary difficulties to be overcome. Then, too, some *good* copies of leaves, flowers, fruit, animals, common objects, and conventional ornament can be easily obtained. Natural leaves, flowers, shells, stuffed birds, &c., may be used to advantage as copies.

The illustrations in this course are not necessarily to be used as copies by the student. They are too small, and are used here for explaining the method to be adopted in learning to draw. The student must get copies for himself, see that they are carefully graduated in difficulty, and *practise* as much as possible.

The pencil should be sharpened as in 3 and not as in 4, and should be held lightly and at some distance from the point [3]. All sketch and block lines should be drawn lightly and freely, and not as if the purpose were to plough through the paper. A soft, grey, freely flowing line should be cultivated early, and not a hard, wiry, wobbly line.

Training the Eye to See. It is necessary that the student should keep well in mind that he must train his eye to *see* correctly, and his hand to give true expression, as artistically as he can, to what he sees. It is of little use putting down something and rubbing it out, continuing these processes perhaps half a dozen times until the drawing appears correct. There must be a definite impression in the mind before a line is drawn, and the pupil should endeavour to aim at the ideal of drawing every line correctly the *first* time. He should remember Ruskin's advice to the young man who asked how he should learn to draw. Ruskin sat down and looked for five minutes at the object for study. Then he drew one line. After another five minutes' careful observation, he drew another line, and said to the young man: "That is my advice to you on how to learn to draw." Slow, tedious work, some will say, but *so* slow and tedious is learning to play the scales in music. Ruskin meant that the student must learn to *see* before he could hope to draw, and correct sight cannot be achieved by a superficial glance.

Study the Copy. This training of the eye must be persevered with assiduously. Through all stages, in order to render the pupil capable of judging more complex things in his advanced studies—such as the subtle changes of light and shade, and the beautiful variations of colour in nature—the student must persevere in the close attention to detail and training of his observation. His judgment will be more certain, and he will find more pleasure in his work.

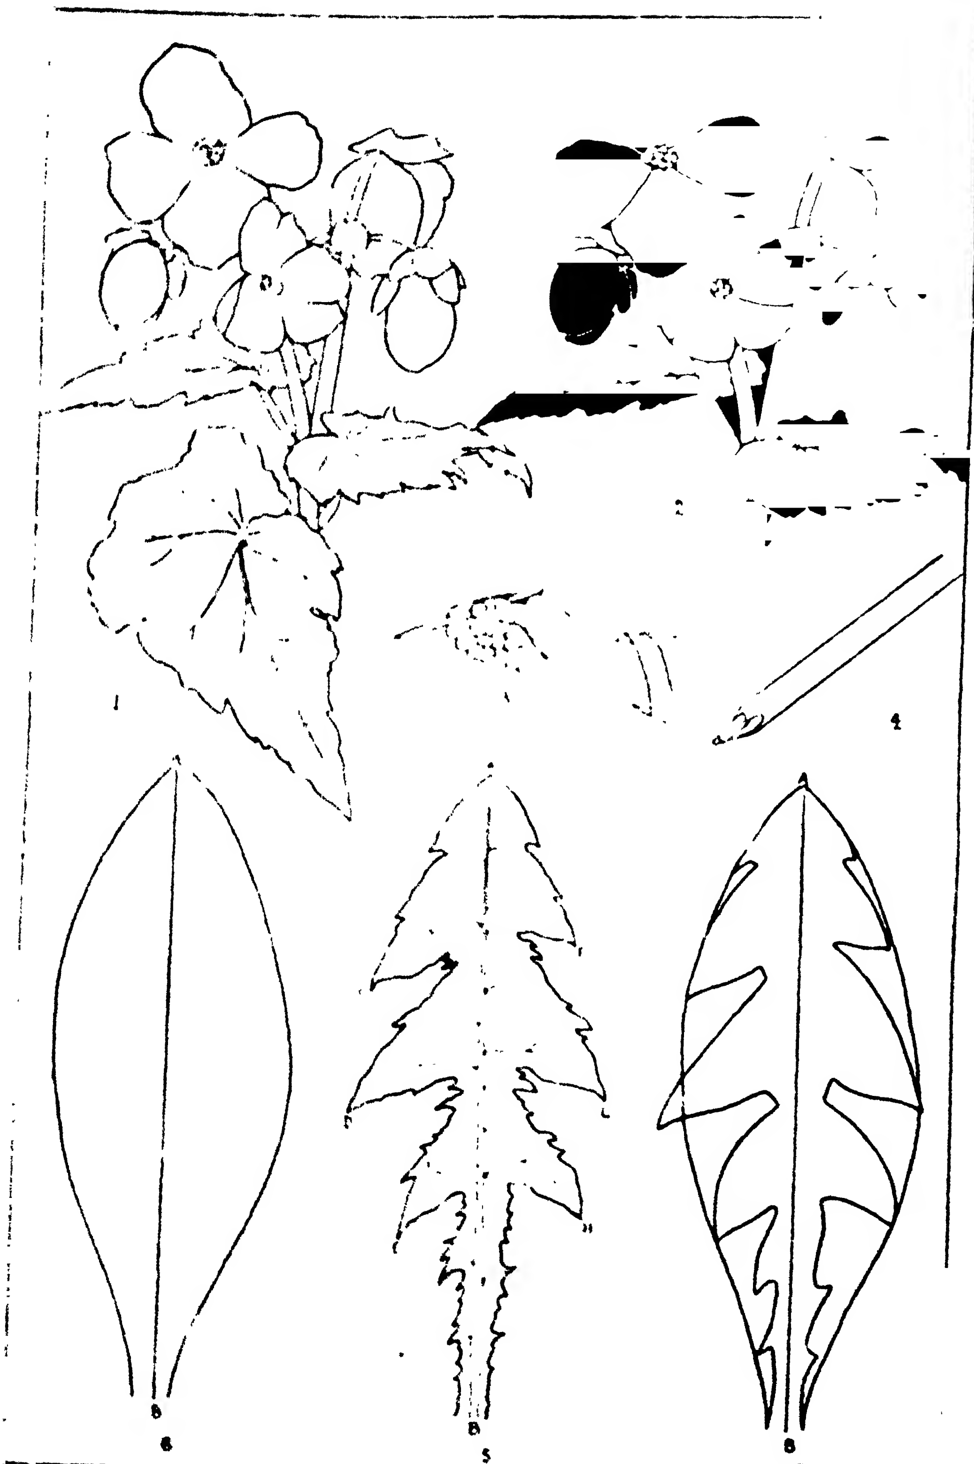
At the outset, therefore, he should carefully observe the main general proportions of the copy or object of study—how it is placed in its surroundings, its leading growth lines and masses, the peculiar growth of the plant, the pose and action of the animal. He should not trouble at first about details, but should get the main facts correctly impressed upon his mind.

Let us take now a dandelion leaf for study [5]. Let it be pinned flat on a card or board, for the sake of more readily observing it carefully and intelligently.

Some Main Points to Note. First note the general proportion between height or length, AB, and width, DG. At first glance the student will probably think the width is considerably less than half the length, but he would have been deceived by the numerous deep serrations. If a steadily curving line were drawn almost exactly through the points A, C, D, E, and another through A, F, G, H, he will see a shape as indicated in 6. It will now be observed that the width, DG, is very little less than half the length, AB. The points D and G are about equidistant from A and B; also E is equidistant from A and G, whereas C, nearer D than to A. Again, the space CF is smaller than DG. The distance GH is about one third of GB, but DE is more than one third of DB, and EH is rather less than CF. The student must endeavour to judge these proportions first with the eye alone, and then test his judgment by measuring. *On no account must he measure with a pencil or ruler first.* This would be easier and quicker, and certainly the result would be quite correct, but he must remember that he must train the eye to *see*. Judgment with the eye alone will, of course, be more or less inaccurate at first, and the work will seem slow and tedious, but this method must be persevered with if true progress is to be made. Each time the student will succeed more and more, until he will become surprised by the way in which he can *see* the true proportions.

Features to Observe. Next direct the attention to the three peculiarly shaped lobes on each side, with the deep serrations between, noticing that one of the three lobes on each side is the largest, and a subtle gradation in the size of the others. The downward direction of the characteristically shaped "teeth," from which the plant gets its name (dent de lion), the gradually thickening midrib, with its secondary branching veins, and the way in which they grow from it, should also be noted. Another important feature is the tendency of the side veins to run down towards the base of the leaf, as generally happens. These veins are also nearer the lower edge of each lobe. This thorough investigation shows what a great deal would be missed in a superficial glance, and that there is method and regularity underlying apparently irregular forms. Observe also, the decorative effect of the whole leaf.

Having now stored the mind with many facts, begin by drawing a central line AB, and the two curved lines [6]—*block* lines, they are called—rigidly keeping the relative proportion previously observed. Block in the large lobes in their true proportions, carefully noting how



THE DIFFERENCE BETWEEN LINE AND MASS, WITH A FIRST LESSON IN DRAWING.

far the main serrations go in towards the mid-rib, and leave out the smaller serrations [7]. Now put in the largest secondary veins, keeping all lines faint yet visible, so that comparison can be made between the drawing and the leaf, and discrepancies corrected. Alterations can always be made more easily and quickly at this stage, with only simple block lines to deal with, than when the details are filled in. It would be best not to sketch in details at all now, but to draw them direct in the finishing stage, when they are more likely to have the desired expression which rarely or never comes at first.

Finishing. If all appears so far correct, partially rub out block lines, and finish with a neat, fluent, and expressive line, not necessarily one that is all the same thickness. The lines for the edges might be stronger than those for the veins. There might, in fact, be varying degrees of thickness used at discretion. Do not forget in this finishing stage to very closely observe the natural leaf, in order to get true representation, and be especially careful to note the characteristic shape of teeth and serrations. The finished drawing should now be like **5** in proportion and shape of details, but the line should be more expressive and more artistic than can be rendered by a printed line. A really artistic hand-drawn line must always be more beautiful and expressive than a printed one, for there cannot well be artistic feeling in a machine.

The student should get other leaves or flowers, such as **8**, **9**, and **10**, and go through the same process of observation in every case before beginning to draw, always trying to develop his perceptive faculties.

For further explanation of the method of learning to draw we will take a copy like **11**. This is absolutely symmetrical, and is a piece of ornament founded on the honeysuckle (*anthemion*) and acanthus leaf. Observe that, although the design is conventional, there is suggested a system of growth and radiation from point B, and that the design has a sense of unity, vigour, and stability, as well as a beautiful and subtle gradation in the size of subordinate parts. Though certain forms are repeated many times, there is no suggestion of monotony. This study of the artistic side of a copy or object must be cultivated as soon as possible, not merely to add interest to the work but to increase the powers of perceiving the beautiful.

The Straight Line. On the practical side is an upper (*anthemion*) and a lower (*acanthus*) portion. The greatest width, CD, is very nearly four-fifths of the height AB, and the spaces HK, KF, FL, etc., are nearly equal. Draw first the central line AB, say, about eight or nine inches long, so as to make a good-sized drawing. It is much better not to draw on a small scale, because freedom of pencil movement should be cultivated, and a better exercise in judging proportion can be made with a drawing of moderate scale. Do not rule construction lines, but practise pure freehand drawing. When drawing the line AB be careful to keep it quite vertical, otherwise the drawing, when finished, will appear to be falling over, thus destroying the stability observed in the copy.

One of our living artists has said that not more than one person in a hundred can draw upright lines freehand. This is quite true among beginners in drawing, because, through want of thought, they do not sit properly in front of their drawing paper, or they unconsciously turn the paper cornerwise. The uprightness of the leading growth line AB ought to be judged at the start by noticing whether it is parallel to the right and left hand edges of the paper.

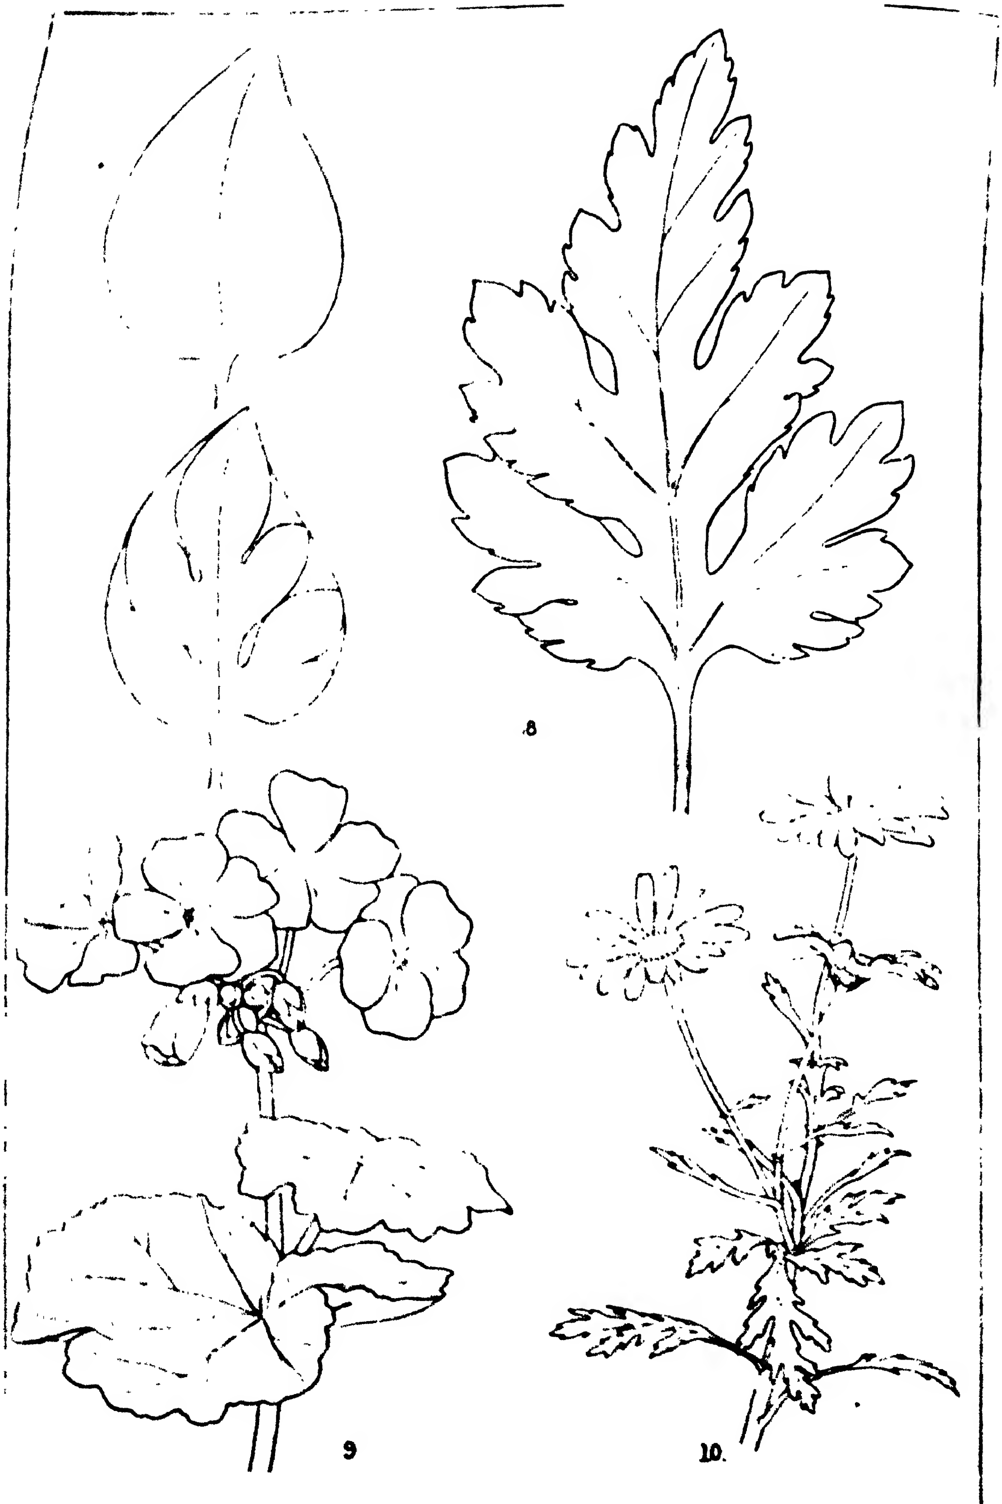
Having drawn AB correctly, do not draw a lot of horizontal lines, say, HN, KO, FG, etc., which would be getting merely mechanical accuracy and confusing the work with unnecessary lines. Determine the greatest width CD by lightly marking where the points C and D should be, being careful as to how far down they must come. Next mark the position of F and G, observing that the space FG is four-fifths of CD, and about midway between A and E. Then draw lightly and freely the block lines of the large masses indicated in **12**. Afterwards draw the leading growth lines, and the secondary block lines [**13**], observing carefully all the time the relative proportions of the spaces between them.

At this stage, again, compare the sketch with the original, and correct any mistakes. Nearly rub out the construction lines, note the peculiar shape of the serrations of the acanthus leaf, and the tangential junction of neighbouring lines of honeysuckle, and finish with a good fluent line.

The Help of Museums. The student should continue practising similar copies graduated in difficulty. He might also study from casts of ornament, or from real sculpture in relief, or from woodcarving. Many fine specimens are found in museums, churches, and any interesting old buildings. A sketch book should be carried in readiness for sketching any rare and beautiful piece of ornament, which may be useful for reference and give facility for practice.

Almost everybody has a wish to be able to draw beasts and birds, and by this time the student should be able to draw them from good flat copies, or better still, from the stuffed examples in museums, which make excellent studies if placed so as to get a profile view; otherwise placed there is too much difficulty at first with foreshortening, a subject we shall come to in dealing with object-drawing. The method to follow in such studies is similar to that to be pursued in securing general proportion of masses and block lines, although the latter should be more frequently *straight* ones. The pupil, however, must assiduously seek for the pose and action of the creature.

A New Field for Perception. Take, for example, a study of the crow, as in **14**. Observe the general proportions and note the pose and action of the bird—that it is bending down as if to peck up something, its legs in a characteristic attitude to enable it to do so, one stretched forward and the other partly raised



SUGGESTED STUDIES IN CHRYSANTHEMUM LEAF, GERANIUM, AND MARGUERITE

as if the bird were stepping forward. There is time to study all these things with the printed copy before us, but in the study of the living creature the pose or action is momentary, and only keen and rapid observation is of any avail.

This opens a new field in which the student should continue the development of his faculties of perception. Let him study all kinds of living creatures in action, and either mentally or in his sketch-book—or, better still, in both—jot down each main characteristic line expressing the action.

Drawing from Life. The first block lines for the study of the crow should be as in **15**, the chief observations concerning the relative proportions, pose and action. It will be seen that these block lines are chiefly straight; this is to obtain more vigour, real expression, and a suggestion of the anatomy of the bird in the finished drawing.

It will, moreover, enable the student to develop a good system by which, when he arrives at a more advanced stage, he can draw the human figure or any living creature in any position. Proceed with the next stage as indicated in **16**, clean up with the rubber, and finally draw with as expressive and artistic a line as possible, putting in any necessary details direct. The lines in such a study, as in studies of leaves and flowers, need not be all of one thickness, but should vary, giving strength to those lines which need it. A single stroke, even, need not be of the same thickness throughout. The lines, too, may be more broken, yet in such a way that there is no confusion, but the true representation of form or mass.

Well drawn representations of butterflies, shells, and fish will make good copies, but it would be much better if the objects themselves could be obtained and used as studies.

Pen and Ink. As considerable progress in drawing with lead pencil ought to have now been made, it will be useful to make freehand studies with pen and ink. The materials required can be obtained at such little cost, and of such good manufacture, that the student need only be careful in the selection of them, in order to provide himself with very satisfactory materials. Artists' black or liquid Indian ink are the best inks, and the pen should be flexible, so that varying thicknesses of lines may be obtained easily and quickly. As regards paper, cartridge has too soft a surface to give very good results. It is best to purchase some *hot pressed* Whatman's or Old Water Colour Society's paper, or better still, some Bristol boards.

In beginning to draw, sketch first with lead pencil the leading growth and block lines in true proportion, and then, without any preliminary sketching of details in pencil, proceed to finish with pen and ink, holding the pen so that perfect freedom of movement in any direction, and different thicknesses of line, may easily be obtained. Make all the lines as expressive as possible. The student should make frequent study of the pen-and-ink work of celebrated men. He will often find good examples in the illustrations of books by Walter Crane, Sir John Tenniel, Sir John Millais, and many other artists of our time. Among the older masters, Durer and Holbein may be mentioned, and, although their work is not all pure pen and ink drawing, much may be learnt from them about expression of line.

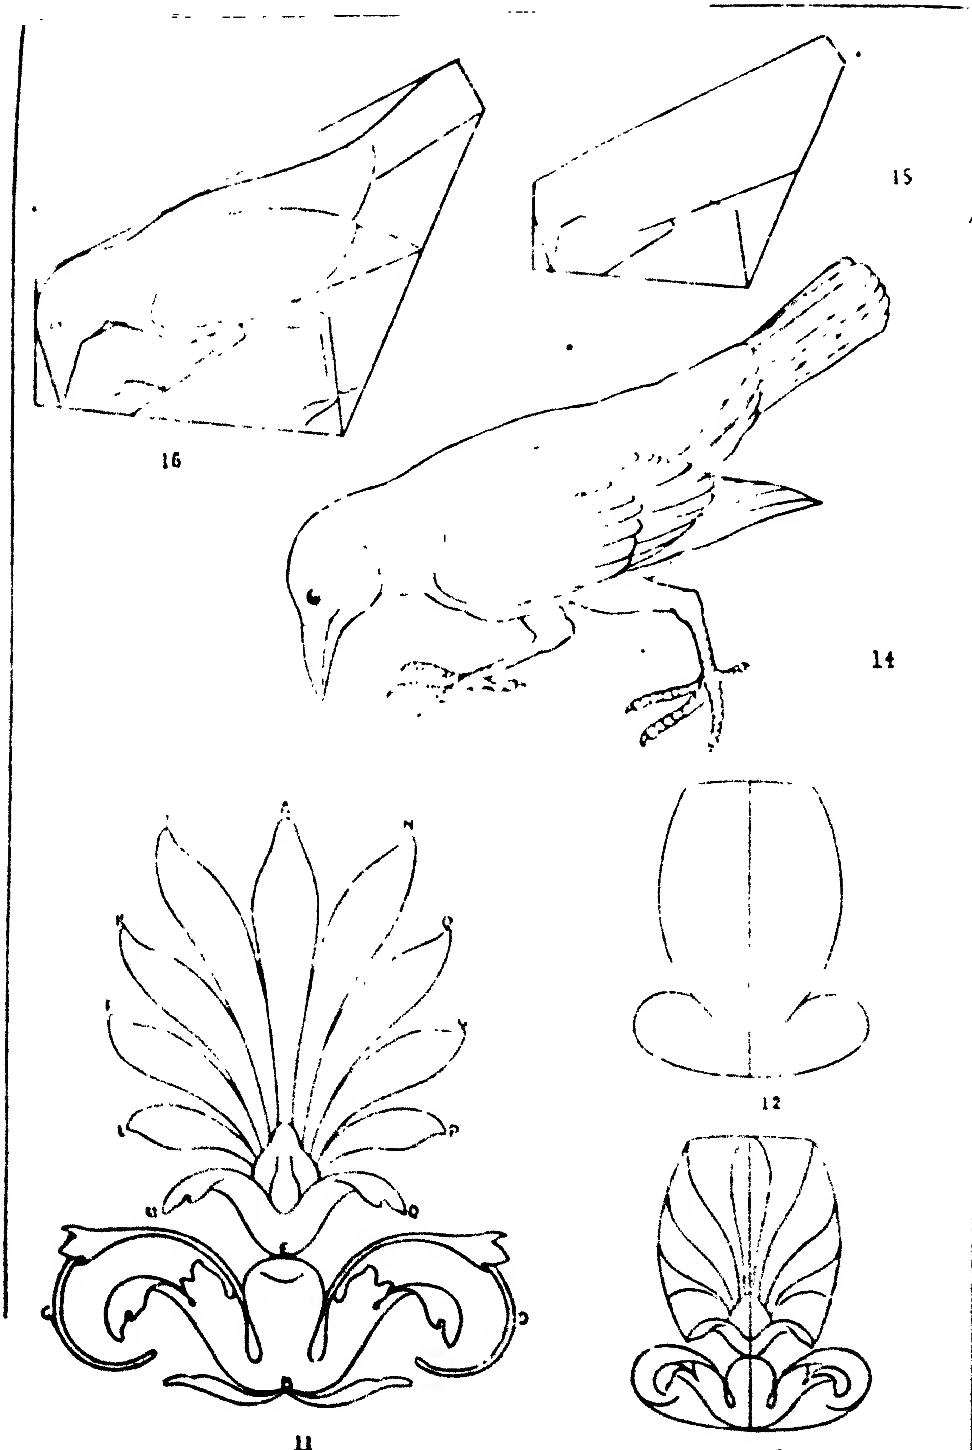
JAPANESE BRUSH DRAWING.

An Exact Impression in the Mind. It is good practice to draw direct with pen and ink without *any* pencil construction lines. This still further develops the student's powers of perception, because, knowing that he cannot easily rub out ink lines, he is the more careful to form a definite impression before drawing a single line.

Line drawing with a brush and Indian ink, sepia, is another good exercise. The brush is so flexible that many things can be expressed by it better than with pen or pencil. The brush should be a sable "writer," and not too small. To learn what may be done with a brush in line drawing, the pupil should study the many fine examples of Japanese work, in which great charm and skill are displayed. [See example on this page.]

If the student has steadily persevered, in spite of difficulties and disappointments, through the course we have taken together, he will have realised how exceedingly important it is to follow the advice about an intelligent, searching observation of the whole object before he begins to draw. He must have in his mind an exact and clear impression before he can have any hope of transferring truth to paper.

To be continued



ORNAMENTAL DRAWING: STUDY OF A CROW, HONEYSUCKLE, AND ACANTHUS.

LANGUAGES

FIVE GREAT LIVING LANGUAGES OF EUROPE

BEING

COMPLETE COURSES IN ENGLISH, FRENCH, GERMAN, SPANISH AND ITALIAN

TOGETHER WITH

A SIMPLIFIED SYSTEM OF LATIN, AND AN INTRODUCTION TO THE STUDY OF LANGUAGES

TAUGHT BY

LATIN & ENGLISH } GERALD K. HIBBERT, Master of Arts of Oxford University; Bachelor of Arts of London; Classical Master at Broadgate School, Nottingham.

FRENCH—LOUIS A. BARBÉ, B.A., French Master at Glasgow Academy.

GERMAN—P. G. KONODY, Anglo-Austrian Littérateur, and Dr. OSTEN, Dramatist.

SPANISH—Madame de ALBERTI, Teacher of Spanish in London.

ITALIAN—FRANCESCO DE FEO, Teacher of Italian in London Schools.

AN INTRODUCTORY NOTE ON THE STUDY OF LANGUAGES

LANGUAGE, or Speech, is the expression of thought by means of words.

Words are combinations of elementary sounds, to which a certain meaning is attached. The meaning of a word is what is thought of when the word is used.

A language is a collection of all the words used by people who understand one another's sounds. It cannot be too strongly emphasised that the words used by a certain people or nation, and the meanings attached thereto, are purely arbitrary—that is to say, each nation chooses for itself what words it will use, and determines what those words shall mean. For example, we in England call our staple food "bread," while the French call it *pain*. There is, of course, a *reason* for using these words ("bread" being derived from a Teutonic root, which also gives the German *brot*, and *pain* coming down from the Latin *panis* = bread), but in the beginning it was perfectly optional for our forefathers to have called bread "gypsum" or "chaw-chaw," or any other sound or combination of sounds that their fancy suggested.

Words are generally used in groups called *sentences*. A sentence is an expression of a complete thought, as "We know"; "To be or not to be; that is the question."

Grammar. The rules for grouping words in sentences are called *Grammar*. Grammar, therefore, may be defined as the science that treats of language. English grammar, French grammar, Latin grammar, and all other gammars, are those portions of the general science of language which treat of the speech of the English, French, Latin, and all o her. peoples. As with words, so with grammar; each nation settles its own. Changes of language are all decided on deliberately, though no one can say how they arise. Why, for example, does an Englishman say, "I have misunderstood it," whereas according to French grammar he would say, "I it have misunderstood"; and according to German, "I have it misunderstood"?

In writing, we represent to the eye the elementary sounds forming words, by means of marks or symbols, called letters. Each letter is the symbol of a certain sound, so that the reader, on seeing the symbol, makes the sound. Here, too, as in speaking, a nation settles for itself what letters it will use, and of what sound each letter shall be the symbol.

Words and Sentences. The grammar of any language falls naturally into two parts: *first*, that which deals with separate words; *second*, that which deals with words combined to form sentences. The first division is called *Etymology* [Greek, *etymos*, meaning "true," and *logos*, meaning "statement"]. It treats of the variations of form which words undergo to mark changes in their relations to other words, and of the manner in which they are formed out of simpler elements. There are thus two distinct branches of etymology: (*a*) the part of grammar that deals with inflexions of words; (*b*) the investigation of the derivation and origin of words. The name of *Accidence* is often given to branch *a*, either because it shows what changes may befall words [Latin, *accidere*, to befall], or because these changes are "accidentals" of words and not essentials.

The second main division of grammar, dealing with words combined in sentences, is called *Syntax* [Greek, *syntaxis*, arrangement]. The rules of syntax are statements of the ways in which the words of a sentence are related to each other. Syntax deals both with the order of words in a sentence and with the particular inflexions required in any given sentence to produce the desired meaning.

Classification of Words. The different classes in which words may be arranged are called Parts of Speech. These are the same in all languages. The English names for the eight Parts of Speech are as follow—[note that these

names are all derived from the Latin equivalents.)

1. A *Noun* (*nomen*, name) is a word used as the name of something—*e.g.* bird, *avis* (Latin), *oiseau* (French); James, Jacques.
2. An *Adjective* (*adjectivus*—that may be joined to) is a word used with a noun to describe, to measure, to count, or to indicate that for which the noun stands—*e.g. hot* days, *four* boys, *this* man.
3. A *Pronoun* (*pro*—instead of) is a word used instead of, or to avoid repeating, a noun—*e.g.* "When Elizabeth died, *she* was seventy years old."
4. A *Verb* (*verbum* = word) is a word by means of which we state something—"Birds *sing*."
5. An *Adverb* (*ad verbum* = to a word) is a word which shows how an action, state, or quality is modified or limited—"He speaks *eloquently*."
6. A *Preposition* (*prae positus*—placed before) is a word which shows how things, or their actions and attributes, are related to other things—"The Mill *on* the Floss"; "Come *unto* Me." It is usually "placed before" the noun which it governs.
7. A *Conjunction* (*con-junctio*—joining together) is a word which joins together words or sentences—*e.g.* "Man proposes, *but* God disposes"; "Come buy wine *and* milk."
8. An *Interjection* (*inter-jectus*—thrown between) is a word "thrown in" to express some feeling or emotion. It has no grammatical relation to the sentence in which it stands: "Alas!"; "Hurrah!"

The above is the usual classification: but according to derivation there are really only *three* Parts of Speech—Interjection, Verb, and Noun. For the Noun, strictly speaking, includes Adverb, Preposition, and Conjunction (which are old or disguised cases of nouns), Pronoun, Adjective, and the Infinitive Mood and Participles.

Inflexion (Latin, *inflectere* = to bend) is a change made in the form of a word to denote a modification of meaning, or to show the relationship of the word to some other word in the sentence.

Nouns and pronouns are inflected to mark Number, Gender, and Case. This inflexion is called *Declension*. Thus, in Latin there are five declensions, in Greek three, in German the Strong and the Weak declensions, etc. The old grammarians used to speak of the subject (or nominative case) as the "upright" noun, and all the other cases as "oblique."

Case. The word *Case* means "a falling," and the oblique cases were conceived of as falling away or "declining" from the nominative. Hence the declension of a noun is a statement of its cases—*i.e.* of the forms which it assumes in various relations. The full number of cases is seven.

Nominative (including the Nominative of Address, sometimes called the Vocative).
Accusative (the case of the direct object).
Dative (the case of the indirect object—*e.g.* "I give *him* a book").
Genitive (the case denoting origin or possession).
Ablative (the case denoting separation from).
Locative (the case denoting place at which).
Instrumental (the case denoting association with).

The last two became merged in the ablative in Latin, while Greek has lost both these and the ablative.

Gender. The distinction between male and female in nature is called sex. The distinction between Masculine and Feminine in words is called *Gender*. In English we adopt the natural distinctions of gender: names of animals of the male sex are masculine, names of animals of the female sex are feminine, names applied to animals of either sex are common, and names of things of neither sex are neuter. This is perfectly simple, but other languages, such as Latin, French, and German, often distinguish the gender of nouns by their endings, irrespective of meaning; thus, in German, *Madchen* = a little maid, is neuter; and in French, *la table* = the table, is feminine.

Number. Number is the difference in words to express one or more than one—singular or plural.

Comparison. Adjectives and adverbs are inflected to mark degree. This inflexion is called *Comparison*. There are three degrees of Comparison—*Positive, Comparative, Superlative*. A Positive adjective compares a thing with all other things, and ascribes to it a certain quality—*e.g.* long, *beau* (French), *altus* (Latin). A Comparative adjective compares the thing named with one other, and shows that the first has more of a certain quality than the second—*e.g* longer, *plus beau, altior*. A Superlative adjective compares the thing named with several others—at least two—and shows that it possesses a certain quality in a higher degree than any of the others—*e.g.* longest, *le plus beau, altissimus*. The same applies to adverbs.

Conjugation. Verbs are inflected to mark Voice, Mood, Tense, Number, and Person. This inflexion is called *Conjugation*. Voice is the form of the verb by which it is shown whether the subject of the sentence stands for the doer or for the sufferer of the action spoken of by the verb. Most languages have two voices—Active (where the subject of the sentence is the doer of the action), and Passive (where the subject of the sentence "suffers," or is the object of the action). Greek has a Middle or Reflexive Voice in addition. Mood is that variation of the verb used to express the mode or manner of an action or of a state of being, *e.g.* simple statement (Indicative Mood), command (Imperative), possibility (Subjunctive). When a verb has no subject expressed or implied, it is said to be in the Infinitive Mood; the other moods are finite. Tense indicates the time to which an action or event is referred; in all languages the natural

division is into Past, Present, and Future, with different varieties and shades of meanings of each. Person is a modification of the form of a verb by which it is shown whether the speaker speaks of himself (First Person), or of the person or persons addressed (Second Person), or of some other person or thing (Third Person). To "conjugate" a verb is to give all its tenses and moods, and the full Conjugation of a verb is the formation of all the inflexions and combinations used to indicate Voice, Mood, Tense, Number and Person. Thus, when we speak of the four Conjugations in Latin or French, we mean the four modes of forming the tenses in those languages. In English there are two "conjugations," Strong and Weak: the former modify the vowel-sound of the root to form the past tense (write, wrote); the latter add *-ed* or *t* to the stem (*love, lov-ed*).

Prepositions, Conjunctions, and Interjections are not inflected.

Root. These inflexions are not peculiar to English: they are found in Latin and Greek, and most of the modern European languages. Originally most words were constructed on one and the same plan. There was first of all a syllable or short combination of sounds, called a *Root*. The root is that portion of a word which it has in common with other words that relate to the same notion; it represents some fundamental idea common to many words, as GEN in *genesis, genitive, generation, gender, genus*. To the root was added a suffix or suffixes, indicating the part of speech intended, as *th* in *length*. The root and this suffix combined form the *Stem*; the stem, therefore, of a word that admits of inflexion, is that portion of the word on which the inflexions are based. This suffix is often called a stem-suffix, to distinguish it from the later suffixes appended to mark change of number, case, tense, etc., as *-s* in *boys, girls*; *-'s* in *boy's, girl's*; *-ed* in *loved*, etc.

Thus we have first the root, then the stem, finally the complete inflected word: *e.g. na* (root), *nature* (stem = root + suffix *-ture*), *natures* (stem + plural inflexion).

Analytic and Synthetic Languages. We are now in a position to understand one of the deep-lying fundamental divisions between languages. A language which is rich in inflexions, like Latin or Greek, is called *Synthetic* (Greek, "syntheticos" = "able to put together"), because it puts many meanings and relations into one word. A language which is poor in inflexions, like English or French, and uses separate words instead, is called *Analytic* (Greek, "Analyticos" = able to split up or take to pieces: *cf.* the noun "analysis").

The tendency of languages is to pass from Synthetic to Analytic, and the languages which are to-day Analytic were originally far more Synthetic, if not entirely so. We see this tendency in the passage from Latin to French, and in that from Anglo-Saxon to modern English. Anglo-Saxon, for example, was an Inflexional or Synthetic language: its nouns had five cases, and there were different declensions; adjectives were declined, and had three genders; pronouns had more forms than they have to-day, and some had a dual number, as well as a singular and plural; the verbs had more variety in the terminations of their persons. Gradually, in the three centuries following the Norman Conquest, most of these inflexions were dropped, and separate words (such as prepositions and auxiliary verbs) were used in their stead. For example, the Anglo-Saxon word "Tunge" (= tongue) was declined thus:

Case.		*Singular.*	*Plural*
Nominative	...	Tunge	Tungan
Accusative	...	Tungan	..
Genitive	.....	..	Tungena
Dative	.....	..	Tungum
Ablative	.	..	..

Prepositions. Modern English, however, marks these inflexions by the use of prepositions, *e.g.* "of the tongue," "to the tongue," etc. Similarly in Latin, for example, the different persons, numbers, tenses, moods, and voices were denoted by inflexions: *e.g. amo* (I love = *j'aime*), *amas* (thou lovest = *tu aimes*), *amat* (he loves = *il aime*). Latin, *amaretur* (he would be loved): the root is *am* (love), *a* is a stem-suffix, marking a verb; *re* denotes subjunctive mood and past tense; *t* third person, and *ur* passive voice.

The few inflexions that English does keep are all derived from Anglo-Saxon, *e.g. why* (the old ablative or instrumental case of *who*), *whilom* and *seldom* (the old dative cases plural of *whil* = time, and *seld* = rare). Probably in course of time English will become still more and more Analytic, until perhaps some day it will be an inflexionless language.

How best to Acquire a Language. There is no short cut to the acquisition of a language, that is, to the thorough understanding of it. Of course, a language can be very easily "picked up," as we say, by a short residence among the people who speak it. But merely to repeat certain sounds is not to know a language, even if we pronounce the sounds quite correctly. To know a language we must understand the why and the wherefore of all the inflexions of its words, and their relationship one with another in any sentence of that language.

Undoubtedly, therefore, the best way to *study* a language and to learn its grammar is to begin with sentences, not with single words. The unit of speech is the sentence, and we cannot fix an exact meaning to a word until we see it in a sentence. It is thus a great mistake to start learning the grammar of a language by committing to memory pages of rules and paradigms, or by confining oneself entirely to acquiring a large vocabulary of its words. It is with the sentence that the pupil should begin. When once a sufficient number of sentences has been "assimilated," it will be easy to analyse them into their component parts, and to show the relations that these bear to one another. "In this way," says Prof. Sayce, "the learner will be prevented from regarding grammar as a piece of dead mechanism or a Chinese

puzzle, of which the parts must be fitted together in accordance with certain artificial rules, and will realise that it is a living organism which has a history and a reason of its own. The method of nature and science alike is analytic; and if we would learn a foreign language properly we must learn it as we did our mother tongue, by first mastering the expression of a complete thought, and then breaking up this expression into its several elements."

The Parent of Modern Languages. The more languages one knows, the easier it becomes to acquire others; for the student of several tongues is able to "link on" the new one with the old. To a student of Latin, for example, the acquisition of French is a simple matter; he knows that in Latin *bene dormire* means "to sleep well"; so when in French he meets the words *bien dormir* he knows their meaning at once. Thus an enormous amount of memory-work is saved, and learning becomes not so much a "getting something off by heart," as a pigeon-holing of new ideas and impressions into receptacles already prepared for them. The question is often asked, "Of what use is the knowledge of Latin?" Seeing that Latin is the parent of French, Italian, Spanish, etc., and has also enormously influenced the English language, it will be easily seen that to know Latin is to accelerate the pace at which one can earn any of these languages.

LATIN

By Gerald K. Hibbert, M.A.

BEFORE beginning this course, the student should read carefully the article on the study of Languages which introduces this Section of the EDUCATOR. The student is recommended also to use a good English Latin and Latin English Dictionary.

Alphabet. The Latin Alphabet is like the English, but Latin has no "w."

Pronunciation. As Latin is a "dead" language, its pronunciation is comparatively unimportant. In our Universities and Public Schools it is usually pronounced as English. It is more correct, however, to pronounce it as French or Italian. Thus, for example:

a should be pronounced as ah (as in father).
e „ „ a (as in pay).
i „ „ e (as in meet).

It matters little which pronunciation the student adopts.

Stops and Spelling. Latin is spelt by *syllables*, as English. The Quantity of Syllables is short (˘), long (¯), or doubtful (˘̄), as the vowels are long, short, or doubtful.

The modern *Stops* are used in Latin.

FIRST LESSON

SECTION I. GRAMMAR

There are Five Declensions of Latin Nouns, known by the endings of their Genitives:

Gen. Singular — æ, i, is, ûs, ei.

Gen. Plural — Arum, Orum, Um or Ium, Uum, Erum.

Nouns are declined by Number and Case; Adjectives by Number, Case, and Gender.

The *Numbers* are two: Singular and Plural.

The *Genders* are three: Masculine, Feminine, and Neuter. In Latin the gender of a noun is often determined by its ending, not, as in English, by its meaning. Thus, *mensa* = a table, is feminine, although "table" is neuter in English.

The *Cases* are six:

		Answers the question—
1.	*Nom.*	Who or what?
2.	*Voc.*	(Case of the person addressed.)
3.	*Accus.*	Whom or what?
4.	*Gen.*	Whose or whereof?
5.	*Dat.*	To or for whom or what?
6.	*Abl.*	By, with, or from whom or what?

NOTE: The dative and ablative plural are always the same.

Nouns: First Declension: *-a* stems.

Nominative case ends in *-a*, except a few in *-as* and *-es*. Nearly all nouns ending in *-a* are of feminine gender. No neuters in this declension.

Singular.

Nom. (or subject)	mensa, *a table.*
Voc.	mensa, *O table.*
Accus. (or objective).	mensam, *a table.*
Gen.	mensæ, *of a table.*
Dat.	mensæ, *to or for a table.*
Abl.	mensā, *by, with, or from a table.*

Plural.

Nom.	mensæ, *tables.*
Voc.	mensæ, *O tables.*
Accus.	mensas, *tables.*
Gen.	mensarum, *of tables.*
Dat.	mensis, *to or for tables.*
Abl.	mensis, *by, with, or from tables.*

Use the accusative where in English we use the direct object, and the dative where we use the indirect object—*e.g.*, he gives a book (accus.) to the boy (dat.).

Like *mensa* decline almost all nouns ending in *-a*, except that *dea* (goddess) and *filia* (daughter) make dative and ablative plural *deabus* and *filiabus* (to distinguish them from the dative and ablative plural of *deus* = god, and *filius* = son).

Nouns: Second Declension: *-o* stems.

Nominative ends in *-us* and *-er* (usually masculine), or in *-um* (neuter).

	Singular.	*Plural.*
Nom.	animus (*the mind*).	animi
Voc.	anime	animi
Acc.	animum	animos
Gen.	animi	animorum
Dat.	animo	animis
Abl.	animo	animis

	Singular.	*Plural.*
Nom.	puer (*boy*)	pueri
Voc.	puer	pueri
Acc.	puerum	pueros
Gen.	pueri	puerorum
Dat.	puero	pueris
Abl.	puero	pueris
Nom.	faber (*workman*)	fabri
Voc.	faber	fabri
Acc.	fabrum	fabros
Gen.	fabri	fabrorum
Dat.	fabro	fabris
Abl.	fabro	fabris
Nom.	donum (*gift*)	dona
Voc.	donum	dona
Acc.	donum	dona
Gen.	doni	donorum
Dat.	dono	donis
Abl.	dono	donis

NOTE: The vocative of *Deus* (God) is *Deus*: nominative plural, *Di*; dative and ablative plural, *Dis*. The vocative of *filius* (son) is *fili*. *Vir* (a man) is declined like *puer*; accusative, *virum*; genitive, *viri*; dative and ablative, *viro*.

Adjectives: First and Second Declensions. Adjectives of three endings in *us, a, um* (masculine, feminine, neuter) or *er, a, um*, follow the Second and First declensions of nouns. Decline the masculine like *animus*, *puer*, or *faber*; the feminine like *mensa*; the neuter like *donum*. Thus, *bonus* (good):

	Masc.	*Fem.*	*Neut.*
Nom.	bonus	bona	bonum
Voc.	bone	bona	bonum
Acc.	bonum	bonam	bonum, *etc.*

Also:

Nom.	tener (*tender*)	tenera	tenerum
Voc.	tener	tenera	tenerum
Acc.	tenerum	teneram	tenerum, *etc.*
Nom.	niger (*black*)	nigra	nigrum
Voc.	niger	nigra	nigrum
Acc.	nigrum	nigram	nigrum, *etc.*

Prepositions. These are indeclinable. In Latin they are used with either the accusative or the ablative case.

The following take the accusative:

ante, before. *apud*, among, near.
ad, to, at. *adversus*, opposite to.

circum or *circa*, round, on both sides of
citra or *cis*, this side of.

erga, towards. *contra*, against.
inter, among, between. *extra*, outside of.

infra, below. *intra*, within.
juxta, close to. *ob*, on account of.

penes, in the power of. *pone*, behind (rare).
post, behind, after. *praeter*, beyond, except

prope, near to.
propter, on account of, thanks to.
per, through.

secundum, along. *supra*, above, beyond.
versus, in the direction of.

ultra, beyond. *trans*, across.

The following take the ablative:

a (*ab*, *abs*), by, with, from. *cum*, with. and *de*, down from; concerning

coram, in the presence of. *pro*, in front of, on behalf of. with *ex* or *e*, out of, from

tenus, as far as. *sine*, without. also *prae*, in front of

The four following take the accusative when they denote "motion towards," but the ablative when they denote "place at":

Sub and *Subter* (1) with accusative, "up to": *sub muros* up to the walls.
(2) with ablative, "beneath"

Super (1) with accusative, "above," "beyond", as, *super Indos* beyond the Indians.
(2) with ablative, "on"

In (1) with accusative, "into, to, against"
(2) with ablative, "in, at, on"

Prepositions usually come before their nouns, except *tenus* and *versus*, e.g. *Romam versus*, in the direction of Rome. *Tenus* can be used with the genitive. Also write *mecum*, *tecum* (with me, with thee), not *cum me*. (*See* Pronouns, next lesson.)

Verb "to be."

INDICATIVE MOOD.

	Singular	*Plural.*
PRESENT TENSE		
1st person	sum, *I am*	sumus, *we are*
2nd person	es, *thou art*	estis, *ye are*
3rd person	est, *he, she*, or *it is*	sunt, *they are*
FUTURE TENSE		
1st person	ero, *I shall be*, etc.	erimus
2nd person	eris	eritis
3rd person	erit	erunt
IMPERFECT TENSE—		
1st person	eram, *I was*, etc.	eramus
2nd person	eras	eratis
3rd person	erat	erant
PERFECT TENSE—		
1st person	fui, *I have been*, etc.	fuimus
2nd person	fuisti	fuistis
3rd person	fuit	fuerunt
FUTURE PERFECT—		
1st person	fuero, *I shall have been*, etc.	fuerimus
2nd person	fueris	fueritis
3rd person	fuerit	fuerint
PLUPERFECT—		
1st person	fueram, *I had been*, etc.	fueramus
2nd person	fueras	fueratis
3rd person	fuerat	fuerant

SUBJUNCTIVE MOOD.

	Singular.	*Plural.*
PRESENT—		
1st person	sim, *I may be, or let me be*	simus
2nd person	sis, *thou mayest be*	sitis
3rd person	sit, *he may be, or let him be*	sint
IMPERFECT		
1st person	essem, *I might be*	essemus
2nd person	esses	essetis
3rd person	esset	essent
PERFECT—		
1st person	fuerim, *I may have been*	fuerimus
2nd person	fueris	fueritis
3rd person	fuerit	fuerint
PLUPERFECT—		
1st person	fuissem, *I should or might have been*	fuissemus
2nd person	fuisses	fuissetis
3rd person	fuisset	fuissent

IMPERATIVE MOOD.

PRESENT		
	es, *be thou*	este, *be ye*
FUTURE		
	esto, *thou must be*	estote, *ye must be*
	esto, *he must be*	sunto

INFINITIVE MOOD.

PRESENT—esse, *to be*.

PERFECT AND PLUPERFECT—fuisse, *to have been*.

FUTURE PARTICIPLE—futurus, *about to be*.

FUTURE INFINITIVE—futurus esse, *to be about to be*.

NOTE.—To form the Imperfect Subjunctive of a verb, add *m* to Present Infinitive: *esse, essem*. Likewise add *m* to Perfect Infinitive to form Pluperfect Subjunctive—*fuisse, fuissem*.

SECTION II—SYNTAX

Rule 1. A finite verb agrees with its subject (or its nominative case) in number and person. [This does not apply to the infinitive mood.] For example, *Servus adest*, the slave is present. *Adsum*, I am present. *Magistri aderunt*, the masters will be present. [*Adsum* is a compound of the preposition *ad* and *sum*.]

Rule 2. An adjective (or pronoun or participle) agrees in number, gender, and case with the substantive to which it is attached—*e.g.*, *Cara est patria*, dear is one's native-land. *Habeo* (= I have) *multos equos*, I have many horses.

Rule 3. A substantive may have another substantive added to explain or describe it; the latter is then said to be in *apposition* to the former, and must agree with it in case—*e.g.*, *Filius Victoriæ, reginæ Britannorum, rex erit* = the son of Victoria, queen of the Britons, will be king. [*Reginæ* is genitive, in apposition to *Victoriæ*.]

NOTE: Any finite part of the verb *sum* is usually a copula or link, linking the complement to the subject—thus, *Edwardus est rex* = Edward is king. The complement will, of course, agree with the subject in *number* and *case*, and (if the complement be an adjective) in *gender* as well—*e.g.*, *Bellum erit longum* = the war will be long.

VOCABULARY TO LEARN BY HEART.

War—Bellum, *genitive* belli	**Wave**—Unda, -æ.
Romans—Romani, *genitive*, Romanorum	**Friend**—Amicus, -i.
Ally—Socius, -i.	**Pear-tree**—Pirus, -i.
Gauls—Galli, -orum	**Slave**—Servus, -i.
Long—Longus, -a, -um	**Town**—Oppidum, -i.
Path—Via, -æ	**Weak**—Invalidus, -a, -um
Wood—Silva, -æ	**Broad**—Latus, -a, -um.
If—Si (with *subjunctive*)	**Straight**—Rectus, -a, -um
Not—Non	**Britain**—Britannia.
And—Et	**Book**—Liber, libri
Miserable—Miser, misera, miserum	**Garden**—Hortus, -i.
Island—Insula	**Crown**—Corona, -æ.
	Gate—Porta, -æ
	Strong—Validus, -a, -um

The student is advised to write out the following sentences in Latin, and then compare them with the key given below, correcting his own version thereby and being careful not to refer to the key until he has made an independent effort to translate for himself.

1. The war between the Romans and the allies of the Gauls will be a long one (omit "one").
2. The path to (use preposition *ad*) the wood is broad and straight.
3. If she had been good ("she" need not be expressed; it will be conveyed by the gender of the adjective "good"), she would not have been miserable.
4. The island of Britain (say, "the island Britain," Britain being in apposition to island) is in the midst of (say "among") the waves.
5. The boy's book (the book of the boy) was the gift of (his) friend.
6. In the garden there had been a pear-tree.
7. I give (*do*) a crown to the good slave.
8. I walk (*ambulo*) to the gates of the town.
9. Let us be friends and allies to the weak slaves.
10. "To be" is good (neuter); "to have been" is better (*melius*, neuter of *melior* = better).

KEY TO THE ABOVE SENTENCES.

1. Bellum inter Romanos et socios Gallorum erit longum.
2. Via ad silvam est lata et recta.
3. Si bona fuisset, non misera fuisset.
4. Insula Britannia est inter undas.
5. Pueri liber erat amici donum.
6. In horto fuerat pirus.
7. Do coronam bono servo (indirect object).
8. Ambulo ad portas oppidi. [NOTE: The dative, *portis*, would be wrong here; "to the gates" is not indirect object. Wherever "to" expresses "motion to," use *in* or *ad* with accusative.]
9. Simus amici et socii invalidis servis.
10. Esse est bonum: melius (est) fuisse.

SECTION III. TRANSLATION.

The student should translate the following sentences into English, first mastering the words in this vocabulary:

VOCABULARY TO LEARN BY HEART.

Probus, -a, -um—Good, honest.
Beatus, -a, -um—Happy.
Ut In order that (takes the Subjunctive).
Fluvius, -i—River.
Poeta, -æ (masc.)—Poet.
Humerus, -i—Shoulder.
Verus, -a, -um—True.
Amicitia, -æ—Friendship.
Castrum, -i—Fort (in pl. *castra* = a camp).
Albus, -a, -um—White.
Ludus, -i—School (also = play, game).
Parvus, -a, -um—Small.
Discipulus, -i—Scholar, pupil.
Lætus, -a, -um—Joyful.
Dominus, -i—Master.
Pallium, -i—Cloak.

1. Este probi ut beati sitis.
2. Oppidum Londinium est prope latum fluvium.
3. Servus sit penes dominum.
4. Vergilius erat poeta apud Romanos.
5. Pallium fuerat in humeris reginæ.
6. Vera amicitia est donum deorum.
7. Castrum Romanorum erat trans fluvium.
8. Si albi fuissent, non nigri fuissent.
9. In ludo erant parvi discipuli.
10. Læti sunt animi bonorum.

KEY TO THE ABOVE SENTENCES.

1. Be honest in order that you may be happy.
2. The town of London (note omission of "of") is near a broad river.
3. Let the slave be in the power of his master.
4. Vergil was a poet among the Romans.
5. The cloak had been on the queen's shoulders.
6. True friendship is the gift of the gods.
7. The fort of the Romans was across the river.
8. If they had been white (men) they would not have been black.
9. In the school there were small scholars.
10. Joyful are the minds of the good (men).

(NOTE: "Man" and "men" are often not expressed in Latin—*e.g. boni* = the good.)

The beginner is recommended, after writing out the above exercises, to reverse the process and turn the sentences immediately above this note into Latin, and the sentences beginning *Bellum inter Romanos* into English.

To be continued.

ENGLISH

By Gerald K. Hibbert, M.A.

THE ALPHABET. The English Alphabet is the ordinary Roman alphabet, with the addition of the letter w. It consists of twenty-six letters, which are written both as small letters and as capitals.

CAPITALS. A, B, C, D, E, F, G, H, I, J, K, L, M, N, O, P, Q, R, S, T, U, V, W, X, Y, Z.

SMALL. a, b, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, u, v, w, x, y, z.

Capital letters are used at the beginning of proper names; also at the beginning of every new sentence, and of every line of poetry. The pronoun I and the interjection O are always capitals. Capitals are also used when speaking of the Divine Being, *e.g.* Thou, He, and in such expressions as His Majesty, etc.

The English alphabet is both redundant and defective: redundant because it contains three letters (c, q, x) indicating sounds which are also indicated by other letters (c = k or s, q = k, x = ks or gs): defective because there are only twenty-six letters (twenty-three really) to express at least thirty-eight sounds. For the fifteen sounds which have no special letters, we use certain combinations of letters, as *ng, ee, au, sh, ch*, etc. We want a new alphabet of at least thirty-eight letters, one for each sound.

Vowels. The letters a, e, i, o, u are called *Vowels* (Lat., *vocalis* = soundable), because they can be fully sounded by themselves, and with no check in the passage of the breath. The remaining letters are called *Consonants* ("sounding with"), because they cannot be fully articulated without a vowel sound along with them: they are voice checks.

W and *y* are semi-vowels; when they are followed by a vowel sound in the same syllable, they are consonants, as *world, yield*. When a vowel precedes them in the same syllable they combine with it to form either a diphthong (see below), or a simple vowel sound, as *few, buy*. *Y* is a pure vowel when followed by a consonant, as *Ygdrasil*: this was its original use, it was first used as a consonant after the Norman Conquest.

When two vowel sounds are pronounced as one syllable we have a *diphthong* ("double sound"). The four true diphthongs are:

1. *i*, as in *bind, find* (*cf.* the same sound in *aye*). This sound = *a* + *i*.
2. *oi* or *oy*, as in *hoist, boy, buoy*. It = the sound of *a* in *fall* + *e*.
3. *eu*, as in *euphony*: this diphthong is also found in *mute, cue, chew, beauty, suit*.
4. *ou* or *ow*, as in *how, pound*.

NOTE. In cases where two vowels are written, but only one pronounced (*gauge, boat, men*), we have not a proper diphthong.

The primary vowel sounds are *i* (as in *pit*), *ā* (as in *far*), and *ū* (as in *pull*): all the others are modifications of these.

The simple vowel sounds in English, as given by Mason, are thirteen, viz.:

1. The sounds of *a* in *tall, father, fate, fat*;
2. The sounds of *e* in *met* and *mete*;
3. The sound of *i* in *pin*;
4. The sounds of *o* in *not* and *note*;
5. The sounds of *u* in *rule, pull, fur*, and *but*.

Consonants. These are classified thus:

1. LIQUIDS: *l, m, n, r*. They run smoothly and easily into the sounds of certain other consonants: *e.g. mb, mp, nd, nt*, etc.
2. SIBILANTS (hissing letters): *s, x, z*, soft *ch, sh*, and *j* (or soft *g*).

3. MUTES = all the remaining consonants, except *h*. These are divided into three classes, according to the part of the mouth or throat chiefly used in their pronunciation:

   a. LABIALS (*labium* = lip): *b*, *p*, *f*, and *v*.

   b. DENTALS (*dens* = tooth): *d*, *t*, and *th* (*th* is sharp in *think*, flat in *this*).

   c. GUTTURALS (*guttur* = throat): *g*, *k*, hard *c* and *ch* (as in *loch*), and *gh*.

NOTE. *C is hard (= k) before a, o, u (cat, cot, cut); but soft (= s) before e, i, y (cedar, cider, cyst). In Old English c was always hard, and k was a superfluous letter. The soft sound of c is due to French influence after the Norman Conquest. Similarly with g: it is hard before a, o, u; and sometimes hard and sometimes soft before e and i (get, give, gem, giant). Ch and gh are now used as aspirates only in Lowland Scotch. Ch is usually soft in English (much, child; and = sh in machine); it is sometimes hard (ache). Gh in English is (1) silent, as though, (2) = f, as enough.*

H forms a class by itself. It resembles a consonant in that it cannot be articulated by itself, but it is not properly a consonant. It is a simple impulse of the breath, and is called an *aspirate* (*spiro* = I breathe). It was originally a guttural, and still retains this sound in Scotland and the north of England. In some words *h* is silent (heir, hour, honour); in certain others it is doubtful (*e.g.* some people say *hospital*, others *'ospital*). In words beginning with *wh* (who, why), the *h* should be sounded, *e.g.*, *what* is not pronounced as *wot*, but as *h wot*.

Q, as has been said, is a superfluous letter. It is always followed by *u*, and in Old English this sound was expressed by *cw* (*cwen* = queen).

Defects in English Spelling. A perfect system of spelling or writing would be *phonetic*, *i.e.* would indicate exactly the sounds made in speaking. For this purpose it is necessary:

1. That there should be a letter for each spoken sound;
2. That each letter should stand for only one sound;
3. That, in writing a word, no sound should be omitted and no unpronounced letters should be added.

English spelling breaks all these rules:

1. As there are only twenty-three letters for thirty-eight sounds, there are fifteen sounds without corresponding letters.
2. The letter *a*, for example, represents five simple vowel sounds, as in *fate*, *fall*, *far*, *fat*, *want*; so does *e* (*mete*, *pet*, *herd*, *clerk*, *pretty*); *i* represents two simple sounds (*pit*, *fir*) and one diphthongal (*bite*); *o* represents three sounds (*poke*, *pot*, *for*); *u* represents four (*rude*, *pull*, *fun*, *fur*). *Cf.* *his* and *this*; *dough* and *cough*.
3. Letters are often written which are not pronounced; these are useless as signals of the spoken word:

   E.g., *c* is useless in *duck*, *scene*.
   g „ „ *gnat*, *reign*.
   k „ „ *knee*, *know*.

Syllable. This consists of a single vowel or a collection of letters pronounced together, and has only one vowel sound. Words consisting of one, two, or three syllables are called respectively monosyllables, disyllables, and trisyllables; words of more than three syllables are called polysyllables (Gk., *polys*, "many").

In dividing a word into syllables we must as far as possible indicate the significant parts of which the word is composed, *e.g.* trans-act, not tran-sact; e-rect, not er-ect. There is, however, a limitation to this rule, for words must be divided in writing according to the way in which the elementary sounds are grouped in speaking, *i.e.* the division is usually made after the vowel, and the following consonant is carried on to the next syllable, *e.g.* hu-mour, fa-cing.

Accent is the stress of the voice upon a syllable as cataract, pervérsion, corróde. Difference of accent is often the only distinction between nouns and verbs, *e.g.* rébel and rebél, prógress and progréss. Many words have changed their accent, and the tendency of English is to throw the accent back towards the beginning of a word. Thus Shakespere uses *contráry*, Milton *blasphémous*, Pope *compénsated* and *efföct*, etc.

Parts of Speech. They are eight in number:

1. Noun	5. Adverb.
2. Adjective (and Article).	6. Preposition.
3. Pronoun.	7. Conjunction.
4. Verb.	8. Interjection.

Noun. A word used as the name of something (*nomen* = name).

CLASSIFICATION OF NOUNS. There are two main classes of nouns: 1. PROPER NOUNS; 2. COMMON NOUNS.

1. A *Proper Noun* is a name appropriated (Latin, *proprium*) to one particular thing or person, *e.g.* Joan of Arc, Abraham, John Jones, the Cæsars, Mont Blanc.

2. A *Common Noun* is a name which all things of the same kind have in common (*communis* = shared by several). All nouns not proper are common. Examples: cat, town, coal, water, book.

NOTE. Proper nouns may be converted into common, *e.g.* "he is the *Rupert* of debate." Similarly, a common noun may become proper, *e.g.* "I am going up to *Town*" (meaning "London").

Common nouns are subdivided into:

1. *Ordinary Class Names*, *i.e.* names belonging to each individual of a class, or to each portion of some sort of material, *e.g.* tree, iron.

2. *Collective Nouns*, denoting a number of persons or things forming one body, *e.g.* committee, jury, herd. In the plural such nouns stand for several similar collections: *e.g.* the Parliaments of Europe. As a rule, a collective noun has its verb in the singular: "the Government has abdicated"; but when attention is directed to the individuals composing the subject, the verb is plural: *e.g.* "the jury were right in finding the prisoner guilty."

3. *Abstract Nouns*, denoting not objects, but quality, action, or state, *e.g.* *drowsiness*, *walking*, *manhood*. Also names of arts and sciences, as *music*, *biology*.

INFLEXIONS OF NOUNS. Nouns are inflected to mark Gender, Number, and Case. This is called Declension.

Gender. Gender distinctions in English are beautifully simple. All names of animals of the male sex are masculine; names of animals of the female sex are feminine; names applied to animals of either sex are of common gender (*sheep, swan*); and names of things of neither sex are neuter. This is a *natural* distinction of gender based on a *natural* distinction of sex. (In other languages, gender becomes a merely grammatical distinction; thus, in Latin, *mensa*, = a table, is feminine because it ends in *-a*.) Of course, when lifeless things are personified, they cease to be of neuter gender, and are made masculine or feminine: *e.g.* the moon is spoken of as *she*; the sun as *he*; a ship as *she*.

There are three ways of indicating difference of gender in nouns.

1. *By Inflexion*, the gender being indicated by the termination of the word.

(a) Different suffixes used for masculine and feminine:

Masculine.	*Feminine.*
Sorcerer	Sorceress
Murderer	Murderess
Governor (ruler)	Governess (instructress)
Emperor	Empress

NOTE. The ending *-er* is a true English suffix; its feminine was *-ster*, of which *spinster* is the only example now in use. "Songster" and "Seamster" were originally feminine, so "songstress" and "seamstress" are double feminines. Therefore although certain words ending in *-ster* are now used as masculine, they once denoted occupations carried on by women, *e.g.* tapster (bar-maid), maltster, brewster, huckster, baxter (bake), webster (weave), etc.

(b) The feminine formed from the masculine by adding feminine suffixes:

(i) By far the commonest of these is *-ess*, *e.g* actor, actress; hunter, huntress; negro, negress; votary, votaress; peer, peeress; Jew, Jewess; abbott, abbess (shortened from "abbadess"); lad, lass (laddess); master, mistress (vowel modified); duke, duchess (French, *duchesse*); marquis, marchioness

(ii) *-en*, an old Teutonic feminine suffix, of which only one pure English example remains: *vixen*, from *fox* (German, Füchsin).

(iii) The following suffixes are foreign importations: *-trix* (executrix), *-ine* (heroine), *-ina* (czarina), *-a* (sultana)

NOTE. In the following words the masculine seems formed from the feminine:

Masculine.	*Feminine.*
Widower	Widow
Bridegroom (groom = man)	Bride
Gander	Goose (old form *gans*)

2. The second way of indicating difference in gender is by prefixing or affixing a word significant of sex to nouns of common gender:

Masculine.	*Feminine.*
Cock-bird	Hen bird
He goat	She goat
Man-servant	Maid servant
Buck rabbit	Doe rabbit
Pea-cock	Pea hen

3. The third way of indicating difference of gender is by using distinct words:

Masculine.	*Feminine*
Man (originally common)	Woman (wife man)
Father (one who feeds)	Mother (bringer forth)
Son	Daughter ("milkmaid")
Husband (house bonda, or manager)	Wife (a woman)
King (Cyning)	Queen (female, or mother)
Lord (loaf ward, hlaford)	Lady (hlaefdige)
Monk (monachus, a lonely dweller) / Friar (brother)	Nun (nonna = grand mother)
Drake (king of the ducks)	Duck (diver)
Uncle	Aunt
Wizard	Witch
Sir (senior)	Madam (mea domina = my lady)

To be continued

FRENCH

By Louis A. Barbé, B.A.

THE French alphabet, like the English, consists of twenty-six letters, including W, which occurs in a few words of foreign origin.

The names of these letters are:

A .. called	āh	O .. called	o
B .. „	bey	P .. „	pey
C .. „	cey	Q .. „	kü (see U below)
D .. „	dey	R .. called	érr
E .. „	ey	S .. „	ess
F .. „	eff	T .. „	tey
G .. „	jay without the initial *d*-sound	U .. „	ü (pronounced as the vowel sound in "rumour," but short)
H .. called	āhsh	V .. called	vey
I .. „	ee	W .. „	doobl vey
J .. „	jēe without initial *d*-sound	X .. „	icks
K .. called	kah	Y .. „	ee-greck
L .. „	ell	Z .. „	zed
M .. „	emm		
N .. „	enn		

The Vowels. The vowels are A, E, I, O, U, Y. Let us consider them in their order.

A.

In pronunciation the vowel *A* may have either a long or a short sound. The long sound resembles that of the English *a* in *father*. The short sound has no absolute equivalent in English. The nearest approach to it may be got by pronouncing such words as *bat*, *cat*, with the mouth well open. *A* is occasionally silent, as in *août*, (*August*), pronounced ōō.

E.

There are three kinds of *E*—mute *e*, closed *e*, and open *e*. When the final letter of a word of more than one syllable, *e* mute is really silent; but it causes the preceding consonants to

be sounded clearly. Thus the proper pronunciation of *porte* is got by making the *t* felt.

In the body of a word *e* mute is practically dropped in ordinary conversation. Thus *relâche*, pronounced *r'lahsh*.

In monosyllabic words, such as *je* (I), *me* (me), *le* (the), the *e*, though mute, is felt slightly. The sound has no exact English equivalent. It has some resemblance to the slurred sound of *e*, as colloquially pronounced in such a combination as *the boy*.

In attempting to indicate this shade of sound in the phonetic explanations throughout this Course it will be written *ĕ*. This is also the sound of *eu*, as in *feu*, pronounced *fĕ*, fire; *bleu*, pronounced *blĕ*, blue; *œu*, as in *bœuf*, pronounced *ĕf*, ox; *œuf*, pronounced *ĕf*, egg; *cœur*, pronounced *kĕr*, heart; *chœur*, pronounced *kĕr*, choir; *nœud*, pronounced *nĕ*, knot; *œuvre*, pronounced *ĕvr*, work; *sœur*, pronounced *sĕr*, sister; *vœu*, pronounced *vĕ*, wish; and of *œ*, as in *œil*, pronounced *ĕ-yĕ*, eye.

E has the sound of *a* in *femme*, pronounced *fam*, woman.

E remains mute when followed by *s*, and, in verbs, by *nt*. Thus, *porte*, *portes*, and *portent* are all pronounced *port'*. The sound of closed *e* is approximately that of *e* in *bet*, *met*. It is indicated by an acute accent thus, *é*. Open *e* has no exact counterpart in English. There is an approach to it in the *a* of *fame*. The sound has two modifications, the one rather shorter than the other. The one occurs in monosyllabic words ending in *es*, as *les*, the plural of the definite article *le*, and in *mes*, *ces*, *ses*, the plurals of the adjectives my, this, and his. It is also indicated by the grave accent, thus *è*, as in *père*, pronounced *pairr* (father). The circumflex accent, *ê*, commonly marks the other, as *tête*, pronounced *tate* (head).

I.

The sound of the vowel *I* resembles that of the English *ee* in *feel*, as *île* (island). There is a shorter, but not essentially different sound of the letter, as in *il* (he).

O.

The vowel *O* has a clearer and more definite sound than in English. When long, its length is about that of the English *o* in *rose* or *shore*. As far as mere length goes, *o* short is equivalent to *o* in *not*.

U.

There is nothing in English resembling the French sound of *U*. To produce it, keep the lips well rounded and pursed while attempting to pronounce English *e*. The actual sound of the vowel is not materially affected by its being short or long.

Y.

Y is equivalent to I at the beginning of a word, as *yeux*, pronounced *ee-e* (eyes), or after a consonant, as *style*, pronounced *steel*. When preceded by a vowel it is pronounced like *ii*; thus *pays* (country), *citoyen* (citizen), *abbaye* (abbey), become *pay-ee*, *seet-wo-yaww'**, *ab-ay-ee*.

* See explanation of ' symbol under M and N.

For the proper pronunciation of the French vowels, it is of great importance to remember that each of them represents one single definite sound, whether short or long, and not a combination of vowel sounds as is sometimes the case in English.

The names of the vowels when used as substantives are all of the masculine gender. Of the consonants, *f*, *h*, *l*, *m*, *n*, *r*, *s* are feminine, but all the others are masculine.

Vowel Sounds. The vowel sounds are represented, not only by single vowels, but also, in certain cases, by combinations of vowels. Thus:

1. The sound of A occurs in *Oi*, in which, however, it is preceded by, and closely connected with *ou*: *oi* = *oua*.

2. The sound of mute *e* is produced by *ai* in certain parts of the verb *faire* (to do), as *faisant*, *nous faisons*, *je faisais*.

The closed sound of *e* (*é*) is sometimes represented by *er* and by *ai*, as in *aimer*, *j'aimai*.

The open sound of *e* (*è*) is also produced by *ais* and by *ei*, as in *mais*, pronounced *may* (but), *peine*, pronounced *pen* (pain).

3. The long and short *o*-sounds have equivalents in *au*, *eau*, *aux*, *eaux*, as in *Paul*, *mauvais* (bad) *bateau* (boat) *aube* (dawn) *châteaux* (castle).

4. The sound of *U* is represented by *eu* in certain parts of the verb *avoir*, as in *j'eus eu*, pronounced *ji-zü*, I had had.

The Consonants. There are twenty consonants, which it is important that we should now consider.

B.

The consonant *B* is pronounced as in English, thus, *barbe* (beard). As a final, it is not sounded in *plomb*, pronounced *plon'**, lead.

C.

C has the hard sound of *k* before the vowels *a*, *o*, *u*, as *cap*, pronounced *kahp*, cape; *cou*, pronounced *koo*, neck; before consonants, as *classe*, pronounced *klas*, class; *cri*, pronounced *kree*, cry; and at the end of words, as *avec* (with), *bec* (beak), *parc* (park).

It has the soft sound of *s* before the vowels *e*, *i*, *y*, as *ceci*, pronounced *sesee*, this; *cité*, pronounced *seetey*, city; *cyprès*, pronounced *seeprè*, cypress.

In *second*, pronounced *ze-gon'*, and its derivatives, *c* is pronounced like *g*.

C after *s* at the beginning of a word or syllable is not sounded; thus, *science*, *scène*, are pronounced *see-awn's*, *sane*.

C final is silent in a few words, of which the most usual are *banc*, pronounced *bawn'*, bench; *flanc*, pronounced *flawn'*, side; *blanc*, pronounced *blawn'*, white; *clerc*, pronounced *clare*, clerk; *franc*, pronounced *frawn'*, franc; *tronc*, pronounced *tron'*, trunk; *porc*, pronounced *por*, pig.

Ch has the hard sound of *k* in most words derived from the Greek. It has the soft sound of *sh* in *archevêque*, pronounced *ahrsh-ay-vake*, archbishop; *archipel*, pronounced *ahrsh-ee-pel*, archipelago.

D.

D, as the first letter of a word or syllable, is sounded as in English, thus: *dôme* (dome). As a final it is usually silent, as in *bord*, pronounced *bor*, edge; but when linked in pronunciation to a word beginning with a vowel or a mute *h*, it assumes the sound of *t*; *grand ami* becomes *grawn'-tami*, great friend. This linking does not affect the sound of *d* in words in which it is pronounced as a final, as *sud* (south). Thus, we say *sud-est* (south-east) with a *d*-sound.

F.

Initial *F* has the same sound as in English. As a final it is usually sounded, as *vif* (lively), *bref* (brief), *serf* (serf). The exceptions to this are *clef*, pronounced *klēy*, key; *cerf*, pronounced *sair*, stag; and *cerf-volant*, pronounced *sair-volawn'*, kite; *chef-d'œuvre*, pronounced *shēy-devrr*, masterpiece, and the plurals *œufs* and *bœufs*, eggs and oxen. Authorities differ as to whether it is silent or sounded in the singular *nerf*. All agree as to its being silent in the plural *nerfs*. In the numeral *neuf* (nine), the *f* is silent before a word beginning with a consonant or *h* aspirate, if that word be multiplied by the numeral; but not otherwise. Thus, *neuf mois* (nine months) is pronounced *nĕ-mwa*, whilst in *le neuf janvier* (the ninth of January) the final *f* is heard. In the same numeral the final *f* assumes the sound of *v* before a multiplied word beginning with a vowel or *h* mute, as in *neuf heures*, which becomes *nev-ĕrr*.

G and J.

G has a hard sound, as in the English words *gave*, *grave*, *glimpse*, when it comes before *a*, *o*, *u*, *l*, and *r*, as in *galon*, pronounced *galon'*, gallon; *gosier*, pronounced *goz-ee-ey*, throat; *gloire*, pronounced *glwarr*, glory; *agréable*, pronounced *a grey abl*, agreeable.

In order to get the same guttural sound before *e* and *i*, the *g* must be followed by *u*, which, however, is not otherwise sounded, thus: *guérir*, pronounced *ghereer*, to cure; *guide*, pronounced *gheed*, guide. There are a few words in which the *u* of *gui* and *gue* is felt. These words are—*aiguille*,* pronounced *egg-wee-ĕ*, needle; *aiguillon*,* pronounced *egg-wee-on'*, goad; *aiguiser*, pronounced *egg-wee-zēy*, to sharpen; *arguer*, pronounced *ahr-guēy*, to argue; and the proper nouns Guise, pronounced *Gweez* and *Guizot*, pronounced *Gweezo*.

The nearest equivalent to the soft sound of *G* is represented by *si* and *su* in such English words as *vision*, *measure*. It naturally assumes this sound before *e* and *i*, as in *gentil*, pronounced *jawn'-tēē* (nice). When it is required to give it this soft sound before *a* or *o*, an intermediate *e* must be introduced, as in *geai*, pronounced *jey*, jay.

The sound of *J* is identical with this soft sound of *g*, as in *joli* (pretty), *jeune* (young).

The *d*-sound which in English constitutes a part of the pronunciation of *j*, and sometimes of *g*, as in *Jane*, *George*, must be carefully avoided in French.

Final *g* is silent in *faubourg*, pronounced *fo-boor*, suburb; *doigt*, pronounced *dwa*, finger; *vingt*, pronounced *van'*, twenty; *étang*, pronounced *etawn'*, pond; *hareng*, pronounced *arawn'*, herring; *long*, pronounced *lon'*, long; *sang*, pronounced *sawn'*, blood; *rang*, pronounced *rawn'*, row.

When final *g* is carried on to a word beginning with a vowel, it takes the sound of *k*, thus; *sang et eau* is pronounced *sawn'key-ō*, blood and water.

H.

Initial *H* is not sounded; but in words in which it is said to be aspirated, it prevents the elision or dropping of the final vowel, and the carrying on or linking of the final consonant in certain words that precede them. Thus, *h* being aspirated in *héros* (hero) and *hache* (hatchet), we say *le héros*, *la hache*, *les héros*, *les haches*. Mute *h* is non-existent for purposes of pronunciation, so that the words in which it occurs practically begin with a vowel, and consequently allow both elision and linking. Thus, with *homme*, pronounced *om* (man) and *histoire*, pronounced *ees-twahr* (history), we get *l'homme*, *l'histoire*, and we pronounce *les hommes*, *les histoires* as *lé z (h)ŏm*, *le z (h)ees twahr*. H, though aspirated in *héros*, is silent in all its derivatives: *l'héroïne*, *l'héroïsme*, etc.

K.

The letter *K* is found only in a few words of foreign—mainly Greek—origin. Its pronunciation offers no difficulty.

L.

The simple and natural pronunciation of *L* is the same as in English: *laurier*, pronounced *lor-ee-ey*, laurel; *chaloupe*, pronounced *shaloop*, shallop.

Final *l* is not sounded in *baril* (barrel), *chenil* (kennel), *coutil* (duck), *cul de sac* (blind road), *fusil* (gun), *gril* (gridiron), *nombril* (navel), *outil* (tool), *persil* (parsley), *soûl* (surfeited), *sourcil* (eyebrow), nor in *gentil*, except when it is followed by a word beginning with a vowel or an unaspirated *h*.

In certain words final *l* preceded by *i* assumes a liquid sound. With regard to the proper pronunciation of this liquid sound there is a difference of usage and of opinion. The simplest form of it consists in giving the *l* the value of very short *ye*, without, however, allowing it to form a separate syllable. The words that have this liquid sound of final *l* are: *avril*, pronounced *av ryee*, April (according to some authorities), *babil*, pronounced *babee-ye*, chatter; *cil*, pronounced *sea ye*, eyelash; *péril*, pronounced *perree ye*, peril.

The liquid sound of *l* occurs not only in certain words that have final *il*, but also the following terminations—*ille*, pronounced *ee ye* (except *ville*, town, and *mille*, thousand); *ail*, pronounced *aye*; *aille*, pronounced *aye*; *eil*, pronounced *aye*; *eille*, pronounced *āye*; *euil*, pronounced *ĕ ye*; *euille*, pronounced *ĕ-ye*; *œil*, pronounced *ĕ ye*; *ouille*, pronounced *ou-ye*; *uille*, pronounced *ou-ye*.

M and N.

Initial *M* is pronounced as in English, thus:

* See Liquid Sounds under L paragraph.

muse, pronounced *müze*, muse; *midi*, pronounced *mē dē*, midday.

Except in a few words, either Latin or of foreign origin, such as *item*, pronounced *ēetem*, item; *harem*, pronounced *arr-em*, harem, final *m*, together with the vowel preceding it, has a nasal sound.

This nasal sound arising from the letter *m* or *n* (not *mm* or *nn*), preceded by a vowel, should be pronounced without any *g*-sound. But as the nearest English equivalent always occurs with a final *g*, the phonetic explanation of the pronunciation of such words will in this course be accompanied by the *g* shown thus, ᵍ. For example: *champ*, pronounced *shawnᵍ*, field; *dans*, pronounced *dawnᵍ*, in, or into; *bon*, pronounced *bonᵍ*, good; *maison*, pronounced *may-zonᵍ*, house.

Nasal Sounds. 1. The nasal sounds are four in number: *an*, *in*, *on*, and *un*; but each of them represents various combinations. Thus:

2. The nasal sound of *an* is also that of *ant*, *and*, *anc*, *ang*, *am*, *amp*, *en*, *ent*, *em*, *emps*, and *aon*, and of *aen* in *Caen*.

3. The nasal sound of *in* is also that of *aim*, *ain*, *aint*, *eim*, *ein*, *eint*, *im*, *yn*, and *ym*.

4. The nasal sound of *on* is also that of *ont*, *ond*, and *om*.

5. The nasal sound of *un* is also that of *eun*, *unt*, and *um*.

6. All these combinations are, except in a very few words, pronounced with a nasal sound, when they are finals. As initials, or in the body of a word, they are nasal only when followed by a consonant other than *m* or *n*. Thus, *im* is nasal in *impossible* (*anᵍ poss-ēebl*).

7. *En* is nasal in *ennui* (*awnᵍ nwee*), and its derivatives.

M is silent in *automne*, pronounced *ō tŏn*, autumn, and also in *damner*, pronounced *dah ney*, to damn, together with the words derived from it.

Initial *n* is pronounced as in English, thus: *neuf*, pronounced *nŭf*, new; *ni*, pronounced *nēe*, nor. When followed by a vowel, it retains this sound in the body of a word, as in *anodin*, pronounced *an-o-danᵍ*, anodyne. *N* communicates the sound of *a* to the vowel *e* in *hennir*, pronounced *ay neer* (to neigh).

Except in *abdomen*, *amen*, *Eden*, and (according to some) *hymen*, pronounced *eemenn*, Hymen, final *n* gives the nasal sound to the syllable.

P.

Initial *P* is sounded very much as in English, but with a slighter opening of the lips, thus: *pas*, pronounced *pah*, step; *prune*, pronounced *prün*, plum; *poche*, pronounced *posh*, pocket. *Ph* has the value of *f*, as in English, thus: *phare*, pronounced *fahr*, lighthouse. It is sounded before *n* and *s* in words derived from the Greek, as: *pneumonie*, pronounced *pnŭ-mō-nēe*, pneumonia. It is usually silent before *t*, except in the initial syllable of words derived from the Greek, or from the Latin *septem*, thus: *septembre*. It is silent, however, in *baptême*, pronounced *bahteme*, baptism; in *compter*, pronounced *conᵍtey*, to count; *dompter*, pronounced *donᵍtey*, to tame; *sculpter*, pronounced *skültey*, to carve; and their derivatives; and in *exempt*, pronounced *exawnᵍ*, exempt; and *prompt*, pronounced *pronᵍ*, prompt. It is also sounded before *t* in *abrupt*, *inepte*, *adoption*, *captieux*, *reptile*, *accepté*, *rédempteur* (redeemer), and their derivatives. The meanings of the words are obvious.

Final *p* is usually silent, as in *camp* (camp), *champ* (field), *coup* (stroke), *drap* (cloth), *loup* (wolf), *galop* (gallop), *cep* (vine-stock), and also in *corps* (body) and *temps*, pronounced *tawnᵍ*, time. It is sounded in *cap* (cape). In *beaucoup*, pronounced *bō-kŏŏ*, much, and in *trop*, pronounced *tro*, it is sounded only before a word beginning with a vowel or mute *h*.

Q.

Except in *cinq*, pronounced *sanᵍk*, five, and *coq*, pronounced *kauk*, cock, the only two words in which it occurs as final, the letter *Q* is always followed by *u*. The combination *qu* has two different pronunciations, with regard to which no precise rules can be laid down. It may be said, in general terms, that *qu* is equal to *k* in words that belong to popular speech, as in *quoi*, pronounced *kwah*, what; *quitter*, pronounced *kee-tey*, to quit. In words commonly called of learned origin, *qu* has usually the sound of *kw* when it is followed by *a*, as in *aquatique*, pronounced *akwatēek*, and *equateur*.

In *cinq* the final *q* is sounded, except when that numeral multiplies a word beginning with a consonant or aspirated *h*, as *cinq francs*, pronounced *sanᵍ frawnᵍ*, five francs. In that case it is silent.

R.

The letter *R* is pronounced with a strong trill, produced by the vibration of the uvula, as in *rivage* (shore), *marine* (navy), *mercredi* (Wednesday).

Final *r* is sounded in the monosyllables *fer*, pronounced *ferr*, iron; *mer*, pronounced *merr*, sea; *cher*, pronounced *sherr*, dear; *or*, pronounced *or*, gold; *mur*, pronounced *mür*, wall; *fier*, pronounced *fēe-err*, proud; *hier*, pronounced *ēe-er*, yesterday; *sieur*, pronounced *sēe-er*, sir; but not in the compound *monsieur*. It is also sounded in final *ir*, as *plaisir*, in the dissyllables *amer*, pronounced *ahmerr*, bitter; *hiver*, pronounced *ēe verr*, winter; *enfer*, pronounced *awnᵍ-ferr*, hell; *éther*, pronounced *aterr*, ether; *cuiller*, pronounced *kwēe-yerr*, spoon; in a few Latin nouns and in some proper names.

Final *r* is silent in the combination *ier* in all polysyllables except those mentioned above, and in all infinitives in *er*.

S.

The letter *S* has two sounds—a sharp, hissing sound, as in the English word *sing*, and a softer *z*-sound, as in *fuse*.

Initial *s*, whether followed by a vowel or by a consonant, has the sharp sound, as in *sage*, pronounced *sahj*, wise; *scie*, pronounced *sēe*, saw.

In the body of a word *s* has the same sharp sound if it is either preceded or followed by another consonant, as in *lorsque*, pronounced *lawrsk*, when.

There is an exception to this in the case of words in which the Latin preposition *trans* occurs. Thus, *s* has the sound of *z* in *transiger* (to compromise), and in *transaction*.

The hissing sound is also produced by *ss* between two vowels, as in *passer*, pronounced *pah-sey*, to pass.

A single *s* between two vowels has the soft *z*-sound, as in *rose*, pronounced *rose*, rose; *misère*, pronounced *mëë-zairr*, misery; *maison*, pronounced *may-zon'*, house; *poison*, pronounced *pwah-zon'*, poison.

Final *s* is usually silent, as in *dans*, pronounced *dawn'*, in; *sous*, pronounced *soo*, under; *poids*, pronounced *pwa*, weight.

Final *s* is sounded in *tous* (pronoun), but not in *tous* (adjective), meaning "all."

When *plus*, pronounced *plü*, more, helps to form comparatives and superlatives, the final *s* is silent. It is also silent in *ne . . plus* no longer. It is sounded in *plus* = more, in *pas plus*, in *de plus en plus*, and in *plus-que-parfait*.

Final *s* is silent in *Jésus*.

T.

The sound of *T* is similar to that of the same letter in English, but rather softer, owing to the absence of the slight aspiration that generally follows it in English. Initial *t* always has the same value, as in *table* (*tahbl*), table. In the body of a word it retains this sound when it is followed by a consonant or any vowel but *i*, as in *entrain*, pronounced *awn'-train'*, dash; *entamer*, pronounced *awn'-tammey*, to broach.

In *ti*, the *t* retains its own pronunciation (1) when preceded by *s* or *x*, as in *bastion*, pronounced *ba-steeon'*, bastion; *mixtion*, pronounced *meex-teeon'*, mixture; (2) when followed by *tié* or *tier*, as substantive endings, thus: *amitié*, pronounced *amee-tee-ey*, friendship; *entier*, pronounced *awn'-tee-ey*, entire; (3) when followed by *e* mute, as in *partie*, *modestie*. The exceptions to this are a few nouns, of which *prophétie*, pronounced *profey-sëe*, is an example, and all nouns in *atie*, as *democratie* (democracy), in which *ti* becomes *ci* in pronunciation; (4) when followed by *en* or *enne*, as in *tenir*, to hold.

Final *t* is usually silent, but is sounded in *abject*, pronounced *abject*, abject; *brut*, pronounced *brütt*, coarse.

T final is silent in *vingt* (except when followed by a noun beginning with a vowel or mute *h*), in *quatre-vingts* (80) and all the numbers from 80 to 99. It is sounded in *vingt et un* (21) and all the remaining numbers up to 29.

It is also silent in *sept*, pronounced *set*, seven; and *huit*, pronounced *wëët*, eight, when these numerals multiply a number beginning with a consonant or aspirated *h*.

Final *t* is pronounced in *Christ*, and Protestants usually retain this pronunciation in *Jésus-Christ*. Catholics seem to prefer a pronunciation in which both *s* and *t* are silent, and say *Jésu-Chri*.

Th, whether initial, medial, or final, is pronounced like *t*, as in *thé* (tea), *méthode* (method), *zénith* (zenith). It is wholly silent in *isthme* (isthmus).

V.

The letter *V* is pronounced as in English, thus: *vivre*, pronounced *vëëvrr* (to live). It is never final.

W.

W never occurs except in words of foreign origin. It usually has the sound of *V*, but is sometimes pronounced like *oo* in English words, such as *whig* and *whist*.

X.

Initial *X* occurs in a small number of purely scientific terms derived from the Greek, and also in a few proper nouns of foreign—chiefly Greek—origin.

In the body of a word, *x* has approximately the same value as in English.

X has the value of *z* in *deuxième* (second), *dixième* (tenth), *sixième* (sixth).

In *soixante* (sixty), with its derivatives, and in *Bruxelles*, *x* has the sharp sound of *ss*.

Final *x* is usually silent, thus: *paix*, pronounced *pey* (peace), *prix*, pronounced *pree* (price).

It has the value of *ss* in *six* (six) and *dix* (ten), except when those numerals multiply a noun beginning with a consonant or an aspirated *h*, as *six heros*, *dix mois*. In that case it is silent.

When carried on to the next word, final *x* takes a *z* sound, thus: *deux hommes*, *six ans*, become *de-zom*, *see-zan'*.

Z.

Z is sounded as in English: *zone*, *gazon* (turf), *douze* (twelve).

Final *z* is silent in *nez* and *chez*. It takes the sharp sound of *s* in *Metz*.

A liquid sound peculiar to the French language is formed by the combination of *gn* in the body of a word. It approximates the *ny* of *Bunyan* or the *ni* of *union*. Thus, as regards this sound, there is a similarity between *compagnon* and *mignon* and their English equivalents *companion* and *minion*. When *gn* occurs in final *gne*, as in *signe* (sign), its sound may be approximated by giving it the value of a very slight and slurred *nye*: *seen-ye*.

ELECTRICITY

A SYSTEMATIC COURSE OF ELECTRICITY AND ELECTRICAL ENGINEERING

EMBRACING

THE DEVELOPMENT OF ELECTRICITY AND THE TECHNICAL PROCESSES ASSOCIATED WITH IT

INCLUDING

The Dynamo	Electricity Meters	Systems of Supply	Telegraphs
Electric Measurement	Electric Heating	Electric Lighting	Telephones
The Transformer	Electric Furnaces	Arc and Glow Lamps	Electroplating
Transmission of Power	Electric Motors	The Alternator	Electrotyping
Equipment of Factories	Electric Railways	The Condenser	Electric Cables

AND COMPRISING

THE APPLICATIONS OF ELECTRICITY IN MODERN SCIENCE, INDUSTRY AND COMMERCE

CONDUCTED BY

Professor SILVANUS P. THOMPSON, Doctor of Science; Fellow of the Royal Society; Past President of the Institution of Electrical Engineers; Principal of the City and Guilds Technical College, Finsbury; and

D. H. KENNEDY, of the Post Office Telegraphs and Telephones Department; Associate Member of the Institute of Electrical Engineers.

THE PLACE OF ELECTRICITY IN THE MODERN WORLD

By Professor Silvanus P. Thompson

AFTER the Stone Age, the Bronze Age, and the Iron Age, by which names learned men distinguish the steps of civilisation in pre historic time, come in rapid succession the Age of Steam and the Age of Electricity.

Let anyone try to picture to himself the quiet, slow-moving world in which our grandfathers and great-grandfathers lived, before the advent of the locomotive or the steamboat, before the telegraph or the telephone, before the electric light or the electric motor. To travel by coach from London to York required four days. To send a letter from London to Paris required at least a week. To sail from London to New York needed a month. Gas lighting made its appearance in the streets of our cities early in the nineteenth century; but, for the rest, the tallow candle and the dim colza oil lamp were the means of domestic lighting. The factories, thanks mainly to James Watt, had their steam-engines, of primitive type.

The Coming of the Steam Engine. With the advent of the steam-engine grew up our factory system, where men and women were herded together in dark factories, because steam power on any small scale for the individual worker was quite uneconomical. With the steam-engine as a pumping agent mining could progress, and town-supplies of water became a possibility. Not until the development of the locomotive in the middle of the nineteenth century were towns brought into reasonable communication with one another; nor until the marine engine had been developed could interchange of news and of products and manufactures between one country and another come into active existence. With the introduction of steam-engines began the taste, the fashion, and the general use of travel, the growth of markets dependent upon the rapid transportation of goods, and the establishment of national and international postage. All this vast development, the beginning of which our grandfathers witnessed, has gone on until our time, and still goes on. But its progress has been vastly hastened, and its extension widened by that still more modern and more scientific agency—electricity.

A Revolution of Our Own Time. Quite recent is the introduction of electricity into the service of man. While the electric telegraph in Great Britain dates from about 1840, the submarine cable from 1854, and the electric bell from about 1855, the commercial introduction of the telephone from about 1878, that of the electric light dates from about 1878, the public supply of electricity from about 1883, the industrial use of electric motors from about 1886, electric tramcars from 1883, electric railways from 1892, and wireless telegraphy, though its inception was in 1894, began to be used only in 1899.

The vast development of electric work to-day, with its thousand applications, has been the product of many minds, the fruit of the labours of comparatively few pioneers. The salient discoveries can be stated very briefly. Until the end of the eighteenth century, the only electrical facts which had been discovered or explored were those relating to the production by friction of electric charges, which could indeed be made to give shocks or sparks, but which had no commercial applications.

It was true that Benjamin Franklin had identified lightning as an electric discharge, and had invented the lightning-rod for the protection of property from thunderstorms. But so long as the artificial production of electric effects depended upon the rubbing of amber with flannel, or of glass with silk, this primitive excitation of stationary electric charges was barren of useful applications. It was not even

established that electricity had any connection with magnetism, though it was suspected that there were relations between the two agencies.

The Electric Current. With 1800 came the invention by Alessandro Volta of the voltaic pile, followed by its improved form, the voltaic *cell*. For the first time science was provided with a steady and manageable source, from which a quiet, continuous flow of electricity as a *current* could be procured. These currents could be guided along metallic wires, usually of copper, constituting an electric circuit, which conveyed the current from its starting-point in the cell—or, in more powerful combinations, from a whole battery of cells—to any required place, and led it back by a return path to the starting-point.

The properties of the electric current were quickly investigated. Metals and many liquids were found to conduct it: glass, marble, wax, oil, and air were found to stop its passage, acting as non-conductors or insulators. It was found to heat thin wires. In 1802 Humphrey Davy discovered the *arc* or electric flame produced when the current passes between the tips of two sticks of carbon. He also investigated the power of the electric current to cause chemical decomposition in passing through salt-solutions, through fused alkalis, or through acids. In 1820 Oersted discovered that the electric current could cause a deflection of a compass needle placed near the wire that carried the current, and so opened the new domain of electro-magnetism.

First Electric Motor. This was followed by the invention of the galvanometer, the instrument by which currents are detected and measured. In 1822 Faraday produced the first electric *motor*, in which a magnet was caused to rotate around a current, or the wire carrying the current was caused to rotate around a magnet. In 1825 William Sturgeon invented the soft-iron *electro-magnet*, an instrument of vast importance in all the modern engineering applications. Down to that time the only known magnets were either natural lode-stones or else pieces of steel (bars, needles, or horseshoes in form), to which magnetism was imparted once for all. Their magnetism was in this sense permanent, not capable of being turned off or on at will, not capable of being controlled from a distance. Sturgeon found that by winding a coil of wire around a rod or horseshoe of soft iron, and then connecting the coil by wires to an electric circuit which conveyed electric currents from a battery, so that the electric current circulated around the iron, the iron core became a powerful magnet, but continued so only so long as the electric current was permitted to circulate. On stopping the current, which could be done by opening the circuit at any point—which might be far away—the soft iron core ceased to attract. On re-closing the circuit the circulation of current began again, and the iron core again became magnetic, and exerted its pull on a neighbouring iron armature.

Here, then, for the first time in history, was man provided with a magnet that could be controlled and operated from any distance. The electromagnet is the beginning of all electrical engineering. An electromagnet is an essential feature in every modern telegraphic instrument, in every sounder, recorder, and relay, in every telephone, in every electric bell, in every motor, in every dynamo, in every electrically-operated railway signal. Millions of electromagnets are constructed every year; but the essential principle of them all goes back to William Sturgeon's electromagnet of 1825.

Generation and Transformation. In 1831 Michael Faraday made two discoveries of equally fundamental importance, when he established the principles of the *mechanical generation* of electric currents and of their *transformation*. Down to that date the only methods known for generating electric currents had been either the chemical method used in the voltaic cell, or the less useful method of the thermopile (discovered in 1822 by August Seebeck), in which heat applied to the junctions of metallic bars set up feeble electric action. But Faraday took a step far in advance when, after many failures and a deliberate and determined scientific search, he discovered a mechanical process for generating currents by the moving of magnets near coils of copper wire. Of this discovery, and of its far-reaching consequence—the invention of the dynamo—there is much to be said when we come to consider the dynamo. Suffice it here to say that without this transcendent discovery of the mechanical method there would have been none of the larger practical applications of electricity to engineering work.

Even as it was, no practical application of this method was adopted in commerce for a number of years. It is true that primitive kinds of dynamos, under the name of magneto-electric machines, were made for laboratory purposes. Faraday himself made such in 1831, Pixii in Paris and Saxton in London quickly followed with other forms. In 1841 Woolrich, of Birmingham, devised a machine capable of being driven by a steam engine, and furnished currents for electroplating; and Sinsteden, in 1851, devised the method of using a small magneto-electric machine to excite the magnets of a larger one, thus obtaining mechanically currents far exceeding those of the largest batteries previously known. He described experiments on the fusing of copper and iron wires, and made experiments on glow-lamps of platinum wire.

Era of Electric Lighting. From 1857 to 1865 inventors were busy perfecting magneto-electric machines for lighthouse lighting; while Wheatstone, Siemens, Varley, Pacinotti, and Wilde introduced various improvements in respect of greater continuity of current and in modes of exciting the magnetism of the magnets. In the early seventies a special pattern of dynamo by Gramme, of Paris, having as the revolving armature a continuous *ring-coil*, came into commercial use and quickly won its way. The era of electric lighting by arc lamps followed in the years from 1874 to 1884, succeeded by the introduction of the glow-lamp.

Amongst Faraday's inventions of 1831 was that of the induction coil or transformer, a

device by which an electric current flowing in a coil of wire induces a current to flow in a neighbouring coil of wire, the action being dependent upon the variations of strength of the primary current [see a later Chapter in this section on TRANSFORMERS].

The first application of this discovery was the spark-coil, an apparatus for obtaining bright long sparks by induction from a mere current from a few voltaic cells. The later application in the modern alternate current transformer for changing high pressure currents into low-pressure currents, or *vice versa*, came into commercial importance only about 1883, when alternate current generators had been put upon the market for the purpose of electric lighting. Without the transformer there would have been none of the great schemes for the electric transmission of power, or the utilisation of the energy of waterfalls, for such transmission of electric energy would be wholly uneconomical unless the current could be conveyed at very high pressures, and high pressure currents cannot be used for lighting or tramway work unless they are transformed down to a suitable low pressure. All this we shall see in due course [see Chapter on TRANSMISSIONS OF POWER].

Systems of Transmission. After alternating electric currents had thus been introduced, there came the invention by Ferraris in 1885, and by Tesla in 1888, of the combination of two, three, or more separate alternating currents in different *phases*, to work alternate current motors, and so arose the two-phase and three-phase systems of transmission—the latter predominating to-day in all the great schemes of electric engineering.

With batteries for the generation chemically of weak currents, the telegraph, the telephone, and the electric bell received their natural development. With dynamos for the mechanical generation—by steam engines, or water power, or gas engines—of continuous currents, there followed the application to electrotyping, electroplating, electro-gilding, and nickel-plating, as well as the supply of electricity to arc lamps for public lighting and glow-lamps for interior illumination, and to the propulsion of tramcars and electric locomotives. With the alternator for the mechanical generation—by power—of alternating currents, aided by the use of the transformer, came the utilisation of waterfalls and the transmission of electric power on the large scale from generating centres or power houses, the currents being transmitted to suitable distributing centres and there transformed down or converted into continuous current as required by the various consumers. The driving of factories by electric motors; the use of electric furnaces for smelting and the manufacture of alloys and of new chemicals; the propulsion of heavy trains by electric motors—all these became possible only by the developments just recited, and these all originate with the scientific researches of Michael Faraday.

A Recent Revolution. How great has been all this recent development a few statistics will reveal. Before 1880 there was not in Great Britain a single house electrically lighted, nor a single supply-station erected for the public distribution of electricity. At the end of 1895 there were 38 public companies for electric supply, with a total capital of £5,831,000, and 33 municipal undertakings with an authorised capital of £1,900,000. There were at that date about 2,000,000 of glow-lamps in use in Great Britain, and about 18,000,000 *units* of electric energy were supplied in that year to the public, the average working cost per unit being over fourpence. By New Year's Day in 1905 there were 183 public companies, with a total capital of over £30,000,000; 262 municipal undertakings, with authorised capital of £31,600,000. Nearly 20,000,000 glow-lamps were connected up, and over 448,000,000 of units of electric energy per annum were being sold with an average working cost reduced to 2·3 pence. In electric tramways, of which the first two were opened in 1883, there were in 1896 only sixteen companies, with a capital of £6,000,000. In January, 1905, these had grown to 159 companies, with a capital of £79,000,000, while 115 municipal bodies had spent £27,870,000 on tramways. The earliest of electric tube railways was the City and South London, opened in 1890, which has now 12½ miles of track. There are now in London alone 193 miles of track in electric operation, and 64 miles more are either under construction or in process of conversion from steam propulsion. In the provinces there are 146 miles of electric railway in operation, and over 100 more authorised or in process of conversion.

A Hundred Thousand Horse-Power. The number of electric bells sold in Great Britain alone averages something like a million a year. The total mileage of telegraph wires which, when taken over in 1870 by the State, was much under 100,000, is now over 300,000 miles. The number of telegraphic messages sent during the year 1904 was nearly 90,000,000, while the capital value of the telegraphs of Great Britain is estimated to be £36,000,000, and that of the telephones £13,200,000. Great power-houses for the generation and supply of electric energy to be transmitted to factories and workshops have been erected in a number of industrial centres, at Newcastle, in South Wales, in the Midlands, in the Clyde Valley, in North London, in Yorkshire, and in Lancashire, with others in progress. These together represent an output of over 100,000 horse-power, and a capital expenditure in total of £900,000. The invention by Parsons of the steam-turbine has given a great impetus to these latest developments.

It will thus be seen to what an immense commercial importance the electrical industry has grown. Without reckoning in any submarine cables or any manufacturing concerns, the total capital expended upon the electrical undertakings enumerated above may be approximately stated at over £220,000,000. If we put down the capital of the submarine cable companies at £25,000,000, and that of the electrical manufacturing undertakings in Great

each of these containing at least two sorts of atom. A substance is known as *complex* when its molecules are composed of a large number of atoms. Protoplasm is undoubtedly complex in this sense, though it must not be supposed that it is necessarily a substance of definite chemical composition, as are water, starch, and cane-sugar. Very complex substances are eminently unstable, and when protoplasm dies it no doubt "falls to pieces," so to speak.

The Chemistry of Life. As we can only subject dead protoplasm to chemical analysis, a great difficulty presents itself when attempts are made to determine its actual chemical nature. But we know that its nearest allies are to be found in what are termed *proteids* or *albuminoids*, of which white-of-egg is a typical example. Yet even these are so complicated in nature that so far we know little more than their percentage composition, and till they are thoroughly understood the true nature of living matter is far to seek. Chemistry, however, has made such huge strides in the past that we are justified in expecting further enlightenment in the immediate future.

At no very distant date a sharp distinction was drawn between Inorganic and Organic Chemistry, the latter dealing with substances which it was supposed could only be formed by the vital activity of plants or animals. But as since then some of these very substances, *e.g.* grape-sugar and indigo, have been actually built up or synthesized in the laboratory, the same may ultimately prove possible for proteids. Some sanguine spirits even anticipate that living substance will some day be manufactured. Should this dream of the old alchemists ever be realized, we shall be justified in considering life a matter of chemistry and physics; but till then it is better to remain in an attitude of suspended judgment.

A Cycle of Changes. Living matter is further distinguished from non-living by the fact that it passes through a *cycle of changes*, which terminate in death with resolution into non-living substances. It is, indeed, possible that death is not an absolute necessity in the case of certain of the lowest animals, as we shall see in the sequel. But the statement is broadly, if not universally, true. During the life of an organism there is a constant breaking down of the complex substance of the body, associated with an equally constant up-building, whereby waste is compensated, growth rendered possible, and the production of new individuals made practicable. Without such chemical breaking-down the energy necessary for carrying on the various acts of life would not be available. In ourselves, for example, movement, the production of digestive juices, sensations, and even thought, are all associated with such disintegration. There is a constant ebb and flow. The body of an organism retains a constant form with changing substance, like an eddy in a stream. It may be added too that the form is typically bounded by curves.

Turning to non-living matter, we find that these cyclical changes are not manifested. A piece of rock-crystal, for instance, may retain its properties unchanged for an indefinite period. Under certain circumstances, indeed, it may grow, as do crystals of sugar-candy on a string, but the growth takes place by the addition of layers to the exterior, the interior remaining unaltered. And when non-living matter has a definite shape, as in crystals, it is bounded by sharp edges, and, as a rule, by flat surfaces. Some crystals, as those of diamond, may, it is true, possess curved faces, but the sharp edges are always there.

The Kingdom of Biology. The distinctions between higher plants and higher animals are sufficiently obvious, though both are essentially composed of protoplasm; but as we descend the scale the differences become less striking, until among the lowest forms of life it is not always possible to be absolutely sure in a given case whether we are dealing with a plant or an animal. We may, in fact, compare the two great kingdoms of the organic world to the two strokes in a V, which are distinct above, but unite together below, while the letter Y may be taken to represent both kingdoms, together with the common stock from which they have probably been derived. The actual points of difference are best reserved till we know a little more about plants and animals.

So much is known about the myriads of organisms which either exist or have existed, that plants and animals are commonly dealt with separately by the two sister sciences of Botany (Greek, *botanē*, a plant), and Zoology (Greek, *zōon*, an animal; *logos*, a discourse), which treat respectively of plants and animals, though it must not be forgotten that these are not marked off from one another with absolute distinctness, besides which they are inter-related in so complex a fashion that many problems can only be adequately solved by the co-operation of botanists and zoologists.

Either Botany or Zoology is susceptible of division into departments, though here, again, there is necessarily more or less overlapping. The first of these departments is Classification.

Classification. When dealing with a multitude of objects of any kind, it is an obvious matter of convenience to divide them into groups, according to their resemblances and differences, in other words to *classify* them. Postage stamps, coins, books, pictures, or what not, all require classification if they are to be studied intelligently, and the proprietor of every shop is aware of the necessity of arranging his wares according to some definite plan, so that customers can be served with promptitude and ease.

In similar wise naturalists have long been accustomed to adopt some kind of classification of plants and animals, and one of the most notable advances in this direction was made by the great Swedish botanist Linnæus during the eighteenth century, in his "Systema Naturæ." In his, as in all subsequent systems, the different kinds of plant or animal are termed *species*, though the exact definition of a species is an

exceedingly difficult matter, as we shall later on have occasion to learn. Species are aggregated into larger groups or *genera*, these into still larger assemblages, and so on, until at last we reach the *sub-kingdoms* of Plants and Animals, which together make up the *kingdom of Living Things or Organisms*. The resemblances between members of the same species are so close that all *of them can be readily believed to have sprung from the same stock. But as we go to larger and larger groups the resemblances are fewer and of more general character, while the differences are broader and more marked.*

Scientific Names. We also owe to Linnæus the convenient system of *binomial nomenclature*, by which a double "scientific name" is given to every animal or plant. There are, for instance—amongst others—three common British kinds or species of Buttercup, known to botanists as *Ranunculus bulbosus*, *Ranunculus acris*, and *Ranunculus repens*. In each case the second is the specific name, and the first the generic name, these bearing much the same relation to one another as the Christian and surnames of a man, except that the order is reversed, as in many official lists of human beings. The individuals of the species *bulbosus* resemble one another even in minute details, as do those of *acris* or those of *repens*. And although the members of the three species are in some respects different, they agree in most particulars, so that it is justifiable to place all three of them—together with a number of other species—in the same group or genus—*Ranunculus*—of the next higher order.

Such scientific names are mostly derived from Latin or Greek, or both, these languages being the common property of all civilized nations, and they possess the great advantage that they can be used so as to be universally intelligible. English, German, Russian, and Italian botanists alike understand what plant is signified by the name *Ranunculus bulbosus*, but common or popular names vary so much that endless confusion would be caused if they were employed in scientific works. To absolutely guard against misconception, however, it is necessary to indicate by initials the authority who gave the particular specific name, as the same plant or animal has sometimes received more than one appellation, while on the other hand the same verbal label has been attached to more than one plant or animal, both possibilities being the result of imperfect knowledge of work already done. The complete name of the plant in question is *Ranunculus bulbosus* L., where the initial stands for Linnæus.

Natural Affinities. The older attempts at classification were generally more or less artificial, in that they were often based on superficial characters, which might or might not indicate close relationship. A good example of this is afforded by the old group of backboned animals to which the name of *Quadrupeds* was given, embracing all backboned animals with four legs, tortoises and toads, as well as cows and cats. But the two former are cold-blooded animals devoid of hair, while the other two are warm-blooded, covered with hair, and suckle their young. It may be added that the limbless snake is undoubtedly a relative of the tortoise, and that the whale, which possesses no hind legs, belongs to the same great group as the cow and cat. Anomalies like this were gradually realized, and in the early part of last century "natural" classifications came into vogue, which attempted to group organisms in a less arbitrary way. And it was ultimately perceived that the mutual affinities of groups were best expressed by arranging them in a sort of classificatory tree.

Why classification should assume a tree-like form was not fully realised till 1858, when Darwin and Wallace brought forward their theory of Evolution, the "Origin of Species" of the former appearing the following year. The idea of evolution—of the origin, that is to say, of existing species from pre-existing ones, as against the doctrine of the *special creation* of each and all—was no new thing, and had at various times been brought forward from the days of the old Greek philosophers downwards. Suggestions had even been made as to the way in which it might possibly have come about. But it was reserved for Darwin and Wallace to marshal so large an amount of evidence with such irresistible force that the *fact* of evolution is now no longer seriously questioned by competent authorities. At the same time these two scientists propounded an invaluable theory as to the *means* by which evolution has been effected.

The Influence of "Darwinism." Since 1858 "Darwinism," to use a widely current term, has revolutionized Biology, and exerted a profound influence upon many other branches of learning. Among other things our conceptions of classification as applied to organisms have been greatly modified. For if organisms are actually all of common descent, a new meaning attaches to such words as *affinities* and *relationships*, formerly employed in a vague and indefinite way. The classificatory tree is, in fact, a *genealogical* one, and the more nearly it expresses direct and collateral blood-relationships the more nearly does it approximate to what practically all modern biologists believe to be the truth. The larger branches of the classificatory tree correspond to the larger groups of the organic kingdom and the smaller branches to the subordinate groups, while the final twigs may be taken to correspond to species, and the leaves which these bear to individual plants and animals.

Morphology. *Morphology* (Greek, *morphé*, form; *lógos*, a discourse) is the second subdivision of Biology. Vegetable Morphology is concerned with the form and structure of plants, while the sister department of Animal Morphology has to do with the form and structure of animals. And here a further subdivision is possible, for we have *Anatomy*, which treats of the more obvious facts of structure, and *Histology* (Greek, *histós*, a texture; *lógos*), which brings the microscope to bear upon

minuter anatomical details. Morphologists are not content with merely observing and recording facts, but in all cases attempt to find out *why* things are as they are. To many such questions reasonable answers have already been found, as we shall soon see; but there are innumerable problems which still await solution.

Physiology. The third division of Biology is that of *Physiology* (Greek, *phŭsis*, nature; *logos*, a discourse). Here a distinction is drawn between Vegetable and Animal Physiology, which deal respectively with the uses or functions of the various parts of plants and animals. While the morphologist is primarily concerned with the organic machine at rest, the physiologist studies its actual working. It is, of course, sufficiently obvious that function cannot be studied without some knowledge of structure, while mere anatomy would prove very uninteresting and largely unintelligible if considered absolutely without reference to the uses of the parts of the body.

Development. Development, or *Embryology*, the fourth division of Biology, is concerned with the evolution of the individual, from its first inception up to the adult condition, and is in reality the morphology and physiology of immature organisms or embryos

Applied Biology. The fifth division, *Applied Biology*, has to do with the useful application of biological knowledge to human industries, and naturally falls into the two departments of *Applied Botany* and *Applied Zoology*, both of which are of fundamental importance for Medicine and Agriculture. Applied Botany, again, has a bearing upon industries which are concerned with the employment of vegetable fibre and woods of various kinds, while Applied Zoology is of primary value for the intelligent conduct and proper development of Fisheries, etc

Distribution. The *Distribution* of plants and animals constitutes still another large branch of Biology, and one, too, which is of absorbing interest. If we take either Plant Distribution or Animal Distribution, we shall find that it embraces two closely-related subdivisions, *i.e.* Distribution in Space, or Geographical Distribution, and Distribution in Time.

Geographical Distribution is concerned with facts and theories as to the way in which existing plants and animals are disposed with reference to the surface of the globe. The plants of a given area constitute its *flora*, the animals its *fauna*, and the nature of these assemblages in a given case does not altogether depend upon climate, as commonly supposed. The marked peculiarities of the fauna and flora of Australia; the fact that horses and camels are indigenous only to the Old World, while armadilloes and humming-birds are limited to the New; the extraordinary character of many fishes inhabiting the abysses of the ocean; these and many other matters of the greatest interest present themselves to the student of geographical distribution

Distribution in Time. The solid framework of the globe is largely made up of layers or *strata*, composed of rocks such as sandstone, slate, and limestone, which once existed as accumulations of sand, mud, or the like, on the floor of the sea or of inland bodies of water, and have since been consolidated and upheaved to make part of the dry land. As is fully explained in the section on GEOLOGY, it has been found possible to arrange these strata in chronological sequence, largely by application of the simple principle that when several such layers rest one upon the other the undermost are necessarily the oldest and the uppermost the youngest. Rocks of the kind commonly contain *fossils*, *i.e.* the remains of organisms which formerly existed, or proofs, such as footprints, of the existence of such organisms. We are thus enabled to acquire a large, though necessarily imperfect, knowledge of the ancient floras and faunas of the globe for a period of many million years. Going back in time, we find that formerly existing plants and animals become less and less like those which now exist, while speaking broadly they are of lower and lower kind. The evidence afforded by the "record of the rocks" is conclusive as to the fact of evolution, and the genealogies of some groups of organisms have now been worked out in considerable detail

Higher Problems of Biology. The seventh great subdivision of the subject, *Philosophic* or *Theoretical Biology*, has for its province the consideration of the higher problems which present themselves to the student of Biology, and the construction of theories by which the existing order of things receives intelligent and intelligible explanation. Its data are derived from Botany and Zoology alike

While either Botany or Zoology is divisible into all these subordinate divisions, the latter subject merges into studies of still higher kind. Among these may be enumerated *Anthropology* (Greek, *anthropos*, man; *logos*, a discourse), dealing with mankind; *Psychology* (Greek, *psuche*, soul or mind; *logos*), treating of mind; and *Sociology*, which is the study of human communities. The influence of the Theory of Evolution has made itself felt far beyond even these limits, and has largely modified our attitude towards many other departments of learning, among which Language, History and Theology may be included.

We are now in a position to understand what is meant by NATURAL HISTORY, the subject of this course. It is not so much a subdivision of Biology as a biological attitude. The naturalist studies plants and animals so far as possible in their natural surroundings, or in such a modification of these as may be presented by a vivarium or an aquarium. Although he resorts, when necessary, to the resources of the laboratory or museum, his observations and experiments are made by preference on organisms "at home." He may collect plants or animals with some definite scientific end in view, but does not accumulate dried flowers, birds' eggs, butterflies, or shells, merely for the sake of collecting, as so many persons do

The Aim of Natural History. Natural History aims at determining the relations between organisms and their surroundings or environments, and therefore deals with habits and their meaning. The special names of *Bionomics* (Greek, *bios*, life; *logŏs*, a discourse) or *Ecology* (Greek *oikos*, home; *logŏs*), are often applied to Natural History as used in this sense. Every species is more or less well adapted to its environment, and the study of adaptations offers an inexhaustible field for observation and experiment. The shapes of leaves, the colour and structure of flowers, the varied hues of insects and birds, the structure of a spider's foot or a bat's wing; these, and things like these, all have some adaptational meaning. And our enjoyment of Nature is vastly heightened if we see with understanding eyes.

A competent naturalist must possess a working knowledge of Classification, or he will be incapable of understanding the relation of various groups of organisms to one another. The buttercup, marsh marigold, columbine, larkspur, and monk's hood, for example, are each and all interesting plants, but the interest is increased when we know that they are nearly related, and that the marked differences between them are variations of a common plan, brought about by adaptation to different surroundings. And the same remark may be made of such an assemblage of animals as the rabbit, rat, squirrel, guinea pig, and porcupine.

The naturalist must also be more or less of a morphologist and physiologist. The flight of an insect or a bird, for instance, cannot be properly studied without a knowledge of both structure and function, and an acquaintance with both is equally necessary if he wishes to intelligently understand how a bee rifles flowers of their nectar, or how a pitcher plant catches its insect victims.

The Study of Life-histories. Development also largely falls within the purview of Natural History. It is true that the microscopic details of the processes whereby a full-grown plant is evolved from a microscopic germ, or a frog from a relatively small egg, are the special province of the laboratory worker. But the naturalist can observe the germination of the seed, and the gradual metamorphosis of the tadpole into the frog, or the caterpillar into the butterfly. It may be safely asserted that the study of such "life histories" is among the most fascinating, if not the most fascinating branch of the subject.

With Applied Biology, as such, the naturalist is not necessarily concerned. But should he desire to do work which is useful as well as interesting, there is abundant scope for his energies. The name is legion of the insects and lower plants which infest our cultivated crops and sadly diminish the earnings of the farmer, while our knowledge of them is very imperfect. To study the habits, and carefully work out the life-histories of such forms is the first step towards combating their ravages. And work of the kind requires nothing but patience, conjoined with the power of accurate and careful observation.

Most work on Distribution is beyond the powers and opportunities of the average amateur naturalist. But the careful study of the flora or fauna of a district, or of a particular group of plants or animals, may furnish valuable material for the advancement of this branch of biology. Much remains to be known, for instance, of the distribution of British land-snails and land-slugs. Good local field work can still be done in Britain with regard to Distribution in Time, for the careful collection of fossils from cliffs or quarries is calculated to advance our knowledge. But it is not enough to pick them up from heaps of rubbish. The exact layer or stratum to which they belong must be carefully determined, or energy will be expended almost in vain.

It may be added that the naturalist ought to know the broad outlines of Philosophical Biology, so far as evolutionary principles are concerned. Allusion will elsewhere be made to experiments on heredity which can be carried out by anyone of average intelligence.

It is hardly necessary to insist upon the importance of Natural History as a branch of study which should form part of every education aspiring to be termed "liberal." To take an intelligent interest in the plants and animals which everywhere obtrude themselves upon our notice, is to possess a perennial and inexhaustible source of happiness, to say nothing of the practical value of trained powers of observation and reasoning. And such study goes far to satisfy the craving for the knowledge of "how" and "why" for knowledge sake, which is among the most deeply-implanted instincts of the human mind. It is much to be hoped that the attempt which is now being made to introduce Natural History — under the name of "Nature Study" — into schools will meet with permanent success and yield abundant fruit.

BUILDING

A PRACTICAL AND COMPLETE COURSE IN BUILDING CONSTRUCTION

DEALING WITH BUILDING

FOR ARCHITECTS AND BUILDERS, FROM THE FOUNDATIONS OF ANY STRUCTURE TO THE ROOF

COVERING THE WORK OF

Excavators	Masons	Tilers	Joiners	Electricians
Scaffolders	Slate Masons	Slaters	Plasterers	Painters
Bricklayers	Marble Masons	Plumbers	Smiths	Paperhangers
Paviors	Carpenters	Zinc Workers	Gas Fitters	Glaziers

ILLUSTRATED WITH PLANS, PHOTOGRAPHS, AND DRAWINGS BY WELL-KNOWN ARCHITECTS

CONDUCTED BY

Professor R. ELSEY SMITH, Professor of Architecture and Building Construction at King's College, University of London; Fellow of the Royal Institute of British Architects; Examiner in Architecture to the Board of Education

Professor HENRY ROBINSON, Emeritus Professor of Civil Engineering at King's College, University of London; Member of the Institute of Civil Engineers; and other authorities

MAIN CONDITIONS GOVERNING BUILDING CONSTRUCTION

By Professor R. Elsey Smith

An intimate acquaintance with the various materials used in construction, their nature, properties, defects, and appearance, is an essential qualification for any one who in these days aspires to be connected with either the design or erection of buildings.

It is of great importance to be able to distinguish between good, indifferent and bad qualities of the same material, and to realise that for certain classes of work the materials used must be varied according to the governing conditions, and to feel sure, in specifying materials, that the qualities described are such as can be readily obtained.

Special articles in this work deal with the nature and chemical and physical properties of the various materials used in the building trades, but the student must neglect no opportunities of examining materials in use in actual building, paying where possible repeated visits to works in progress, and noting the result of the use of certain materials. He should endeavour, also, to ascertain the conditions determining the selection of material for a particular purpose in a particular locality.

Materials and Methods. It is true, in these days, that almost any material may be brought to almost any spot; but the cost of conveyance and cartage may form a very heavy item in the value of such goods when delivered. Though the conditions regulating the use of materials give a wider scope in this respect than they did, say, a hundred years ago, it is often important, where building with due regard to economy is to be observed, to be able to examine and select local materials, and to determine to what extent they may be relied upon. Beyond the mere utility, there is also, in many cases, a great pleasure and charm in the use of such materials; a certain local character may often be given to the appearance of a building by their adoption [1].

In dealing with the various trades, the materials in ordinary use will be referred to briefly, the special characteristics necessary for a proper specification will be emphasised, but for more complete accounts of the various materials, the student should consult the special section on Materials and Structures.

Of no less importance than a knowledge of the materials is a proper acquaintance with the methods employed, of so combining them as to form integral parts of a building, and of the completed building itself. This implies an acquaintance with the various processes of very many trades; though no one can expect to become a completely equipped workman in all, it is possible to acquire such knowledge of them as to be able to distinguish excellent and moderate workmanship from indifferent and poor work. Such knowledge is necessary in order to design work that others can execute, or to superintend the work of others, as well as in carrying out the work itself.

Changed Conditions. The conditions of to-day, in relation to building as well as in many other directions, are totally different from those in force in this and other countries for several centuries, during which the magnificent cathedrals and the vast monastic establishments and important public and private works were erected.

Throughout this period the workmen were associated in guilds, according to their trades; they were instructed in their various handicrafts, and worked in association with their fellow-craftsmen, moving often from place to place as work was completed, in considerable bands. The work was arranged for by the master-builder, and the drawing or design, from which even an important building was erected, was comparatively simple and elementary. At this period, the style in which work was executed, though it slowly changed and developed, was at any one period fairly sharply defined, and, subject to the

effect of local conditions, was in general use throughout the country; all the workmen were instructed in the manner of work at the time in vogue, but at the same time much scope was left for the exercise of originality by the individual workman.

Variety in Detail. The result of this system is seen in the work of the mason and carpenter, and, in particular, in the carved enrichments which were such an important feature in the scheme of mediaeval craftsmanship. In any portion of a great church or cathedral, erected at one and the same period, a general similarity of the style of the carved enrichments will be observed; but a closer examination will generally reveal an almost infinite variety in the details of the work. The ideas of each individual craftsman were allowed full play, with the result that in a perfectly harmonious building there is still a splendid variety in the minor parts and great interest is given to the detail.

The conditions of social life and of work are very different in our days. The functions of the designer, or architect, and the actual constructor, have become more completely separated, and for many classes of work entirely so. There is, moreover, at this present time no single style prevalent and recognised as in general use in this country. One result of this is that a workman, while engaged upon one structure, may be required to execute a piece of work in the manner of one of the Gothic periods, and directly afterwards may be transferred to work of a Renaissance character.

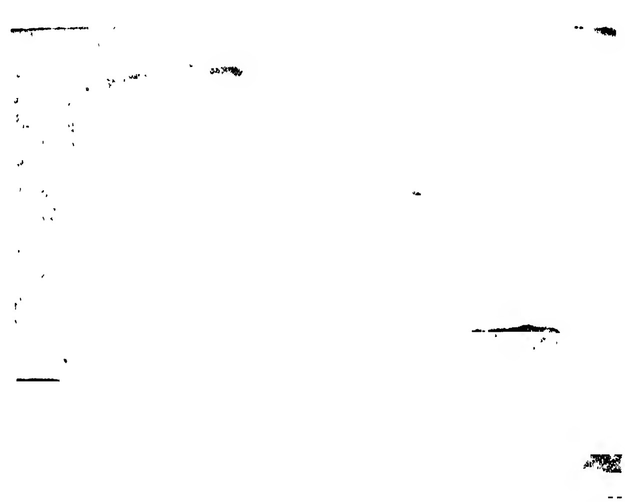
1. THE USE OF TIMBER IN BUILDING CONSTRUCTION: A HAPPY EXAMPLE.

The New Conditions of Craftsmanship. It is not to be expected that, under such conditions, he can possess a complete knowledge of the various details of all the styles in which he may be called upon to work. He depends, therefore, in these days, on full and accurate details being supplied of all work he is called upon to execute; there is, as a rule, but little scope left for the workman's individuality to display itself.

At the present day, too, to a large extent, the custom, especially in London and other large towns, is for a group of workmen to be collected together for the execution of any building, for them to be dismissed as required, and for them to be dispersed on completion of the work. The contractor, or his foreman, may keep in touch with a few of the men who have shown themselves the most capable and trustworthy workmen, and in the builders' own shops good workmen are often retained for many years; but there is nothing resembling the old guilds of craftsmen. The best workmen may still take a pride in a good bit of individual workmanship; but there is rarely room for the corporate pride in a splendid building, resulting from combined effort on the part of a great body of workmen, which must have been a notable element in building under the old conditions which have now passed. The architect, as its designer, however, and the builder who has organised and carried out the work, may take a legitimate pride in the result of their own labour, and of the work of others they have directed. The exigencies of modern conditions have concentrated in one or two individuals the functions formerly exercised by considerable bodies of workmen. Efforts have been made to some extent to revive the old conditions of craftsmanship, and under favourable circumstances they may, in a limited way, be successful; but there seems no prospect of anything like a general return to any such conditions amongst the general body of workers. The whole spirit of the times has changed; the intense desire for extreme rapidity of work, stimulated often by the enormous values attached to sites, the general introduction of machinery into all departments of work, and the facility of transit both for individuals and merchandise, seem entirely to prohibit the re-establishment of

conditions that formerly existed naturally, otherwise than as an exceptional and isolated effort. It is therefore essential, under modern conditions, that those who are to direct the efforts and work of a large or even a small body of workmen should themselves be exceptionally well equipped.

The architect, if he is to be fully worthy of the title, must be possessed of artistic powers and facility in expressing his intentions; but he must, as the basis of his work, understand thoroughly the nature of the materials he is to use, and the capacities of the workmen on whom he must eventually rely for the execution of his projects. The conditions of present-day work require that, for much of his work at least, he should keep himself in touch with all the most modern achievements in the way of construction. In most cases he must be prepared to deal with buildings of various classes, even though his work in the main should be somewhat specialised.

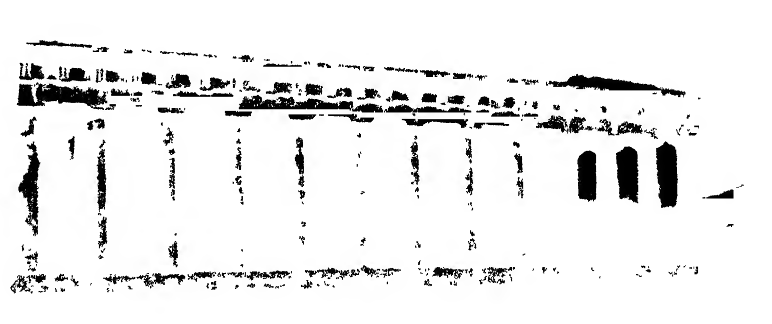


2. THE DURABILITY OF ROMAN MATERIALS: THE TORRE DEI SCHIAVI, ROME, AFTER 1600 YEARS

The Builder's General Knowledge.

The builder cannot be expected, any more than the architect, to become an expert craftsman in all trades; but he must have a general knowledge of them, and should be familiar with the capacities of workmen in various trades and the amount of work that may be properly expected of them. As in the case of the architect, he may be called upon to execute buildings, varying greatly in the purpose for which they are used, and in the system of construction; but he is furnished, as a rule, with detailed instructions in the form of drawings and specification. The builder should share with the architect the desire for the production of a sound and well-constructed building; but from a business point of view it should be his just and reasonable expectation to execute such work with a fair profit to himself. Though these interests may to some extent clash, his efforts should be directed to securing his profits by fair prices, good management and supervision rather than by the introduction of inferior material, the employment of indifferent workmanship, or any other unworthy means.

"Builder" and "Contractor." The term builder is a very wide one. It may be applied to the man who erects small suburban houses as a speculation, either a few at a time or sometimes whole streets of them, and to the man who erects work under contract, often of an extensive or valuable character. The circumstances governing the two classes of work are entirely different, and between these extremes there are many inter



3. THE IMPERISHABLE MARBLE OF THE GREEKS: THE TEMPLE OF THESEUS AT ATHENS, AFTER 2300 YEARS.

mediate grades. The suburban house must be completed to sell or let within a certain sum, if it is to have any chance of competing in the market with its competitors. For the same reason it must be finished in a style to attract those looking out for this class of house. The drains and sanitary fittings must be sound enough to pass what are usually strict and somewhat severe tests. There is often originally a fairly stiff ground rent, which the builder desires usually to "improve," and the margin left for the actual structure is often small. Under these conditions, bricks and timber of inferior qualities are often employed, and the work cut down to its lowest limits; but even in such cases a fairly sound structure may be erected by a capable man.

The builder who executes contract work, often styled also a contractor, works under different conditions. Unless his price is very closely cut, it should allow of a sound structure being erected with a fair margin of profit. Such a building is also usually carried out under the direct supervision of an architect. Usually there is also a clerk of works, whose special duty it is to keep a watchful eye on the materials and workmanship employed. Buildings erected under such conditions should be thoroughly sound and well constructed.

Cost of Structures. The cost of structures for which the best materials and workmanship are provided will necessarily be high, but such a building may be expected to prove economical. Even with the lapse of a considerable number of years little repair should be necessary, if careful attention is given to the construction, whereas in cheaply constructed buildings defects very quickly show themselves. But the best materials, almost without exception, are subject, when exposed to the various conditions of the weather, to gradual decay, especially in certain circumstances; and almost every building requires more or less watchful care to preserve it in its original perfect state. Some few buildings, it is true, have been constructed so as to defy the tooth of time, and but for accident or vandalism would have been handed down to our day almost perfect. Such are some of the best buildings of the Egyptians, the Greeks, and the Romans. In all such cases this exceptional result is due to the use of materials which in the climates in which they were employed prove to be almost indestructible. For example, the granite of the Egyptians, the marble of the Greeks [3], and the wonderful concrete formed with Pozzuolana of the Romans [2], have under favourable conditions remained to the present day in such perfect preservation that the very tool marks are still visible. In our northern climate, with its humidity and great variations in temperature, including at times prolonged frosts, even the same materials, subjected to a different set of conditions, would not have had the same permanent character.

Influence of Climate on Materials. In other countries, where the conditions of building were different, and where materials of a less permanent nature were employed, examples are afforded of the utter destruction that may follow neglect. The splendid palaces of the Assyrians and Chaldeans, which in their day were perhaps hardly less magnificent in their effect than some of the great structures of the Romans, were in the main built of sun-dried bricks, arranged in immensely thick walls and faced, both internally and externally, with materials better able to withstand the effects of the weather. Such a compound structure, with an extremely destructible core, and a comparatively thin skin of a more permanent character, may be maintained in good repair by unremitting attention; but when once this is withdrawn, the destruction is rapid, and these great palaces are marked in these days by shapeless mounds of earth, from which, however, the care of the explorer has extracted many of the secrets of the original structure.

These historical examples are recalled because they emphasise the great influence climate has upon materials, and the necessity for a thorough knowledge of this subject to the practical constructor of buildings. Even in our climate it might not be impossible to erect a building that would defy the attacks of weather; but it would be costly and could not be carried out on a large scale. Anyone who has charge of a considerable building, even though thoroughly well constructed of good but customary materials, soon becomes aware of the many quarters from which the permanence of the structure is liable to attack. Many, if not all, of our great cathedrals, for example, employ a small permanent staff of workmen, who are constantly engaged in the examination of the structure, under skilled supervision, and in the repair of the minor defects and decay that are constantly showing themselves.

Situation and Soil. No ordinary building, therefore, however well selected are the materials originally employed, can be trusted to stand for any lengthy period without attention. But the better they are and the sounder the construction, the less costly will be the inevitable work of maintenance and repair.

It may be pointed out incidentally that the very usual system of leasehold tenure has a considerable influence on the class of work commonly executed. The fact that a building, after a certain lapse of years, reverts to the ground landlord tends to prevent the erection of structures calculated to last for all time. It is held sufficient in many cases to put up such a structure as will, with ordinary attention, last out the term of the lease.

The situation of a building and the nature of the soil upon which it is erected, are further important elements in determining its durability and stability, and have often an important influence on its cost. The considerations affecting the locality of a building are various, and differ with different classes of buildings. For some few buildings a site is selected with great care, attention being paid to the aspect, the elevation above the sea, facility of access,

and similar matters, of the utmost importance in securing the health of those who are to make use of it. Such buildings usually belong to the class of hospitals, or asylums for the young or the aged, in which, within certain limits, the necessity of obtaining the most healthy situation possible, is paramount. The same is true also of private residences of a very high class

Considerations which Affect Locality. But other considerations regulate the locality of most buildings. As a rule, in the case of buildings erected for business purposes, facility of access by road, or rail, or river is a paramount consideration; in other cases the fact that a particular trade is limited to a certain district narrows the choice

In the case of public buildings, they must generally be so situated as to be in the neighbourhood of important business centres already created; in the case of dwellings for the working and middle classes they must, as a rule, be within a certain distance of their daily work.

In recent years, modern facilities of transit have had, and will have to an increasing extent as these facilities develop, a remarkable influence on this question; even for workmen of the poorest class it is becoming increasingly possible to convey them between the site of their daily labours and their homes, which may be a dozen or a score of miles distant, rapidly and cheaply. For the upper middle class, rapid railway travelling and motors are rendering districts available for residential purposes, which a few years ago would have been held to be much too far afield for those whose business or profession required daily attendance at a city office

The locality may have an important effect on the durability of a building; a low lying district, especially if marshy or adjoining a large body of water, is particularly liable to mists and damp fogs. Such a site may necessitate preliminary drainage operations, and special precautions in providing against damage from the effects of moisture, which tends to promote decay. On the other hand, a site exposed to continuous high winds in any sandy district is liable to have any stone-work attacked and slowly eaten away by the fine particles of sand carried against it. This has occurred on parts of our Eastern coasts. Generally speaking, sites somewhat open to the access of sunshine and drying winds are favourable to the preservation of materials, as they are to the health of the inhabitants.

Factors which Affect the Cost. The locality and the actual site may, as we have seen, very materially affect the cost of any structure to be erected upon it. Apart from the actual cost of dealing with difficult foundations, the facilities for access of materials, or the reverse, make a very serious difference in the cost of executing work. In almost all cases materials have to be brought for a longer or shorter distance to the site, and it is not merely the actual distance, but the amount of handling goods require, that determines the cost.

The loadingin to railway trucks or barges is a somewhat costly process for goods of large bulk and small value—*e.g.* sand, ballast, bricks; and if goods have to be subsequently transferred before finally unloading the cost is very rapidly increased. The existence of a hill necessitating the employment of a chain horse, or in cities the necessity for carrying out all soil from excavations in baskets, and often its conveyance to a distant spot before it can be deposited, are other examples of the manner in which difficulties, and consequently the cost of work, may be enhanced. Any attempt to arrive at the actual weight of materials employed, in a building of even moderate size, will make it easy to realise how such questions materially affect the cost

The nature of the actual soil upon which a building is to be erected is a matter of the greatest importance. The method of dealing with difficult sites will be dealt with in due course, but it is desirable to realise, in this preliminary stage, that, while it is possible to deal satisfactorily with the most difficult conditions, it is in many cases a matter of very great trouble, and, as a consequence, of increased cost. Much will depend on the character of the building to be erected. If, for example, it is in itself lofty, and consequently places a great load on the foundations or, even if of moderate height, if it is intended for warehousing very heavy goods, or for the reception of heavy machinery, special precautions must be taken to meet these conditions

Foundations. The best foundations are provided by materials that are practically incompressible, or which, if liable to compression, will yield uniformly. The principal foundations of this class are rock, hard gravel, and hard clay, certain others, such as loose gravel and sand, are in themselves practically incompressible, but require to be so confined as to prevent the possibility of lateral movement

Many other soils, such as ordinary clay, alluvial deposit, and all kinds of made ground, are liable to compression. Some of them are also liable to alteration in bulk, involving sometimes expansion as well as contraction, under varying atmospheric influences. Clay is particularly liable to such changes, and will be affected to an appreciable extent by either a prolonged drought or continuous heavy rainfall, this effect extending to a considerable depth below the surface of the ground.

A difficult class of site to deal with is one in which part consists of compressible and part of incompressible materials. This not infrequently occurs in the neighbourhood of London, where gravel and clay are met with

Another danger to be apprehended, in the case of natural foundations which contain much moisture, is the possibility that they may at some future time be drained by operations carried on at a different level. This brings about the withdrawal of water from the soil, with the result that the bulk of the soil will be contracted and will be followed inevitably by the subsidence of the superstructure.

The Selection of a Site. The methods of dealing with these difficulties will be described in the proper place, but we may point out here the importance that is often attached to the character of a building site, and the desirability of carefully selecting it when opportunity for doing so arises; and, in cases where the site is fixed by other considerations, the necessity of a very careful examination of it with a view to dealing with any difficulties it may present. It is well, from the first, to emphasise the fact that in dealing with the site and the means required to safely carry a building to be erected upon it, nothing that can be done to counteract all chances of future failure should be omitted.

It may well be that where the money that can be spent on a building is limited, the provision of an adequate foundation on a difficult site may involve a somewhat painful economy in dealing with the superstructure; but that is on all grounds to be preferred, to erecting a striking superstructure on an ill provided foundation, with the possibility of future disaster involving serious loss to the owner and damage to the reputation of the constructor.

One thing is quite certain—that whatever may be the cost of properly preparing a site in the first instance, it will prove immensely more costly, should a partial failure subsequently occur, to deal with the site then so as to adequately maintain the building.

Aspect. A matter that should not be lost sight of in selecting a site and arranging for covering it with buildings is that of aspect, which in some cases is of great importance.

For all purposes for which it is of importance to secure as uniform a quality of light as possible throughout the working day, an aspect north, or, better still, some few points east of north, is desirable. Windows having such an aspect will, at no time during an ordinary working day, receive any sunshine, and if somewhat east of north will not do so, even if work is carried on late in the long summer evenings.

In cases where the healthiness of a building is an important factor—and this includes all domestic buildings—it is desirable to secure sunshine at some part of the day to all windows, except those lighting rooms which it is essential to keep cool, such as larders, dairies, and similar rooms, for all of which a northern aspect is preferable. Where a site is considerably larger in area than the building that is to occupy it, there should, as a rule, be no great difficulty in securing a suitable aspect for most of the rooms, unless some natural features, or the fall of the ground, should create one. But in confined sites, such as are usually found in towns, especially in the case of terrace houses, where the front rooms are lighted from the street, and the back rooms from the back portion of the site itself, the comfort of the house will depend to a great extent on the relation of the site to the adjoining street.

The Best Streets to Live in. Streets running north and south are better for living in than those running east and west. The former secure sunshine to both the front and back windows during some portion of each day, while in the latter the windows facing south, whether at the back or front of the house, will receive a large amount of sunshine, while the northerly windows will receive none.

Some of the considerations that are likely to materially affect the operations of the builder have been touched upon, but the subject is one that can hardly be exhaustively dealt with, the circumstances varying so greatly with individual cases. But enough has been said to emphasise the importance of taking into consideration the effect that the site and its situation may have on the builder's operations. Where an architect is employed, such matters come first under his consideration, and are provided for by his disposition of the building, and by its structural arrangement. But they are matters that will require the careful attention and consideration of the builder in many circumstances.

The Building Trades. Future articles will deal with the various trades by which the work of the builder is carried out. These are divided into two principal divisions—those relating to the carcase of the building, and those dealing with the finishing of the building.

The first division begins with the work of the excavator who prepares the site and the foundations and deals with the drainage. He is followed by the bricklayer and mason, and at an early stage of the building the carpenter appears upon the scene, and the tiler or slater, with the help of the external plumber, covers in the building after the carpenter has completed the framing of the roofs.

When the building is covered in, the finishing work begins. The trades which work on the finishings are those of the joiner—who, as a rule, provides doors and windows to close the various openings before proceeding to other internal work—the plasterer, the smith and ironmonger, the internal plumber, the painter, and the paperhanger and glazier.

This order represents the general sequence of a specification and roughly the order in which the trades are employed in most buildings, but to a great extent the work of the different trades is intermixed, and the builder has to arrange for the work of one trade following on another in different parts of the same building without delay or intermission.

In these days a great many specially-manufactured articles are employed in a building, many of them patented, and as far as possible they will be dealt with in considering the trades within whose province it falls to supply and fix them.

THE MASTER-BUILDERS OF OUR COMMERCE

By A. J. Windus

IN olden times men who had amassed great wealth as the result of their trading ventures were called merchant princes. Their modern successors are commonly styled captains of industry.

The distinction is not without significance. In it there lurks a subtle indication of great changes which have taken place in the domain of commerce—changes which have had far-reaching consequences. But we cannot understand these changes, nor can we apprehend the part we are to play in the business life of to-day, unless we revert to the springs of commercial intercourse at the dawn of civilisation.

The Beginnings of Commerce. Our remote ancestors were savages who roamed the forests in search of prey, or waged fierce warfare among themselves to settle the claims of rival chieftains. It is difficult, perhaps impossible, to fix the exact period when they emerged from barbarism. Long before the Christian era, however, the Phœnicians made voyages to Britain to dispose of their products, taking in exchange tin, lead, and skins. Their transactions were effected without the aid of money; there was a direct exchange, that is to say, of certain products for others. This system of trading is termed *barter*, and it marks the first stage of civilisation in a community.

The frontispiece of the SELF-EDUCATOR, Lord Leighton's picture, "Phœnicians Trading with the Early Britons on the Coast of Cornwall," conveys a very clear idea of the way in which business between our forefathers and the Phœnicians was probably conducted. Facing the picture we notice on the left hand side a group of fair haired Britons. One of them bears on his shoulder a sheepskin, which he evidently wishes to barter for the splendid piece of cloth, dyed the true shade of royal Tyrian purple, in which the ladies of the group appear so deeply interested. Now observe the group of Phœnicians on the right, especially the shrewd expression on the face of the merchant who, with hands uplifted, seems to deprecate with a sort of good natured astonishment the notion that such cloth could be had in exchange for a beggarly sheepskin. Notice, too, the vases of metal cunningly displayed in the foreground. We have a perfect conception, on coming away from this picture, of what constitutes barter in commerce.

Civilisation and Commerce. Civilisation and commerce are inseparably linked together, and the one cannot long exist without the other. This law holds good in all countries, and in all ages. It was true of the Babylonian Empire; it is no less true of the British Empire to-day.

We may define civilisation as a state of human society in which intellect supersedes brute force. From this source flows the triumph of peace over war, and directly men have learned in some measure to live peaceably with their fellows, civilisation has begun. In its infancy, it will progress but feebly. As it reaches maturity, and aided by commerce, one of its most powerful auxiliaries, we may expect it to advance with giant strides.

All this applies with undiminished force to the history of our own country. We have seen that even prior to the landing of Julius Cæsar on our shores in 55 B.C., the inhabitants possessed a rude form of civilisation. Its progress was doubtless retarded by the frequent invasions and tribal wars to which the country was subject, perhaps also by the despotic rule of the Druids. When the Romans came, they overthrew this old civilisation, and imposed their own in its stead, and Britain became a Roman colony.

How strange it seems that this happened almost by accident! Rome's foreign policy of that day was conservative rather than aggressive, and what first attracted the Romans to Britain was the desire for pearls rather than conquest. The pearls, though abundant, were inferior and of little worth, but the Roman legions acquired for their master one fair jewel, and that was this land of ours, "the precious stone set in the silver sea."

Basis of Our Merchant Law. The influence of the Roman occupation upon our national life has proved ineffaceable. Its stateliest monuments do not consist in the famous military roads which the Romans constructed, nor in the remains of city walls like those of London and St. Albans, nor in any of these things. They consist in the large number of words of Latin origin which the Romans added to our language, and in the imposing fabric of Roman Law which they built up. Although this did not remain intact, its substance entered largely into all our future codes. Thus the section relating to trade customs and requirements became the nucleus of the Law Merchant, or *Mercantile Law*, whose provisions govern the transactions of all classes of business men to-day.

The Roman legions retired finally from Britain in A.D. 420. In a few years the Saxons came, and were joined about a century later by the Angles. Gradually these two nations became one, the people were called Anglo-Saxons, and their country England. In the early part of the ninth century the Danes began to raid the English coast. Like the Anglo-Saxons, they ultimately obtained a settlement in Britain. To cope with these freebooters, King Alfred built and equipped a number of war vessels, and thus originated the British Navy, the visible protector of our oversea commerce. Alfred died in the year 901. Because of his immense contribution to the welfare of his country, history has conferred upon him the surname of "the Great," and never was a title better bestowed. The incursions of the Danes continued long after Alfred's death, but some time previous to the Norman Conquest the fusion between the Anglo-Saxons and the Danes had become so complete that they were all regarded as one united Anglo-Saxon people.

Trade in Saxon England. The records of Saxon commerce are few and meagre, but one of the statutes of King Athelstan, wherein it was decreed that the merchant who had made three long sea voyages should be ennobled, shows the esteem in which persons engaging in foreign trade were held. The Norman Conquest of 1066 deserves more than the fleeting notice we can give it. Its first fruits were evil. Untold misery became the lot of already unhappy people, who found the harsh yoke of the existing Feudal System riveted more firmly than ever upon their necks. The development of commerce was arrested. But there is another side to the picture. The superior civilisation of the Normans was grafted on to the English stock. Saxons and Normans coalesced, and finally there was produced that "happy breed of men" of which Shakespeare was to write.

The national character was a harmonious blending of the qualities peculiar to the several races who had formerly overrun the land. The Romans, for example, had inculcated respect for law and order. Among the Saxons, Christianity had asserted its benign influence, and fostered the love of justice and fair play. The thirst for maritime adventure sprang from the Danes, while the Normans had transmitted a desire for the arts and refinements of civilisation. These types were reproduced in the nation at large.

Royal Enemies of Commerce. We have now traced the principal elements of which the English nation is compounded. Before passing from the twilight of the Middle Ages into the broad daylight of our modern times, let us gaze for a moment on the state of commerce in the former period. For some time, the Jews were the chief, though not the sole traders. They also engaged largely in the business of money-lending, at high rates of interest. Their wealth and extortionate practices made them objects of envy and hatred, and in the reign of Richard I. many of them were massacred and their [illegible] plundered. The Jews suffered further persecutions in succeeding reigns, and Edward I., in 1290, banished them from England. Any benefit which might have accrued to the non-Jewish trader from this policy of exclusion was, however, more than counterbalanced by the arbitrary interference of monarchs with the natural course of trade. Grievous burdens and restrictions were laid on importers and exporters alike. Three instances will suffice:

1. All through the reigns of Edward I., Edward II., and Edward III., goods for export could be sold in certain places only, sometimes here, sometimes on the Continent, and these places were constantly changed at the caprice of the king.

2. During the reign of the first Edward a decree was made, and remained in force for twenty-eight years, that foreign merchants entering the country were to sell their goods within forty days of arrival, and were not to stay longer except by special licence.

3. When Edward III. engaged in naval warfare he issued press-warrants, under which merchant-vessels were forcibly seized wherever they were found, and added to the king's navy.

Growing Freedom for the Merchant. Internal trade was chiefly carried on by means of fairs. When the king wanted money, special fairs were proclaimed. One would be set up in

a certain district, and all the shops and markets within a greater or lesser radius would be deserted for the time being, while the traders would take their wares to this fair, where they were obliged to pay all sorts of taxes and impositions, for the benefit of king and nobles. Under the guise of tolls, they were also robbed on the way thither by the barons through whose lands they had to pass. Sometimes a national fair was proclaimed, at which these exactions were repeated on a larger scale. During its continuance, not only shops were closed, but all the local fairs throughout the kingdom.

In spite of all obstacles, however, the genius of the people for commercial enterprise began to assert itself, and would not be denied. The growing power of the famous Hanseatic League, of which we shall learn more hereafter; the discovery of coal; the invention of the mariner's compass at the beginning of the fourteenth century; the creation of a native gold coinage, the use of *Bills of Exchange* to which traders had become accustomed under the tuition of Jewish and Lombard merchants; the encouragement given to Flemish weavers to settle in the kingdom; the abolition in the law courts of pleadings in a foreign tongue—these, together with many other causes, combined to check the forces of tyranny and restraint, and gave a powerful stimulus to the spirit of commerce.

A Mighty Edifice. It is not within our scope to continue our study of commercial history beyond this point. We have been present in thought when the foundations of our commercial prosperity were being laid, and we can form some notion of the superb edifice which has been raised upon it. Although we cannot ignore entirely the work of master-builders of past generations, our examination of the mighty superstructure which has risen upon their foundations will be confined chiefly to its aspect in the present day, and to the latest methods and machinery employed in its enlargement and improvement.

One last remark on the older portions of the structure is necessary, however. The English were engaged alone upon it for a long time—until the death of Queen Elizabeth in 1603. In that year, James VI. of Scotland became James I. of England. The crowns and peoples of the two countries were united, and thenceforth English and Scottish merchants laboured side by side upon the stately fabric of British commerce.

If merchants are the master-builders of commerce, we may affirm that clerks are their apprentices and journeymen. Formerly, when an apprentice had served his time and mastered his craft, he was styled a journeyman. To fit the apprentices of commerce for journeyman's work—to teach the junior clerk, in other words, the duties of his own grade and of all superior grades of clerkship, and to instruct clerks generally—is the task which lies before us. It is our business to bring before our readers the clerk's great opportunities, and to help him, as best we may, to realise them.

Synopsis of the Course. It is intended that this course of study shall be of real value in the first place, to one who is at the outset of his career, giving him a clear idea of the openings to commercial life and helping him to qualify for steady advancement from the ranks. But the course will appeal to many who have already acquired a good knowledge of the rudiments of office-work, and who need instruction of a more advanced kind, or who wish to specialise in some department to which their tastes or talents incline them. Of such a little patience is demanded when they find that early chapters treat of the duties of the office boy and junior clerk, or explain the elements of bookkeeping, and all students are advised to become familiar, without loss of time, with the vocabulary of commercial terms and phrases which precedes this introductory chapter. There will be articles, as the course develops, dealing with more complex accounts and with the various instruments of commerce.

Consideration of the theory and practice of double-entry, of self-balancing ledgers and adjustment accounts, of balance sheets and profit and loss accounts will provide material for study on the part of those who wish to master modern bookkeeping. The application of this knowledge by clerks in representative business concerns will naturally be dealt with, and there will be full chapters on import and export trade and foreign exchange. Another article on the importance of specialisation gives valuable suggestions as to lines of study to that end, and factory accounts and Prime Cost Systems, will find their due place. Large numbers of young men are engaged as ledger clerks, cashiers, and secretaries to limited liability companies, and for these company accounts will be carefully treated, the relation of statutory to financial books explained, and the duties of company secretaries set forth. Those seeking guidance in accounts which must be prepared in a form prescribed by law have not been neglected, and there will be also a chapter for audit clerks, articles on the Stock Exchange, and a chapter dealing with confidential clerks.

The Clerk's Prospect. But the subjects do not exhaust the interest of this course, for not only will the student be informed of standard text books, by means of which he may deepen his knowledge, but the SELF EDUCATOR contains sections having an important bearing on his professional education, which he should carefully follow.

The clerk who has had a fair education, and will take pains to improve it, whose integrity and perseverance are undoubted, need place no limit to his career in commerce. His ambition may carry him higher than clerkship. But the importance of steady application must be insisted on. The manager, or principal, who is looking for a man to promote, will more readily recognise the claims of one who devotes some of his spare time to study, and whose progress is punctuated by success in such examinations as are open to him.

INSTITUTE OF CHARTERED ACCOUNTANTS IN ENGLAND AND WALES. Preliminary	None	London, Birmingham, Manchester, Newcastle-upon-Tyne. June and December	Generally the same as in No. 1 Preliminary, but Elementary Latin required, and Euclid Books I to IV	Generally the same as in No. 1 Preliminary	£2 2 0
Intermediate	Dependent upon age when articled	London. May and November	Bookkeeping and Accounts (including Partnership and Executorship Accounts), Auditing, Rights and Duties of Liquidators, Trustees, and Receivers.	None	£2 2 0
Final	Dependent upon age when articled	London. May and November	Same as Intermediate and in addition Principles of Bankruptcy and Company Law and Law. Principles of Mercantile Law and Law of Arbitrations and Awards.	None	£2 2 0
INSTITUTE OF BANKERS			See Banking Section		
LONDON CHAMBER OF COMMERCE.† Junior.	None	London and Provincial Centres. Evenings in May and June.	English Grammar and Composition (including Handwriting, Dictation, Spelling, Essay and Analysis, Arithmetic (including Mental Arithmetic), Tots, (Metric System), a Modern Foreign Language, comprising Translation, Dictation, Composition and Conversation. Commercial Geography and History, Elements of Political Economy.	Generally as in No. 1 Preliminary; from two to four subjects may be taken. Bookkeeping in addition.	2s 6d per subject.

Examining Body and Grades	Age Limits	Time and Place of Examinations	Subjects of Examinations: Obligatory	Subjects of Examinations: Alternative or Optional	Fees
LONDON CHAMBER OF COMMERCE † Senior	None.	London and Provincial Centres Evenings in May and June	English Literature, History and Geography, Foreign (including Oriental) Languages, Mathematics, Commercial History and Geography, Elements of Political Economy	Two of these: Mathematics (including Trigonometry), Methods and Machinery of Business, Banking and Currency, Commercial and Industrial Law, Bookkeeping and Accountancy, Chemistry, Drawing, Shorthand, Typewriting	[illegible]
SCOTTISH CHARTERED ACCOUNTANTS GENERAL EXAMINING BOARD. Preliminary	None	Edinburgh, Glasgow and Aberdeen June and December	Dictation, English Grammar and Composition, Arithmetic, Elementary Algebra, Simple Equations	Three of the following: British History, Geography, Euclid Book I, Shorthand, Latin, French, German	[illegible]
Intermediate	Dependent upon age when apprenticed	Edinburgh, Glasgow and Aberdeen June and December	Mathematics: Arithmetic, Algebra (including Quadratics and Logarithms), Bookkeeping, Framing Accounts and Trust States [illegible]	None	[illegible]
Final	Dependent upon age when apprenticed	Edinburgh, Glasgow and Aberdeen June and December	Law of Scotland, Actuarial Science, Political Economy, Accountancy	None	[illegible]
SOCIETY OF ACCOUNTANTS AND AUDITORS Preliminary	None	London, Manchester, Edinburgh, Dublin June and December	Arithmetic, Dictation, English Grammar and Composition, English History, Geography, Algebra (including Equations and Fractions), Euclid Book I, Two of these languages: French, German, Latin, Elementary Easy Translation and Questions in Grammar	None	[illegible]
Intermediate	None	London, Manchester, Edinburgh, Dublin June and December	Bookkeeping and Accounts, General Commercial Knowledge, Adjustment of Partnership and Executorship Accounts, Law relating to Partners and Executors, Rights and Duties of Liquidators, Trustees and Receivers	None	[illegible]
Final	None	London, Manchester, Edinburgh, Dublin June and December	As in Intermediate with Auditing, Mercantile Law, Law of Arbitrations and Awards, Company and Bankruptcy Law.	None	[illegible]
SOCIETY OF ARTS Elementary	None	London and Provincial Centres Evenings in April	Handwriting, Shorthand, Elementary Bookkeeping, Commercial Arithmetic	Commercial Geography, French, German, Spanish, Italian, Typewriting	[illegible] for first and 1s. for each additional subject
Intermediate	None	London and Provincial Centres Evenings in April	Arithmetic, Bookkeeping, Précis Writing, Shorthand, A Modern Language	English, Commercial History and Geography, Typewriting, Economics, Modern Languages including Oriental	2s. 3d. per subject
Advanced	None	London and Provincial Centres Evenings in April	As in Intermediate	As in Intermediate with Commercial Law and Accountancy, and Banking	2s. 6d. per subject

* To have passed the Matriculation Examination of London University is accepted as a proof of ability and exempts a student from the Preliminary Examinations of most professional bodies. In a modified sense the same is true of the Local Examinations conducted by any of the Universities. The newer Universities attach increasing importance to the business side of education, and, in particular, the University of Birmingham confers Degrees in Commerce.

† Students residing out of London should ascertain if Examinations are conducted by the Chamber of Commerce nearest to them.

COMPETENT AUTHORITIES IN ALL DEPARTMENTS

STITCHING AND ALL ITS VARIETIES ILLUSTRATED

By Azeline Lewis

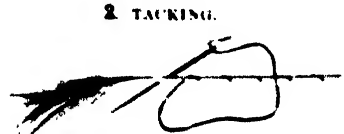
BEFORE we can reach the ornamental stages of dressmaking it may be as well to run over the different stitches which go to build up that rare commodity so dear to a woman's heart a perfectly fitting gown.

Basting or Tacking-out Stitch. This stitch is used for fixing the pieces of lining and material together. It is worked upwards, with the needle placed horizontally and pointing to the left [1].

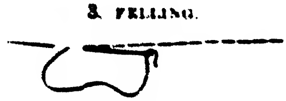
Tacking. This is used to fasten the bodice seams together, and to mark straight lines, centre of bodices, darts, and for portions of skirts, securing down a hem before stitching, and, wherever necessary, to unite two portions to keep them from slipping before finishing off. It is made by passing the needle and cotton in and out of the material in a horizontal direction, taking up a small piece of material and passing over a larger piece. Sometimes the stitches may be fairly long, but the size of these depends on the portion tacked. If there is any strain, as in bodice seams, the stitches should be fairly close, like coarse running, and an occasional back stitch will prevent any slipping apart [2].

1. BASTING

2. TACKING.



3. FELLING.



4. STITCHING.

Felling. Felling is the same as hemming, except that the needle is inserted at the top of the fold instead of at the bottom. It is used for neatening seams, facings, etc. [3].

Running. In this stitch the needle is passed horizontally in and out of the material, in the same way as tacking, only much closer together and at equal distances. Several stitches are done at once.

Stitching. In stitching the needle is also used horizontally to take up a small piece of the material. The next stitch is of equal length, and must be taken right back to meet the stitch last made. Each stitch should be taken over the same number of strands of the material, so that the stitches are perfectly regular [4].

Back-stitching. This is similar to stitching, only the needle is put half-way back to meet the last stitch, instead of right back to where the needle was taken out. It is, however, generally used to mean running with an occasional stitch half way back. It keeps the running or tacking firmer.

Overcasting. This stitch is used not only to neaten the raw edges of seams, but also to prevent them from fraying after they have been cut away and notched as in a bodice. In the former, the stitches are taken over the edge in a slanting direction, a little distance apart, the needle being used from left to right. All the stitches must be of equal size; but as some materials are much worse than others with respect to their fraying capacities, judgment must be exercised as to the depth the needle is inserted in the material. The thread should not be pulled too tightly, or it will cause the seam to drag and prevent it setting well [5].

Loop-stitch. Loop stitch is also used for neatening the seams; but it is not quite so good as overcasting, and must be done fairly loosely, so as not to drag at the edges. The same stitch is used in working silk loops for fastenings over the bars of silk [6].

Slip-stitching. This is a stitch used in dressmaking to fasten down, invisibly, folds, collar and cuff-facings, etc. It requires care in working, and the material should be held lightly but firmly, particularly in the case of velvet, as the pile would be much injured if held tightly. Turn down the fold—if a hem, and not already done—thread a fine needle with fine silk to match the material, slip it in so as to take up only a thread or so of the material under the fold,

draw out carefully, and insert the needle along the turned-up part, and just inside the edge of the fold, so that the stitch will not be seen; draw out and again take up a thread of the material, and so on till the hem or facing is done. If worked carefully, no sign of stitching will be visible. The needle is passed from right to left [7].

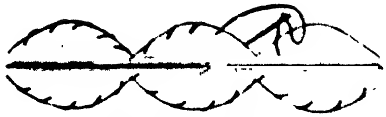
Herring-boning. This is used to fasten down raw edges to make them set flat before putting on facings, etc., and also in some thick materials to take the place of hemming.

If used to fasten down two pieces of material, it is not necessary that the stitches which come on the fold should be carried through both thicknesses of material. It is worked from left to right, the raw edges towards the worker, each stitch being a little distance from the other so that they cross each other, as in the diagram. As this is only used for keeping down edges it need not be as closely done as in plain needlework, and the thread should not be pulled too tightly [8].

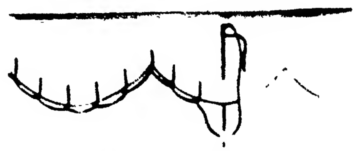
Faggoting. This stitch is now so much used for uniting strips of lace, ribbon, etc., and in many and various ways in the making of fancy yokes and cuffs for transparent blouses, that it must now be included in dressmaking stitches.

In diagram No. 1 we see that in working the stitch the needle always points downwards, also that at the top of the opening the thread lies to the *right* of the needle, at the bottom—illustrated by a broken line—it is to the *left*.

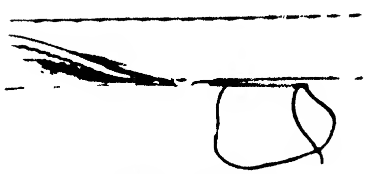
This sketch gives cross-cut bands as the medium, which must be turned in evenly to face and well pressed, and in the case of stiff material they must be tacked at the edges. The tacking should be closely done, or the bands will get dragged out of shape [9].



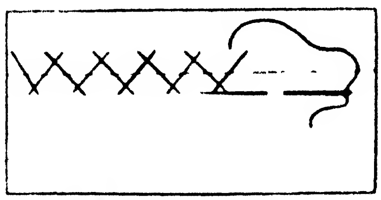
5. OVERCASTING.



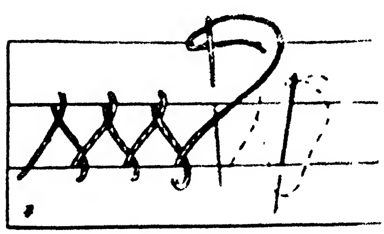
6. LOOP STITCH.



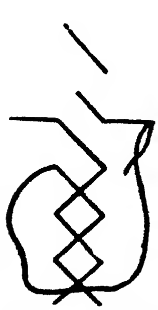
7. SLIP STITCHING.



8. HERRING BONING.



9. FAGGOTING.



10. CROSS-STITCH.

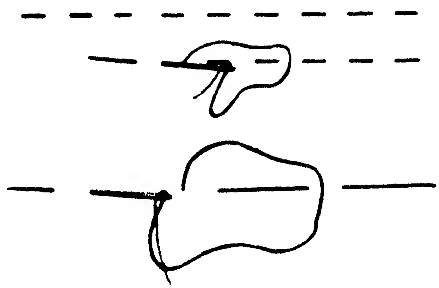
11. FAN-STITCH.

Cross-stitch. This is much the same as that used in embroidery, except that it is larger, and is worked with twist. It is used to fasten the tight band to the bodice, also to mark centre band of skirt. The working can easily be seen from the diagram, and each stitch should be three sixteenths to about a quarter of an inch long. Large cross-stitch is used to fix on tight bands, the stitch, however, only forming one large cross the width of band, and the centre threads are caught together several times to keep them firm. The needle in the upper and under threads of large cross stitch must each time be passed under the bone or steel of the bodice to keep it firm [10].

Fan-stitch. This stitch is used to fix the bones, or steels, firmly to the seams of bodice. Thread the needle, which should be a strong one, with the twist, pass it under the bone to the front, and through the hole made in this, as described later on in the directions for bodice. Make a long stitch of twist in the centre, bring the needle again to the front through the same hole, then work another stitch to the right a little shorter and lower, bring the needle again back through the same hole at bottom and work another to the right of that last made, but a little lower. Make two more on the left of the same length, starting each from the same hole, then bring the needle back to the front, pass it, eye foremost, through the stitches at the stem to hold them in place, put needle through to underside, fasten off firmly, and cut off twist. In some cases it is as well to make seven instead of five stitches when fanning the bones [11].

Gathering. This may be done in two ways: either with the short running stitch, or by taking up a small piece of material, and

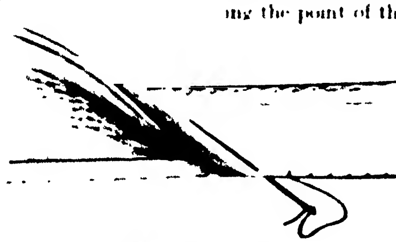
passing over a larger space. The former is used for gathering frills, and anything where the gathering must be close and even, the latter where much fulness is to be put in a small space, as in the waist part of full skirts, and particularly at the centre back, where the greater part of the fulness must be arranged. In this latter form of gathering you take up, say, one-eighth of an inch of material and pass over a quarter to half an inch according to requirements, the gathering, of course, being done on the right side of material. In ordinary gathering the needle should be held quite steady, and the material fulled on to it. For thin materials a long needle is best, so that a good many stitches may be done at a time in order to get over the ground quickly. If two or more rows of gathering be needed, each stitch must be exactly even with the one above [12]. Gauging is another term for gathering.



12. GATHERING.

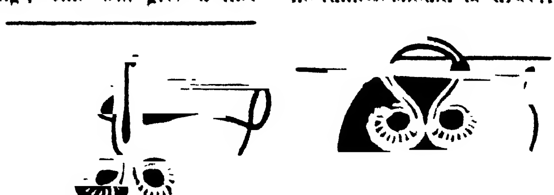
Shirring. This is the term given to several parallel rows of gathering, either plain or done over a fine piping-cord.

French Hem. This is sometimes used to finish off the edges of crossway flounces, and to make them stand out well. To do this, fold over about three quarters of an inch from the edge on the right side of the crossway strip (see that this is even and does not twist), then run along quite close to the edge of the fold just made. Now turn in the extreme edge on the wrong side about a quarter of an inch, and hem down to the ridge made by the running; this will give a nice rouleau hem on the right side, which should not be pressed. When cutting for such a frill about half an inch extra should be allowed for the turning for hem [13].



13. FRENCH HEM.

Hooks and Eyes. These are firmer if sewn on with loop stitch, the tails or bills of the hooks one-eighth of an inch inside the edge of bodice, whilst the heads of the eyes should be one-eighth of an inch beyond the edge of bodice [14].



14. SEWING ON HOOKS AND EYES.

Loops and Eyelet Holes. These are used for hook fastenings, when the material or making is not suited to eyes or bars, as in transparent or thin materials, fancy yokes and cuffs, unlined blouses, etc. For loops, first make a bar of two or three threads of twist, according to the size of the loop, and the material it is worked on, as thin or transparent goods require smaller loops than, for instance, a woollen material, and of course much depends on the purposes for which they are required. Make the bar about a quarter of an inch in length, then work the threads over with loop-stitch, working from left to right, and passing the head or eye of the needle under the bar of threads, so as not to catch in the material. The stitches must necessarily be quite closely together [15].

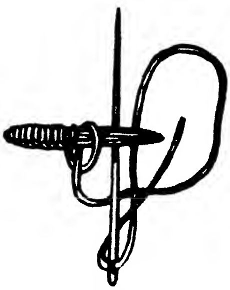
Eyelet holes are used in some cases instead of loops or eyes. In these the hole is made with a stiletto, and worked round closely in over-casting stitch, inserting the needle about one-eighth of an inch in the material when doing so. The hole should afterwards be rounded by passing the point of the stiletto through from underneath, just enough to open it, and no more. If for lacing, loop instead of over-casting stitch, closely worked, is best [16].

Easing. This is a term much used in dressmaking, and one that is more frequently misunderstood than any other. It does *not* mean puckering or gathering, but just fulling the material so that the one part shall set quite easily on the other. Either holding the part to be eased over the hand when doing it, or placing this portion uppermost, or towards the worker, will give what is known as easing, in which no fulness should be discernible.

False Hem. This is a piece of double material the same width as the hem, stitched with this on the wrong side to form a wrap for fastenings of unlined bodices, etc., or anywhere where these are better invisible.

Piping or Cording. This is now used mostly for ornamental purposes, to finish off the edges of revers, cuffs, etc., and not, as some years ago, for putting in the sleeves, or edging the basques of bodices. For single piping, cut a strip of material exactly on the cross, about one inch wide, join all the seams evenly, press open, snipping the selvedge, or cutting off the edges

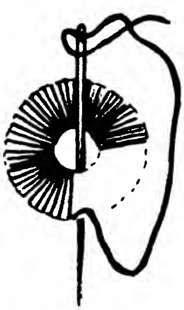
of these; place the piping cord in the centre of the crossway strip on the wrong side, fold over the other half of the bias strip, and tack or run along, quite close to the cord, pushing this up into the centre. For double piping, cut a crossway piece about two inches in width, fold over half an inch, place and run the cord in the fold, exactly as for single piping. Now fold the remainder of the width in half, place the cord in the centre of this, and with the thumb and fingers of both hands arrange it firmly in position above the first cord, being careful to keep the cord tight and not to let the crossway strip twist. Then tack closely to the cord. When sewing on piping, be careful not to stretch or pucker the edge, and when finishing off, cut the cord (not the material), so that it shall be just level with the end of whatever has been ornamented in this way [17].



15. LOOPS.

Button-holes. For some time past button and button-hole fastenings have not been so much in evidence as the other, and more invisible, fastenings now in vogue. How to work a button-hole is, however, indispensable knowledge to a dressmaker, or to anyone aspiring to sartorial attainments. For the preparation of the front for the button-holes, see Part III., where the directions are given in bodice-making.

In making button-holes, it is of great importance that they should be cut straight; a flat rule with a straight edge can be employed in making the requisite line. If there is a series, see that they are of equal distance apart, and all the same size. A tape measure can be used for this. The first button-hole should be worked on the waist line. The edge of the button-hole should be cut one-sixteenth of an inch away from the front fitting line, not from the edge of the bodice; the hole must be cut a quarter of an inch longer than the diameter of the button. The distance between the button holes is from three-quarters to one inch, according to the size of the button. Fancy buttons are placed half an inch apart. When the button-hole is marked, before cutting, stitch round the mark to prevent the material and lining slipping apart. Then cut with button-hole scissors and work one at a time. In the diagram the last stitch is separated from the others for the sake of clearness.



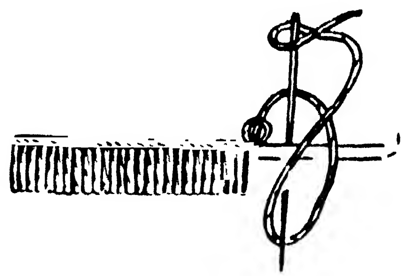
16. EYKLET HOLES.

Working the Button-hole. Take a needleful of silk twist, No. 12 for cloth, 14 for material (this is medium twist) about three-quarters to one yard long, with a No. 5-6 needle. Use the twist double to bar the edge before

17 PIPING

working to make this firm. Insert the needle between the material and facing to hide the knot, bring it up about one-eighth of an inch from the edge of the left side of the hole, carry the twist straight along, insert the needle in the material, and bring it up again at the same place, making long stitches, or a bar, round the edge, and so on, back to where you commenced, keeping the bar slightly tight, and taking care that it lies along the hole at equal distance from the edge.

The button-hole is worked with single twist. Insert the needle when working as closely as possible to the bar, but before pulling it out,



18 BUTTON-HOLING.

twist the thread over the point of the needle to the right of worker, to form the purl, or ridge at the edge of the hole. The needle should then be pulled out, the hand being drawn upward and forward, setting the loop, or purl, exactly on the edge of the hole. When the eye is reached, the stitches should be rather closer, and the purl well thrown up at that part. Repeat the process, stitch by stitch, until the hole is finished. Now bar the bottom or end of the hole by passing the needle across the end three or four times. To work the bar, the front of the bodice is held with the eye of the button-hole towards the worker. Three or four loop stitches are now put over the bar to make the ends neat and firm. Having completed the bar, the needle is passed through to the wrong side, and the thread fastened off with two or three invisible stitches. When finished, tack or sew the edges together in the middle and press on the wrong side [18].

How to Sew on Buttons without Shanks. This is a very important detail, and as the "mere man" is very fond of reproaching

woman for her ignorance of the art of sewing on buttons, it behoves her to pay attention to this paragraph. Buttons should be sewn on loosely with strong thread When doing so, place the knot of the thread outside the material, under the button, or between the outside and the facing; put the needle through the hole, and bring it down through the opposite hole, but before pulling the thread tight, place a bodkin through the loop, and continue to work two or thr e more strands over the bodkin Before removing the bodkin, bring up the needle to the sides of the button tightly, and quickly twist the thread round the button between it and the material to form a thread shank Fasten off with two or three back stitches under the button The loose sewing on and the winding round the threads really increase the durability of the work, besides allowing for the thickness of the material Buttons with shanks should also be sewn on loosely with strong cotton

Hook and Bar Fastenings. The preparation is the same as for button holes, as described fully in the making of the bodice Tack down turning of front a quarter of an inch from the fitting line, leaving three quarters of an inch for the turn-down This should be tacked and pressed. Then serge the raw edge to the lining, and tack with white cotton on the right side of the bodice This is a guide for putting on the hooks, which are sewn on with the edge of the bill just touching the white cotton on the turn-down The bars are sewn on the fitting line of the left side of bodice, the eyes of the bars being placed towards the edge of the bodice, the long edge of the bar on the fitting line The right side of the bodice is faced as for hooks, the left side the same as for buttons.

French Seam. Also called mantua-maker's seam This is much neater than over-casting for thin, unlined materials, as when these are of a very "frayey" character the latter is not enough to keep the raw edges from ravelling Place the two edges to be seamed together, and run along, on the right side, about one eighth of an inch from the edge. If the material be slightly on the cross, be careful that the thread is neither too slack nor too tight. Cut the ravelled ends of the joined portions, to prevent them sticking out when the seam is done, turn over, and crease to keep the stitching near the top, and either run or machine along quite close to the edges which have just been turned over. Be very careful to keep the stitches close up to the turned in edges, or there will be a fold on each side of this, and the seam will not be straight. Also be careful not to pucker the material in the second running, for which reason the beginner had better tack it along before doing so.

Tucking. This plays a very varied and also ornamental part in dressmaking. A tuck may be defined as a fold of material, either run or machined at certain distances from the edge. Tucks may vary from one sixteenth and one eighth of an inch (when they are generally designated pin-tucks) to one inch and more in width, and are employed in a variety of ways for ornamentation on bodice, sleeves and skirt. They are usually worked on the straight of the material. When done by hand, fold over and crease the material for the first tuck, take a strip of card, cut a notch in it the width the tuck is to be, run along, keeping the point of the needle always even with the notch. If preferred, it can be tacked before running For the next tuck, measure the space to be between the first and second, and make another notch ; this will give the place for the crease of the second tuck, which must be the same as the first The other tucks must be made in like manner. With regard to the spacing, see UNDERCLOTHING Most of the tucking is now worked, however, by machine—with or without the aid of "tuckers"—and of late is generally done by pleating the material to the depth required for the tuck and then stitching through the three thicknesses on the right side, once, twice, or even more, as desired This way keeps the tuck quite flat, and brings the stitching more in evidence, which, if a contrasting colour be employed, makes a pretty finish.

The Use of the Sewing-Machine. It will be well for the amateur to practise a little on the machine, either with hand or treadle, to see that she can work this smoothly and keep the seams even with the tack marks, as a slight deviation in a seam may make a considerable difference to the set, and, of course, will make it uneven

When about to machine-stitch the seams, thread the needle with the cotton required, which will depend on the material to be stitched. For serges, soft woollen goods, cashmere, etc., No. 40 cotton for the shuttle, and No. 50 for the needle For very thick woollen materials, No. 40 should be used for both upper and under cottons, whilst for very thick, hard materials, or cloth, No. 30 cotton should be used for both shuttle and needle.

Fine materials, as muslin, silk, etc., will require No. 50 for the shuttle and No. 60 for the needle. If coloured cotton be used for coloured goods, see that this is a shade darker than the material, as it always works in somewhat lighter.

See that the tension is right before starting ; if too tight the thread will snap

To machine-stitch the seams of the bodice, place the seam underneath the needle, let down the foot, or presser, and start the machine, guiding the work with the hand to keep it straight and steady. When the seam is done, loosen the top cotton a little to prevent it dragging, and so breaking the needle, lift up the presser, remove the work from the machine, leaving a long end of cotton on both the work and the machine ; thread a needle with the end of that remaining on the work, and finish off with a few stitches. There are many makes of machines on the market, but Singer's and Wheeler & Wilson's are too well known to need recommendation. Of the latter make, No. 9 is the best for general dressmaking purposes.

A. TAYLOR ALLEN, Member of Incorporated Association of Municipal and County Engineers

CHARLES ORMSBY BURGE, Past President of Royal Society, New South Wales; Engineer-in-Charge of Hawkesbury Bridge

CIVIL ENGINEERING AS A PROFESSION

By Professor Henry Robinson

THE profession of a Civil Engineer includes all branches of engineering practice, and involves sufficient knowledge of them to enable the engineer to bring to bear on any work he has to carry out a skilful appreciation of the best known methods which may be applied. To successfully comply with these conditions requires a mind capable of acquiring and utilising a great variety of technical experience, and the preparation for such a career involves the assimilation of theoretical and practical knowledge over a wide range of subjects, and the avoidance of specialising at too early a stage.

A Civil Engineer's Training. The training of a civil engineer may be compared to that required for a medical practitioner, who obtains his qualifying degree after a definite course of study and practice in all that pertains to medicine and surgery, although in his subsequent career he may devote himself to a special subject: so civil engineers are often identified with some particular branch of the profession.

Although the great English engineers of the last century attained their eminence without such training, the conditions which engineers of the future have now to meet are widely different from theirs. In this country the training-schools have come into existence largely through private enterprise, and not through national aid. In Germany, America, Switzerland, and elsewhere the State has founded training-schools with the best equipments, and the most skilled teachers, the whole matter being dealt with as one of national importance. The result is that English experts meet in competition better-trained men from outside. This has been recognised, and is being remedied to some extent. Too much emphasis cannot be laid on the necessity for adopting a well considered system of training and enforcing it. At the present time the arrangement of the subjects that are dealt with in many of our technical schools is largely governed by the predilections of one or more of the teaching staff. If a youth has a definite career marked out for him, so that he knows that he will be associated with mechanical, electrical, mining, shipbuilding, or other branches of work, his training admits of variation and limitation to meet this, but the preparation for the profession of civil engineering requires a broader basis to admit of future developments in any required direction. Much more could be done during the school period to prepare for this. The preliminary education, which precedes what may be termed the academic, or college, training, admits of adaptation to meet the requirements of modern life, and the heads of many of our great schools are recognising this. If a youth remains at school until he is seventeen, he should have the foundations laid for some of his subsequent work. A part of his school-time could be devoted to drawing, physics, chemistry, workshop practice, mineralogy, and such subjects as would be useful in a general education even if the youth is not destined to follow engineering.

Function of the Engineer. In settling the course of training at the academic period, as distinguished from the preliminary, or school, period, the aim should be to enable the student to obtain a clear grasp of what has been arrived at theoretically and practically in the past, whilst pointing out also the direction to take for future developments. An intelligent youth is more likely to apply himself to mastering information if he recognises that the knowledge he is assimilating is capable of utilisation.

The function of the engineer has been defined as "directing the great sources of power in nature for the use and convenience of man." To embrace all this in the term Civil Engineering involves a carefully considered course of preparation both in theory and practice. How can this be best accomplished? A technical college should be arranged so as to be capable of giving the preliminary training, both theoretical and practical, and the training should be on as broad a basis as possible to enable the student to adapt himself to the varying and unknown conditions of his future career. To specialise his instruction would be likely to confine his sphere of action within such narrow limits that, unless he can find the exact opening in which that special knowledge is required, his time would have been practically wasted.

Is Workshop Practice Necessary? It is held by many that the practical information to make a civil engineer can only be obtained by passing some time in workshops either before or during the college training. This view is based on the assumption that it is essential for a civil engineer to know about workshop practice, and is the survival of old tradition applying to the time when engineering was practically limited to mechanical work. Some who advocate a year or more in workshops before the youth enters upon what is termed the academic course contend that by following this plan he can ascertain whether the engineering profession is one which he desires to follow. If the civil engineering profession could be judged by such a course, the youth would probably wonder whether his time could not be better employed than in devoting valuable time to learning in the shops where he is at work all the details of manufacture of some particular machine or apparatus that is being made there. Sir William Ramsay quite lately expressed a similar opinion. "In my opinion," said he, "far too much stress is laid nowadays on what is called practical work. To take my own subject, it is possible to have quite an intelligent idea of chemistry without ever having handled a test tube or touched a balance. Lectures on chemistry may be well illustrated experimentally, and the necessary theories demonstrated by the lecturer. Of course, that will never make a chemist, but we are not talking of making chemists, we are discussing the best way of giving education, and I maintain that to spend several hours a day in practical work is, if not waste of time, at least a work of supererogation."

An illustration of this may be given in the case of a civil engineer, now at the head of the profession, who started life under the conditions laid down—namely, of a year or more in workshops before entering upon the academic period. After passing a few months in one workshop, doing the same work day after day, he succeeded by strong influence in getting a change to another shop, where he had a similar experience. He endeavoured to arrive at an understanding of some of the commercial conditions of manufacture which he was told would be useful, but failed to induce any of those in authority to afford him the information. He finally curtailed his workshop period, and entered a technical college, afterwards becoming a pupil of a Civil Engineer.

Value of Observation. If workshop practice is necessary in order to afford experience in processes and machinery, why should it not be of greater importance that a youth who is intended for the Civil Engineering profession should pass a period of time during his training on railways, waterworks, docks, harbours, road-making, sewerage, sanitary and other works of the kind? It is important to know the properties and uses of materials employed in the execution of works, whether in civil, mechanical, sanitary, or electrical engineering; but a youth will not learn this in a workshop, and he may pass a valuable year of his life in a shop where only one or two special machines, or apparatus of some special kind, are being made. If all training colleges had good workshops attached to them—as is the case in some—a more varied and useful course could be followed in them than is possible in a factory where the youth has to spend his time in a particular shop for a period determined, not by his own need as a learner, but by the work that is going on at the time.

School Work. If the education of a Civil Engineer could be standardised, it would be possible for a properly-established and equipped college to enable a youth to acquire the theoretical and practical instruction which will fit him to take part in actual practice. There are several technical schools which are shaping their course with this aim in view, and there is urgent need of the plan being carried out on a scale commensurate with the importance of the subject from a national standpoint. The necessity for adopting better methods of training than now exist in this country is recognised, and there is a consensus of opinion that other countries are ahead of England in this matter, but the solution of the problem has not received that impartial consideration which it requires. The preliminary school work should be arranged so as to prepare a boy for the advanced theoretical and practical course of a college, well equipped with drawing offices, laboratories, workshops, lecture rooms, etc., to enable the training to be thorough and wide enough to include all that can be taught in the school period and before the youth enters an engineering office as a pupil assistant.

As this Course is intended for the student, it may be useful here to indicate briefly the nature of the works which are embraced in

the practice of a Civil Engineer, in which there will be, for all time, openings for well-trained men in this country and abroad.

Railways. Selection of the route for railways, light railways, tramways. Systems of traction; studying the requirements of the districts to be served by them; surveying and levelling the country to determine the best route for the lines; ascertaining the geological and physical geographical conditions of the country; noting the streams or rivers to be crossed, and the best way to bridge them.

To select the best route involves a knowledge of the use of instruments in the field, and of what route will best serve the commercial conditions of the case, with the best gradients, and the least cost involved in banks, cuttings, tunnels, viaducts, bridges.

Arranging the route by contouring the country, so that the material removed from cuttings balances, as far as possible, that which is required for the embankments. Designing the works to prevent slips in the banks and cuttings. This requires close observation of the strata in which the work is carried out, so that no springs or surface water can collect and produce either a slip or a settlement. Subways. Stations. The maintenance of the railway, its works, permanent way, etc. A resident engineer must be capable of dealing with defects or failures which arise.

Water Supply. Inspecting the district to determine the sources of supply available. Ascertaining the rainfall on the watershed to be utilised and gauging the river from which water is to be taken. The requirements of the community to be served. Constant or intermittent supply. Pumping surface or underground water. Well sinking. Storing water in impounding reservoirs. Selection of site for such reservoirs. Designing and constructing earthwork, masonry, or concrete dams. Calculating stresses. Service reservoirs. Quality of waters. Analyses. Hard and soft water. Softening hard water. Purifying polluted water by filtration or sterilization. Distribution in towns. Flow in pipes and culverts.

Sewerage and Sewage Disposal. Sewering a town on the combined or separate system. Calculating gradients and sizes of sewers. Construction of sewers. Materials to be used and methods of laying sewers according to the sub-soil. Manholes. Lamp-holes. Ventilation and flushing. Admission of trade wastes to sewers. Methods of disposal of sewage. Discharging into the sea, rivers, or estuaries. River pollution. Tidal and other observations necessary. Disposal of sewage on land. Irrigation. Filtration. Suitable and unsuitable soils for these purposes. Chemical precipitation. Sewage sludge. Bacterial treatment of sewage (Aerobic and anaerobic). Management of outfalls.

Surveying. Surveying and levelling. Use of instruments in the field. The Theodolite, Level, Sextant, Box Sextant, Prismatic Compass, Circumferentor, Transit, and Tacheometer. Determining the meridian at a given place. Traverse surveying. Plotting surveys and sections. Drawing office practice. Underground surveying for tunnelling, mining, etc. Hydraulic surveying. Float observations to determine currents. Soundings at sea and in rivers to prepare charts. Gauging rivers and streams. Triangulation. Measurement of base lines. Curvature and refraction. Preliminary surveys. Plane table. Station pointer. *Contouring.* Setting out curves.

Hydraulic Engineering. Docks. Harbours. Sea walls. Groynes. River improvement. Training walls. Reclamation of land. Weirs. Fascines. Dredging. Foreshore protection. Erosion of coasts. Piling. Wharves. Foundations. Underpinning.

Roads. Main roads in town and country. Laying out the best routes. Construction. Foundations. Draining. Wood-paving. Asphalte. Macadam. Stone setts.

Power. Conservation and distribution of power by steam, gas, water, compressed air, and electricity.

Materials and Construction. Cements. Concrete. Proportions and materials for concrete for various purposes. Brickwork. Foundations for buildings and machines. Iron and steel work. Framing. Bridges of wrought iron, steel, or timber. Calculating stresses. Designing structures in iron, steel, concrete, timber, brickwork, etc. Arches. Utilising combinations of concrete with steel and iron.

Machinery. Steam engines. Boilers. Gas works. Gas-producer installation. Pumping engines. Turbines. Waterwheels. Internal combustion engines. Hydraulic engines. Vibrations.

As the ultimate aim of all young men who propose to become Civil Engineers is to become associated with the Institution of Civil Engineers, the rules laid down by that body should be considered as bearing on the course of education that has to be followed by a student. The grades of membership are divided into three, namely, Members, Associate Members, and Students, and it is with the last two that we are now concerned. The Institution holds special examinations for candidates for admission as Associate Members and Students. Exemption is granted in the case of students entering most engineering colleges if the matriculation examination is passed. Exemption is also granted to intending Associate Members if they have passed with Honours the Examinations held by a great many colleges at the end of their courses. A tabulated list of the subjects that the Council of the Institution of Civil Engineers require intending candidates to pass before admission is given at the end of this article. It includes one of the examinations that the Council will accept in lieu of entering for their own, and is one of many other well-recognised degrees that will also suffice.

Examinations. With regard to his admission as a student the Council stipulates that:

1. Where the usual routine of pupilage is being, or has been, served under a corporate member, the pupil may be proposed

as a student at any time after the commencement of such pupilage.

2. Where a course of training at any public institution approved by the council is being, or has been, pursued under a teacher who is a corporate member, the latter may propose a pupil for admission as a student after he has begun a second year of training at such institution.

3. A corporate member may propose for studentship an assistant who has been in his office or works for a period of not less than 3 years.

The Council holds that the special education of a Civil Engineer should in all cases cover a period of two or three years—according to whether the pupil has gone through a college course or not and that this period should in all cases include a course of practical training in or upon engineering works.

SURVEYING

The term surveyor, when associated with the subject of Civil Engineering, differs from the term as understood by the "Surveyors' Institution," the official definition of surveying by that body being "the art of determining the value of all descriptions of landed and house property, and of the various interests therein; the practice of managing and developing estates, and the science of admeasuring and delineating the physical features of the earth, and of measuring and estimating artificers' work."

Practical Knowledge of Instruments. It is intended in this introductory article, and in the subsequent course, to deal with all branches of the surveying profession with the exception of quantity surveying and valuing, which are dealt with elsewhere. The scope of this course may be broadly summarised as embracing Railway, Marine (or hydraulic), Land, and Mining (or underground) Surveying.

It is essential for a young civil engineer to acquire a practical knowledge of the use of the various instruments, and of the several field operations connected with surveying, levelling, etc. Whatever branch of the profession he follows, he will be called upon to do work involving this knowledge, whether the work be on the surface of, or under, the earth, or afloat. He should be well grounded in practical (or applied) mathematics, which will greatly assist him in the solution of the problems that arise in extended trigonometrical surveys, involving the determination of distances, heights, etc., without actual measurement. In this work logarithmic tables are a great help.

In simple surveying operations the Gunter's chain (of 66 ft. or 100 links) is usually employed in this country. Sometimes a 100-feet chain is used. Survey lines are tied together by means of chain angles—as distinguished from instrumental angles. The positions of the various points adjoining the chain line that require to be taken and recorded in the field book, and to be plotted on paper subsequently, are ascertained by measurements made with an "offset staff," 10 links long, taken at right angles to the chain line. Setting out these lines, by ranging them truly, is essential. The distance that the offsets can be taken accurately is limited, as the direction of the several offset lengths at right angles to the chain line is determined by the eye. The arrangement of the links to make a chain survey of this description requires skill, in order to complete the survey, and to include every object, with the minimum number of chain lines. If the ground is hilly "double ranging" must be resorted to.

Levelling. When it is necessary to take offsets of some distance from the chain line various forms of instruments can be employed, such as the cross, box sextant, and optical square, which enable a right angle to be set out with accuracy. In the event of the survey being carried out by angular measurements, the theodolite is the usual instrument employed. For smaller works, and for filling in details, the prismatic compass is used.

In the office it is frequently necessary to make reductions of plans that have already been plotted to a large scale. These reductions can be done by the method of "squares," or more rapidly with the use of the eidograph and pantagraph. It is also very often required to take out the areas of various portions of a survey, and the instrument generally used for this purpose is the planimeter. Setting out curves with the chain alone, or with the chain and theodolite, will be described in detail in the course. When it becomes necessary to determine the relative positions with regard to vertical height between points on a Survey, the level is used. In order to be able to plot these points (to make a section of the ground), it is usual to chain between them, and take readings with the level on a level staff at the several chain points, the distance and readings of heights being entered in a level book to enable them to be plotted to scale on paper. The level staff is 14 ft. long, graduated to feet and tenths of a foot. In the event of its being necessary to ascertain the level of the ground on either side of these lines, it is necessary to take what is known as cross sections. These are taken at points where there is any considerable variation in level of the ground there, and at right angles to, and on each side of, the chain line. In this country the Ordnance Department have established Bench Marks (called B.M's), and their values are recorded, the figures representing the height of the points above mean tide at Liverpool, which is the standard datum.

Ordnance Survey. Starting from one of these known points, the levels of any other points may therefore be established with regard to this datum. By laying down a datum horizontal line on the paper, representing any convenient height above the standard datum, and by drawing lines perpendicular to it at the various chain points, the relative levels of the various points on the section may be plotted to scale, and the line joining these points is the actual surface of the ground.

The Ordnance Survey greatly facilitates surveying work, and often the only field-work that is required consists in the filling in of details or alterations of lines, etc., that have been carried out since the Ordnance Survey was last corrected. In cases, however, where large surveys have to be carried out the theodolite is employed for triangulation by taking the angles between long lines, or by "traversing," which means taking the magnetic "bearings" of the lines by the needle of the theodolite or prismatic compass.

The beginning of all large surveys is by measuring a base line with a chain most accurately, the several chain lengths being taken with the chain perfectly horizontal. A better way is to use bars for the measurement of these lines, and these must be compared at times with standard bars, in order to check their accuracy. From this base line will be constructed a system of triangulation to enclose all objects necessary to complete the survey. In mountainous districts the sides of the triangle may be very considerable, as the theodolite readings can be taken to stations many miles apart. All these base lines have to be reduced to sea-level, so that it is necessary to ascertain their relative levels.

Stations for Small Surveys. The positions of stations for small surveys can be fixed by means of the theodolite and chain, and their vertical differences of height by means of the level. For extended surveys they have to be determined by the tacheometer and omnimeter. The aneroid barometer can be employed for rapidly ascertaining differences in height, care being taken to note variations of barometric pressure. The ordinary barometer can also be used by applying a formula to convert inches, or fractions of an inch, into feet. The hypsometer is another instrument used to ascertain differences in height by recording the boiling-point of water at the respective stations. In recent years the tacheometer has come into prominence, and by means of this instrument the vertical and horizontal distances in rough countries can be determined with great accuracy and rapidity.

A method of carrying out surveys that was largely employed in America, and is now utilised generally, is that of the Plane Table, by means of which the map is sketched in on the ground as the survey proceeds. For the mapping of new countries, and the surveying of routes for railways, the surveyor must be able to locate his position by finding the latitude and longitude of the place. It will therefore be necessary for him to have a certain knowledge of elementary astronomy. A knowledge of mensuration is also essential in order to be able to compute areas and take out quantities.

Mining and Marine Surveying. The chief differences in mining and land surveying are in respect of that portion which has to be accomplished below the earth's surface, in order to locate the direction of the various headings and tunnels. The "Circumferenter" or "Miner's Dial," is largely used in this work, and the directions of the various headings are ascertained by taking the "magnetic bearings" of the lines with the Miner's Dial, and by chaining their lengths, the lines being afterwards plotted in the ordinary way. It will be explained how the "variation" of the magnetic needle has to be taken into account to prevent the mistakes which have often happened in laying down new observations on an old survey without making due calculation for variation.

Hydrographical, or marine, surveying has for its object the preparation of plans and charts to indicate the positions of shoals and bars, either for navigating purposes or for civil engineering operations. The surveying of foreshores and rivers by the Admiralty is recorded on charts, the position of subaqueous ground being indicated in fathoms (or six feet units). The civil engineer has, however, frequently to supplement the official charts by detailed observations in some locality for special purposes in connection with contemplated works. He has to take float observations to determine currents and the direction of tides for many purposes in his practice. The Sextant and Station Pointer are used when the observer is afloat, and the Theodolite when he is on shore taking readings to stations afloat, either fixed buoys, drifting floats, or any assistant in a boat taking soundings by signal at the instant the position of the boat is fixed by the observations made on shore. This kind of surveying is constantly called into requisition in connection with harbour and dock works, foreshore protection and the erosion (or removal of material) along coasts. It is essential to be familiar with it where sewage outfalls discharge into the sea or tidal estuaries, so that full knowledge is obtained as to what will become of the sewage before public money is spent in so disposing of it.

Railway Surveying. This branch of survey work resolves itself into two main features, that of the survey for the preliminary route and the final setting out of the work. The main features which govern the selection of the route are the grades and the curves, and have to be adapted to the general outline of the locality through which the line has to pass. In selecting a route, the surveyor must endeavour to arrange so that the excavation and embankments as nearly as possible equalise one another, to avoid having to "run to spoil" surplus excavation. The curves are usually set out with the theodolite and chain or by the chain alone. Many instruments have been invented for setting out curves, especially in flat country. Cross-sections have to be taken all along the centre line, so that the quantity of embankment or cutting can be calculated. Where the line is in tunnel it is usual to set the direction out on the surface of the ground and to sink shafts on the line at various points. The position of the station at the surface is then transferred to the bottom of the shaft, by means of a theodolite on the surface, and then produced underground, the level of the line at each shaft being accurately calculated and plumbed.

To be continued

SCHEDULE OF EXAMINATIONS FOR CIVIL ENGINEERS

(For Qualifications for Candidature, see Text)

Examining Body, Grades, Time, and Place of Examinations.	Subjects of Examinations — Obligatory.	Subjects of Examinations — Alternative or Optional.	Fees and Age Limits.
INSTITUTION OF CIVIL ENGINEERS. Students. London, Feb. and Oct. or at Manchester, Glasgow, Newcastle-on-Tyne in Feb.	**English.** A general Paper comprising questions in Geography, History and Literature. **Mathematics.** Arithmetic, Algebra. Geometry (Euclid I.-IV.). Trigonometry (up to and including the solution of triangles).	Two subjects, to be selected by the Candidate from the following ten: a language is not compulsory, but in any case not more than one language may be taken. **Latin, Greek, French, German, Italian, Spanish.** **Elementary Mechanics** of solids and fluids. **Elementary Physics,** including heat, light, electricity and magnetism. **Elementary Chemistry,** including the principal properties of matter, the laws of chemical affinity, atomic weights, valency, and the chemistry of the principal inorganic elements. **Geometrical and Freehand Drawing,** including projective and descriptive geometry and perspective.	£1 1 0 18–25
Associate Member. London February and October.	**Part I.—General Knowledge.** Candidates are required to prove their knowledge of the English language and their attainments in general knowledge by writing an essay of about 1,000 words upon one of certain set subjects. Persons who are, or who have been, Students of the Institution, or who produce such qualifications as would, under the existing Regulations, exempt from the examination applying to admission of Students are not required to pass Part I. of this Examination. **Part II.—Scientific Knowledge.** Applied Mechanics, Strength and Elasticity of Materials.	**Part II.—Scientific Knowledge.** Theory of Structures or Theory of Electricity and Magnetism. Two of the following nine subjects—not more than one from any group. **Group I.** Geodesy. Theory of Heat Engines. Metallurgy. **Group II.** Hydraulics. Theory of Machines. Thermo- and Electro-Chemistry. **Group III.** Geology and Mineralogy. Stability and Resistance of Ships. Applications of Electricity. **Mathematics.** The standard required for Part II. of the examination is that of the mathematical portion of the Examination for Admission of Students, though questions may be set in higher Mathematics.	£2 2 0 21 and upwards

UNIVERSITY QUALIFICATIONS WHICH SECURE EXEMPTION FROM THE ABOVE EXAMINATIONS

UNIVERSITY OF LONDON. B.Sc. (Engineering).

CAMBRIDGE. B.A. (Mechanical Science Tripos).

ST. ANDREWS. B.Sc. (Engineering).

GLASGOW. B.Sc. (Engineering).

EDINBURGH. B.Sc. (Engineering).

VICTORIA UNIVERSITY OF MANCHESTER. B.Sc. (with honours in Engineering).

LIVERPOOL. B.Eng., provided the degree be obtained by passing the Examinations of the University.

LEEDS. B.Sc. (with honours in Engineering).

BIRMINGHAM. B.Sc. (Engineering), provided the Engineering Matriculation Examination be passed on entering upon the course of study.

DUBLIN. B.A.I.

ROYAL UNIVERSITY OF IRELAND. B.E. and M.E.

UNIVERSITY OF WALES. B.Sc. (Engineering); provided Mathematics be passed at Final Examination for the degree.

MCGILL UNIVERSITY, MONTREAL. B.Sc. (in the Department of "Civil," "Mechanical," "Electrical," or "Mining Engineering) provided that Geography and either Chemistry or Physics be passed at the Matriculation Examination.

SCHEDULE OF SURVEYORS' INSTITUTION EXAMINATIONS

Preliminary. London, Dublin, Manchester, Glasgow. January.	Elements of Algebra, Euclid (first three books), English History, Composition and Writing from Dictation. One of three languages: Latin, French or German.	None.	£1 1 0 18–21
*Intermediate For Professional Associateship. London, Glasgow, and Dublin. March.	*Farm Buildings, Land Drainage, Geology and Soils, Chemistry, Bookkeeping, Law of Landlord and Tenant, Mensuration, Law of Fixtures, Dilapidations, Easements, and Riparian Rights, Application and Use of Valuation Tables, Copyholds, Drainage and Sanitation, Surveying, Levelling, and Elements of Trigonometry, Bills of Quantities, Constructive and Working Drawings, Composition and Properties of Stones and Cements.	None.	£3 3 0 (over 21)
*Final for Fellowship. London, Glasgow, and Dublin. March.	*Botany, Agricultural Chemistry, Valuations and Law, Forestry, Timber Valuing and Measuring, Local Taxation, Valuation, Law of Arbitration, Enfranchisement of Copyholds, Acts for Compulsory Purchase of Property, Law of Vendors and Purchasers, Quantities, Constructive and Working Drawings, Drainage and Sanitation, Iron and Timber Roofs, Specifications of Building, Report.	London Building Acts or Public Health Acts. Two of the following—Algebra, Animal Physiology, Development of Building Estates, Hydrostatics, Principles of Parochial Assessment, Road Making, Mechanics (Law of Forces).	£3 3 0 (over 22)
*Direct Fellowship. London, Glasgow, and Dublin. March.	*Same as Intermediate, except Bookkeeping and Surveying, with these additional in their respective subdivisions: Enfranchisement of Copyholds, Acts for Compulsory Purchase of Property, Development of Building Estates, Specifications of Building, Iron and Timber Roofs, Report.	London Building Acts or Public Health and Local Government Acts.	£3 3 0 (over 30, & must have practised on own account more than 5 years)

* Divided into three Sub-Divisions.—I. Chiefly Land Agency; II. Chiefly Valuations; III. Chiefly Building or chiefly Quantities.

1 *

THE CHOICE OF A PROFESSION

THREE considerations should guide the choosing of a career—the taste and temperament of the individual, the cost of preparation and instruction, and the probable rewards. The first part of the SELF-EDUCATOR contains a table of shopkeeping careers; the details which follow will guide young people and their parents in the choice of a profession.

Accountants. The candidate must pass a preliminary examination or show qualification entitling him to exemption, and serve five years indentured apprenticeship with a chartered accountant, who usually exacts a premium of from 100 to 500 guineas, part or all of which may be returned in salary. University graduates serve only three years in England, four years in Scotland. An intermediate and final examination must be passed. Most chartered accountants in business make handsome incomes, often anywhere between £1,000 and £20,000, but qualified employees are not usually paid in proportion to the fees charged for their services. There are several other bodies of public accountants with different membership qualifications, but without the prestige of the chartered accountant.

Architects and Surveyors. A course of two years at an Architectural School in London or the provinces – average fees £40 a year – is probably the best preliminary training, but a youth may enter the profession as articled pupil, improver, or assistant. A pupil is generally articled for three or four years, or if he has had preliminary training, for two years; usual fee 100 guineas, although 300 guineas is sometimes required. Preliminary examination of Royal Institute of British Architects is almost essential before apprenticeship. Three examinations are required before the title of Associate R.I.B.A. is obtained. Fees for examination, £9 9s. Improvers' salaries, about £50; junior assistants and draughtsmen, 30s. to £2 10s. per week; managing assistants, £3 3s to £5 5s. An architect's principal remuneration is 5 per cent on the value of works erected, or 10 per cent if buildings are small. Special charges are made for valuation. The salary of the architect to large trading companies or local authorities is from £500 to £700 per annum; assistant surveyor employed by local authority, £200 to £300. Average salary of a surveyor ranges from £500 to £600. Some technical Civil Service competitions are open to men trained in architects' or surveyors' offices, with salaries ranging from £150 to £700.

Army. Private means essential in this profession, £70 to £80 minimum for the first few years, and £50 afterwards. This will cover expenses only and not permit extravagance. Boy should be at a public school where pupils are prepared for Army, or may be sent to an Army coach. For the Infantry and Cavalry, he usually passes through Sandhurst (limit of age, 19, with two examinations). For Engineers or Artillery the cadet is trained at Woolwich (age for admission, 16 to 18). He may go through the Militia for any branch of the service. The regiment chosen should depend on the fortune at command. The Household Troops are the most expensive, then the Cavalry and the Infantry. The Indian Staff Corps officer receives quite three times the pay of his brother officer in England, and can live comfortably on his salary. The West India Regiment is a good one where economy is necessary.

Auctioneers. Usual indentured apprenticeship is three years, premium up to £100. Small salary, beginning at 5s. weekly, during apprenticeship. Assistant frequently begins at 20s. a week, plus commission on business he introduces. The two principal classes of auctioneers are property auctioneers and agricultural auctioneers. The former demands the greater ability. The two are often combined. A ready wit, a pleasant manner, and intimate knowledge of his business are essentials to a successful auctioneer. The profession is one where the right man makes money rapidly. A modest start may be made on £200. An auctioneer's licence costs £10 annually, and full gold and silver plate license £5 15s.

Bankers. Bank clerks usually begin as apprentices after showing certain educational qualifications, and serve three or four years, receiving from £10 to £40 a year to begin. In large city banks, director's nomination is usually necessary. Some London banks take apprentices at £60 or even £80. The work of the bank clerk is becoming more and more systematised into mechanical routine. Promotion is usually by £5 or £10 a year, until the salary reaches from £250 to £300. Cashiers, accountants, and managers get more. Many banks forbid marriage unless upon an income of £150 to £200. The Bankers' Institute affords opportunity of studying banking law and practice. The chief recommendation of the profession is that, although the average remuneration is modest, positions are practically secure for life, and pensions follow retirement.

Chemists. Apprenticeship of three to four years with registered chemist and druggist, during or prior to which the preliminary examination should be passed. Some certificates exempt. Minor examination of Pharmaceutical Society (fee £10 10s.) gives the legal title "Chemist and Druggist"; a higher examination, the Major (fee £5 5s.), gives the title "Pharmaceutical Chemist," and exempts from juries. In Ireland the examinations of the Pharmaceutical Society of Ireland must be taken.

Analytic chemists graduate from universities, technical schools, and pharmacies. The most useful degree is Fellowship of Institute of Chemistry, almost essential for appointments as public analysts, who are highly paid. Independently, a man may make his mark in special analyses, such as oils, fats, drugs, etc., and become recognised expert. The B.Sc. (London) is valuable, fee £5, but Matriculation Examination

[illegible] the [illegible] must first be passed. Expense of setting up as analyst not heavy, say £300 to £500. [illegible] ability, good luck, or influential [illegible] necessary to get beyond the usual £200 or £300 annual income.

Church. Candidates for the Established Church must hold a University degree or have passed certain examinations during residence at one of the Theological Colleges. An increasing number of men are now ordained without university qualification. The total expense of a three years' course at a church college (including board, tuition, and college charges) is usually £100 to £160 per annum, but Keble College, Oxford, exacts only £81 a year. The expenses of a non-collegiate student are, of course, less. At Dublin and Durham the course is only two years. Many livings are worth less than £50 a year, and a large proportion are under £100. Junior curates earn from £80 to £140 a year, and senior curates up to £200. The average country living is worth £200 to £400. In the Army and Navy chaplaincies yield pensions on retirement.

In the Congregationalist Church the course of study is usually five years, and students contribute about £80 a year towards their maintenance during the course.

Students for the Wesleyan ministry are selected by the circuit quarterly meeting and confirmed by Synod. They attend three years at a theological institute, and are expected to pay £50 to £70 a year. For poor students the fees are remitted.

The training for the Baptist ministry usually lasts four years, and students are expected to pay for their support and training if they can afford it.

The Presbyterian ministry involves a training of three to five years. A University Arts degree is practically essential as a preliminary qualification. Each year of the theological course is divided into three terms, and the terminal charge of £15 per term covers residence, board and tuition. By winning scholarships a student may work his way through a theological college without personal outlay.

Dentistry. Three years must be passed in mechanical dentistry under a qualified practitioner, either in private practice or in a hospital. Premiums for apprenticeship in private practice range from 50 to 150 guineas. At the London dental hospitals and colleges the *composition fee* of £160 includes three years' mechanical pupilage and two years' hospital practice and lectures. Dental students pass same preliminary examination as medical students and must register as dental students. By making mechanical practice and study run concurrently the course of dentistry may be condensed into four years. The degree of Licentiate in Dental Surgery is granted by Examination Board of Royal College of Surgeons. The Scottish and Irish diplomas are cheaper and easier to obtain than the English degree. Various degrees are given by recognised dental hospitals and schools.

[illegible] A good [illegible] higher [illegible] machine, [illegible], and freehand drawing, should be [illegible] basis of an engineer's education. An engineering course at a university college lasts three years' and fees vary from £60 to £170. During the first two years of training the instruction is similar for whatever variety of engineer is in the making. The railway companies take apprentices usually for five years at a premium of from £16 to £25, and give small wages during the term. Many private firms demand premiums of £300 for articled pupils. The best course is to study for a year at a technical college near the works of a good engineering firm, afterwards becoming apprenticed and continuing study. The cost of this course is from £300 to £500, including premiums. The cost of training can often be reduced by scholarships. In the three main branches of engineering—civil, mechanical, and electrical—prospects are fairly good all over the world, and the expenses of technical training are much the same in each. The highest paid posts are in gold mining engineering, where salaries occasionally rise to £10,000 a year. The rank and file of the profession is usually recruited from "unpremiumed" apprentices who, during their five years of service, earn from 2*s* 6*d* to 10*s* a week. Hard study and application often bring the prizes of the profession within their grasp.

Insurance. Conditions and salaries at the beginning are much the same as in banks. The posts for senior clerks are not so numerous as in banking, and the maximum salary is not so high. There are however, many good positions, such as inspectorships and branch managerships, to which a clerk with a capacity for pushing outside business may aspire. Branch managers make from £300 to £1,000, or even more. A young man with mathematical ability may pass the examinations and become an actuary, which will enable him to rise more quickly in the life department.

Journalism. Journalism, if it offers great rewards to those who succeed in it, demands great mental vigilance and physical endurance. The prizes of journalism will go more and more in the future to those who begin at the bottom of the ladder. Shorthand, typewriting, a sound knowledge of history, literature, and grammar; a working knowledge of French, with German if possible; an intelligent appreciation of public affairs, with a special interest in, say, European or American politics; some practical knowledge of printing conditions; observation, concentration, lucidity in expression—all these are factors in the making of the journalist. The boy should begin, for preference, in the reading room of a newspaper office, then becoming a junior reporter, either by apprenticeship or without it. As an apprentice he may be paid from 5*s*. to 10*s*. a week on a provincial paper, where training is easier to get than in London. Reporters may earn from £2 to £5 a week or even more in the provinces, or from £3 to £8 in London. Every journalist should have some experience in sub-editing,

which [illegible] the same [illegible] as reporting. [illegible] as a career is [illegible] and only those who can face the varying fortunes cheerfully should enter upon it. It is likely to be more strenuous and [illegible] still, but the journalist with character, initiative, and a serious interest in his work will not be disappointed.

Law. The legal profession is much overcrowded. Years of waiting may be necessary before business comes, and the would-be barrister should have capital. There are four Inns of Court—Lincoln's Inn, Middle Temple, Inner Temple and Gray's Inn. Preliminary examination is necessary, but numerous university qualifications entitle to exemption. Students must "attend twelve terms," which means a minimum period of three years—*i.e.*, they must eat a specified number of dinners. The fees paid in Gray's Inn are the least expensive—on the student's admission, £39 13*s.* 6*d.*; and on his call to the bar, £89 2*s.* 4*d.* Additional charges are the dinners, coaching with a barrister—which is usual, but not compulsory—and the living expenses during the years of study. The law does not yield enormous incomes except to those at the top. The average legal income of qualified barristers is less than £50 a year.

The youth who would be a solicitor must pass a preliminary entrance examination—from which, however, certain university diplomas entitle to exemption. Apprenticeship is for five years, except for London University undergraduates, who serve four years, and graduates of London, Oxford, and Cambridge, who serve only three years. Usual premiums for apprenticeship £100 to £300, with stamp duty, £80. For intermediate and final examinations the fees are £3 and £5 respectively. An independent start as a solicitor should only be attempted if there is capital or a secure small income at command. An ordinary country solicitor should earn from £500 to £800 a year.

Medicine. Students must pass a preliminary examination, unless they hold University certificates exempting them. The minimum length of study is five years, and class, hospital, and examination fees reach £100 to £200. A student may, with economy and hard work, go through a medical course for £400 at some universities. Poor men should utilise the medical schools where bursaries are numerous. There are many congenial openings for the medical man. Medical officers on the chief ocean liners earn £120 to £150 a year; resident prison and asylum doctors, £200 to £500; and non-residents, £50 to £250, the latter being allowed private practice. Police surgeons are paid usually 5*s.* per man attended. Poor law medical officers receive £20 to £200. Medical officers of health average £400 to £500 for whole-time officers. Other posts yielding regular incomes are those of consulting medical officers to insurance companies and government departments, and medical inspectors of ships. Army surgeons begin at £200 per annum, and navy surgeons at £209. The largest incomes in private practice are earned by specialists.

[illegible] In Veterinary [illegible] Council or [illegible] Preliminary [illegible] of the [illegible] Institute of Scotland. Then, during four years' study, he must pass four professional examinations. Examination and registration fees reach £21. Fees at the Royal Veterinary College, London, aggregate £90, paid in four instalments. In the Royal (Dick) Veterinary College, Edinburgh, matriculation and class fees are only £58 16*s.* Veterinary surgery offers good prospects to young men fond of outdoor life and animals.

Musicians. Exceptional talent is necessary to reach eminence in the musical profession. The musician should begin early. Many of our prominent musicians were distinguished as children, and there can be no doubt that early training "tells" in music more than in most other professions. Private tuition ranges from 20*s.* for twelve lessons to any fee the teacher can command. The Royal Academy of Music in London charges five guineas entrance fee and 33 guineas annually, payable 11 guineas per term, but as there are many scholarships, clever pupils often complete their curriculum almost free of cost. At least one year must be passed in study. The Royal College of Music gives three years' instruction at 12 guineas per term. These colleges and several universities give degrees in music. The biggest school of music in the world is the Guildhall School in John Carpenter Street, London. The chief provincial schools are Royal Manchester College of Music, and Royal Irish Academy of Music (Dublin). In the Paris Conservatoire education is free, but entry is possible only by examination. Students at Leipzig Conservatoire study for three years, except where able to join the advanced classes at once. Expense, including board, lodging, and fees, is usually reckoned at £90 a year. Ordinary church organists earn from £20 to £100 a year, but usually have the right to teach upon the church instrument. Private engagements are profitable, evening "At Homes" yielding from 10*s.* 6*d.* to 2 guineas up to £60 or £100. Orchestral engagements yield from 45*s.* to 5 guineas per week. For other music, common rates are 25*s.* to 42*s.* for bandsmen, and 30*s.* to 50*s.* for principals.

Navy. Naval cadets must pass entrance examination (fee 10*s.*) between 13 and 14½ years of age, after having obtained nomination from First Lord of Admiralty. Examinations are held half-yearly—June and December—in London. Two years' service on the "Britannia," costing £100 a year inclusive, follow the passing of this examination, and there is an examination at the end of each term. Then the boy is a midshipman, and rises, if following the executive side, through the grades of sub-lieutenant, lieutenant, commander, captain, and perhaps to rear-admiral, vice-admiral, admiral, and Admiral of the Fleet. Other branches of the Service are the engineering, medical, paymasters, and Royal Marines. The naval officer may follow his profession without the private means necessary for an army officer.

Painting and Sculpture. The artistic temperament, the perception of the beautiful and the ability to express it, alone justify the adoption of art as a career. Both day and evening instruction is given at the art schools. The chief London school is the Royal College of Art, South Kensington, where fees range from 5*s.* to £5 per term, and under certain conditions students are admitted free. In South Kensington comfortable board and lodging may be had for £60 per annum. The Royal Academy schools are difficult to enter. Competition for studentship is keen, and more than moderate ability is required to secure admission. Instruction, limited to three years, is free. The age limit for painters is twenty-three and for sculptors and architects, twenty-five. Other art schools include the Polytechnic Institution, City of London College, and the Birkbeck, Camden, and Lambeth Schools of Art. In all of these day tuition costs a few guineas per term, and evening tuition a few shillings. At London University College, in Gower Street, fees are from 3 to 15 guineas for nine months; at Royal Female School of Art £1 to 13 guineas, and at Herkomer School of Art, Bushey, Herts, 18 guineas. There are numerous provincial schools of art, such as those in Liverpool, Manchester, Birmingham, Nottingham, Sheffield, and Glasgow. Study abroad is less costly than study in Great Britain. In Julien's Academy, in Paris, fees are from £1 to £2 per month, and the total cost of living and study in Paris need not exceed £7 or £8 per month, and may well be less. Students in Antwerp often get along on £1 per week. The chief fields for the artist are in painting, in black-and-white work for newspapers and magazines, and in teaching.

Sanitary Inspectors. The profession is best entered after passing the examination of the Sanitary Institute; fee, 4 guineas; expenses of coach usually 5 guineas. Whole time officers receive £100 to £250 a year, and occasionally more.

Stage. The stage is the most heart-breaking of professions. Preliminary training may begin in the elocution class of a local institution, with membership in an amateur dramatic society. Deportment, elocution, and dramatic action are taught at London School of Music and Royal College of Music. There are several dramatic academies in London, a course of lessons costing 4 to 12 guineas. Male "supers" are paid 1*s.* 6*d.* to 2*s.* 6*d.* a night, rising to 30*s.* a week. In London they are usually soldiers from the barracks or reservists. Ladies employed to "walk on" receive 20*s.* a week. In London, ladies of good social position are preferred. For a speaking part £2 to £3 a week is paid; for moderate talent, £3 to £5 a week; and for stars up to £60 a week. Those who rise higher are the very few exceptions.

In "musical" theatres the voice trial must be passed, and 35*s.* a week is an average salary to begin.

Salaries differ much in travelling companies.

Stockbroking. No indenturing and no premiums. A youth usually passes four years as house clerk without salary. In the Stock Exchange (*i.e.*, in London), which the provincial exchanges follow, a new rule stipulates that two years as house clerk and two years as settling room clerk may constitute qualification for membership. After four years' service in the House, a clerk may become a member by committee nomination or by purchasing a nomination (price £100–£120) if he acquires at same time one Stock Exchange share (value about £230). Employes frequently earn only £80 a year salary, but by commissions on business introduced to their employers often aggregate handsome incomes. Capital is essential to beginning business of stockbroker, as much business is financing. Practically no limit to possible income of successful stockbroker. Some London brokers earn not less than £50,000 a year. The physical and nervous strain of the work is very great.

Teaching. The teacher in an elementary public school usually begins as a pupil-teacher at sixteen. Apprenticeship lasts four years, and includes part-time teaching. Boys receive 5*s.* to 12*s.* per week; girls, 3*s.* to 8*s.* a week during pupil-teachership. Examinations are held during the apprenticeship. The King's Scholarship examination must follow immediately on completion of pupil-teachership or later. Two or three years in a training college usually follows. Tuition and lodging cost £25 to £30 for the two years, but not less than £5 a year is necessary for books and other expenses. After passing from college, and after eighteen months' probation in an elementary school, the teacher receives his *parchment*, and is *trained*. The assistant master in a public elementary school in the provinces begins at about £85, and rises to £150. In London the minimum is £95 and the teacher can rise to £200. Teachers in Church Schools receive much smaller salaries, the average being only about £70. Public elementary school male teachers average £130; women average £80. Salaries of headmasters in London Schools vary from £175 to £400; those of infants' and girls' headmistresses between £140 and £240 or £300. Provincial salaries are on a somewhat lower scale. Under London County Council scale an untrained teacher can commence at £90 and go up to £160. In the provinces an untrained teacher's salary is about £20 or £30 less than a trained teacher's. Uncertificated teachers are not now appointed under the London County Council, but are numerous in the provinces.

In Secondary Schools a university degree is necessary, and the highest appointments are usually given to Oxford or Cambridge graduates. Assistants in secondary schools earn from £100 to £700, the average being from £200 to £350. The headmasters of the chief schools, such as Eton, Winchester, Harrow, and Rugby, receive from £3,000 to £8,000 a year with residence. In others, like the City of London, the salary is from £1,000 to £2,000.

see page 321

THE PLAN OF THE VEGETABLE KINGDOM

The Wonderful Scheme of Nature. Kingdoms and Sub-Kingdoms of the Vegetable World. Scientific Grouping of Flowers and Plants

By Professor J. R. AINSWORTH DAVIS

IT forms no part of the plan of this course to give elaborate details regarding the classification of plants, and students who wish to find out the names of common forms are advised to consult the ordinary systematic treatises. We must, however, even at the outset, acquaint ourselves with the main subdivisions of the vegetable kingdom, beginning with the highest, as these will form convenient headings under which the facts to be considered may be arranged in an orderly fashion.

Each of the largest subdivisions is termed a *phylum* (or *sub-kingdom*), the further subdivisions being *sub-phylum*, *class*, *order*, *sub-order*, *genus*, and *species*. With the last five we are not at present concerned. It is also convenient to use the word *group* in rather a loose sense, where plants that are not necessarily closely related are associated for some special reason, facilitating their study.

PHYLUM 1. FLOWERING PLANTS

[*Phanerogams* or *Spermaphytes*].

This phylum includes the great bulk of familiar plants, whether trees, shrubs, or herbs. They all possess *flowers*, which are commonly, though by no means always, conspicuous. These may broadly be considered as special arrangements which have to do with the production of seeds, and a *seed* is a reproductive structure containing a dormant plantlet, which under favourable circumstances is able to grow into a new plant. The seed is, so to speak, a special device for tiding over the unfavourable season of the year. The plants of this *phylum* are provided with roots, stems, and leaves, all of which are *vascular*, *i.e.* they are traversed by tough strands (aggregated into vascular bundles), which serve as a supporting internal skeleton, and also conduct sap. The so-called "veins" of a leaf are good examples of such bundles, and the stringiness of old beans is due to their presence in an unwelcome degree.

Sub-Phylum 1. Pod-plants [*Angiosperms*]. The large majority of Seed-plants belong to this subdivision, in which the seeds are protected by being enclosed in some sort of case, such as the pod of a pea or broom [18],* or the large hard capsule of a poppy, such as may be seen in any chemist's shop. Other examples are afforded by the seeds (pips) of an apple or orange.

Sub-Phylum 2. Naked-seed Plants [*Gymnosperms*]. Though sufficiently well protected, the seeds are not here enclosed in a special case. Of this we may be convinced by pulling to pieces the cone of a fir [16], pine, or larch, when a couple of seeds will be discovered on the upper side of each scale.

* For Figures 1 to 18 see coloured frontispiece.

As a matter of convenience all the remaining phyla may be collectively spoken of as constituting the great group of *Flowerless Plants* (*Cryptogams*), *Seedless Plants*, or *Spore Plants* (*Sporophyta*), as they have been at various times called. The second name, however, is the only one of the three which is not open to grave objections, as we shall subsequently see, though it is most usual to speak of *Cryptogams*, and there is no harm in using the word as a mere label. Neither conspicuous coloured flowers nor seeds are present, and the typical means of propagation is by means of spores. Everyone must have noticed brown patches on the backs of fern-fronds, and if these are examined under the microscope it will be found that they are made up of little cases filled with minute grains [13]. These are the *spores* which are able, under favourable conditions, to produce fresh plants.

PHYLUM 2. FERNLIKE PLANTS

[*Pteridophytes*].

The Fernlike plants or Vascular Cryptogams, of which Phylum 2 consists, are the highest Cryptogams, which agree with seed-plants in the possession of roots, stems, and leaves, traversed by vascular bundles. Ferns of all kinds are the most obvious examples of the phylum [13], which also includes the club-mosses of mountain and moorland, the horsetails of swampy ground [14], and certain other plants.

PHYLUM 3. MOSSES, LIVERWORTS

[*Bryophytes*].

Neither roots nor vascular bundles are present. The familiar mosses [12], though capable of surviving a large amount of desiccation, only thrive in damp places or during the wetter parts of the year, and their lowly relatives, the *Liverworts* [11], are for the most part markedly moisture-loving plants. In some of these there is no division into stem and leaf, the plant-body being a flat green expansion or *thallus*. Liver-worts may often be noticed on damp earth in early spring, in shady corners near brooks or waterfalls, or covering the damp crannies of wet hedge-banks with their sheets of green.

PHYLUM 4. PRIMITIVE PLANTS

[*Thallophytes*].

Here is included a vast assemblage of lowly forms, some conspicuous, but many microscopic, in which the plant-body is a thallus of various shape; a group widely distributed all over the globe, from the surface of the polar snows to the gloomy abysses of the sea. This Phylum divides itself into three groups.

Group 1. Algae. Like all the plants above them in the scale, these forms contain a

very characteristic green pigment (*chlorophyll*), which renders it possible for food of very simple character to be built up into complex compounds, which furnish the material for the renewal and growth of protoplasm. Most of these lowly plants are aquatic. They include the green sea-weeds [6], flat or threadlike, which abound in tide-pools on the sea-shore, and their fresh-water allies that are often to be seen as a green scum or as masses of slimy threads in stagnant ponds. The powdery green investment on the trunks of trees or wooden palings, or even in roof-gutters, consists of microscopic green *Algæ*, which are also abundant in marine or fresh-water mud. These last belong to a special class (*Desmids*), characterized by their elegant shape and often by their powers of movement [5].

Though *algæ* always contain *chlorophyll*, it is often obscured by the presence of pigment of some other colour, as in the brown sea-weeds, which cover the "between-tide" rocks, or make up huge floating masses in certain parts of the ocean (*gulf-weed*). We have also the beautiful red sea-weeds cast up by storms upon the shore [6].

From the artistic standpoint, by far the most attractive *algæ* are the microscopic *Diatoms* [4], which swarm in the sea and in fresh water, and are of the most varied shapes. They possess a flinty skeleton, often sculptured with regular geometrical patterns of the most intricate and beautiful kind, which reveal fresh marvels as they are viewed with successively higher powers of the microscope. Many a would-be scientific amateur, fascinated by their charm, has ended by becoming a hopeless "diatomaniac."

Group 2. Fungi. The plants so far considered all contain *chlorophyll*, and this is only able to exercise its peculiar function in the presence of light. But as *fungi* are devoid of this colouring matter, they are quite independent of light, and hosts of them live and thrive in perfectly dark places, feeding during the night as well as throughout the day. We may say, in fact, that these plants are adapted to occupy places that would otherwise be devoid of plant-life altogether. To this power there is, however, as a general rule, one drawback, *i.e.*, the food must be of a more complex nature than that of green plants, and we find that fungi are in ordinary cases dependent upon the organic matter formed by the death and decay of other organisms, or else that they prey upon the living bodies of these. In the former case they are known as *saprophytes*, in the latter as *parasites*.

Mushrooms and Toadstools [7, 8]. These are the most conspicuous and perhaps therefore the most familiar fungi. What we call a *mushroom* consists of innumerable microscopic threads compacted into a stalk bearing a rounded expansion, on the under side of which are a number of radiating pink or brown plates known as *gills*. If the top of a mature mushroom is placed on a sheet of white paper, left for some time, and then lifted up, we shall find on the paper a coloured radiating pattern following the arrangement of the gills to the most minute detail, and inspection shows that the pattern is traced in a sort of impalpable dust. This dust consists of an infinite number of *spores*, which have fallen from the gills, and the so-called mushroom is simply a spore-producing arrangement. The actual plant-body of the fungus is in the form of a branching mass of whitish threads which run through the underlying soil, making up what the gardener knows as *spawn*.

Moulds, Mildews, etc. Food, leather, and many other things, if kept in damp places which are warm and dark, are apt to become "mouldy" or *mildewed* owing to the growth of various fungi. One of the commonest forms of these is "green mould" [3], such as may often be seen on damaged oranges, while "blue mould" attacks some kinds of cheese. In either case the plant-body is a mass of branching threads, from which special spore-bearing branches rise up into the air. Many diseases of crops—*e.g.* the well-known *potato disease*—are due to the attacks of somewhat similar fungi.

Yeasts. The alcoholic fermentation of beer or wine is brought about by the presence of hosts of microscopic fungi, spheroidal or egg-shaped, and mostly propagating by means of budding, though spores may also be formed under some circumstances. Any number of them can be seen in a drop of liquid yeast [2], or "barm," placed under a fairly high power of the microscope.

Bacteria. These excessively minute fungi [1], which are of numerous forms, rod-shaped, spherical, spiral, etc., are dealt with fully in the course on Bacteriology. They propagate by transverse splitting (*fission*) and also by spores, and play a very important part in the economy of nature. Many infectious diseases—consumption, typhoid fever, cholera, leprosy, etc.—are brought about by them, and putrefaction or decay is due to their presence. On the other hand, they are of great importance in the "ripening" of milk and the maturation of cheese, in the formation of acetic acid and the preparation of flax, and so on. Many of them take part in the cycle of chemical changes which is constantly going on in the soil, and they have much to do with the successful raising of crops.

Group 3. Lichens. All are familiar with the grey and yellow incrustations on stone and bark [9, 10], and the branching grey or greenish tufts on many trees, which go under this name. It is only necessary to say here that every *lichen* is a sort of compound or joint-stock organism, consisting of an *alga* and a *fungus* in intimate association. The former does the feeding, while the latter is concerned with the production of spores, which are formed in flat or cup-shaped structures.

THE SCIENCE OF A PLANT

The meaning of the lavish profusion in form and other characters of the higher plants will best be understood if we first briefly review the essential features of a typical example, endeavouring to find the use of every detail of every part, the physiological meaning of every character. Nature is essentially utilitarian.

and even such things as the colours and scents of our favourite flowers are not to be interpreted as merely ministering to human tastes, but as being of the greatest practical importance to their possessors.

The Struggle for Existence. So numerous are the differences between the well-nigh innumerable species of seed-plants—and the remark applies to the other phyla—that any attempt to find a clue to guide us through the maze would be well-nigh hopeless were it not for the fact that they are all constructed on one common plan, it being indeed a case of "unity in variety." This variation in all sorts of ways has been brought about by the keen struggle for existence which everywhere takes place, and may be observed in any tangled hedge-row or rankly-growing meadow, in the deep recesses of the tropical forest, and the dense covering of the heather-clad moorland. It is a struggle for bare foothold, a competition with other plants for food and light, a perpetual endeavour to resist the unfavourable influences of weather and the attacks of animal foes. It is not merely a struggle for the maintenance of the life of the individual, but for a continued existence of the species, for the production of healthy seeds which may in their turn have some chance—albeit a small one—of carrying on the never-ceasing warfare in their turn.

Hence have gradually been evolved [see BIOLOGY] all sorts of shapes and forms, differences in size and habit, diversities in colour and odour, and endless modifications in structural detail, all having to do with the maintenance of the existence of the individual or of the species.

Fundamental Plan of Structure. It will therefore be apparent that our study of seed-plants may best be begun by considering the *fundamental plan of structure* which dominates the almost endless differences in detail. We have already made a start in this direction by enumerating the leading features which enable us to define the phylum. Where—as in an ordinary course of Botany—theoretical and practical work are associated and co-ordinated, it is a usual and desirable practice for certain actual common *types* of plant to be carefully worked out in the laboratory as regards form and structure. Here, however, in order the better to perceive the general plan, and to avoid being led into side-paths by comparatively unimportant matters, it will be well for us to consider a *theoretical type*, or *pattern plant*, mentioning actual species where it seems advisable for illustration.

Life of the Individual. In our pattern plant [19] we shall find an underground part, the *root*, and an overground part, the *shoot*, which consists of a *stem* bearing *leaves*. Both root and stem are more or less branched, each branch of the latter arising in the angle (*axil*) at the base of a leaf. The branching form is very characteristic of higher plants, and the reason for it is not far to seek. In order to live and grow, a plant must feed and breathe. Its food consists of liquid taken from the soil and gas from the air, to absorb which a large external surface is necessary. Breathing, on the other hand, involves the absorption of oxygen gas, while at the same time carbonic acid gas passes out to the exterior, so that here, again, surface area is of importance. It is obvious that an increase in surface, so advantageous for both feeding and breathing, is conveniently brought about by branching of the stem and root.

The Root. As the work of the root has to be done in the ground, it is not surprising to find that it reacts positively to the action of gravity and negatively to that of light—*i.e.* its direction of growth corresponds with the downward pull of gravity, and it may be said to shun the light. The main root goes vertically downward, while the side-roots are more or less oblique. Moisture also exerts a strong attraction. During the life of the plant a root continually elongates owing to active growth at its tip, which is provided with a *growing point* full of *protoplasm*, and covered by a thimble-shaped sheath known as the *root-cap*, which prevents the surrounding particles of earth from injuring it.

The root anchors the plant in the ground, supporting the stem and leaves. The branching form is clearly adapted to this use, while the size and extent of the root-system are proportionate to the weight of the parts above ground which require to be held up. As a plant increases in size its roots not only become longer and more numerous, but also—in many cases—gradually thicken. It also appears that from time to time they contract longitudinally, being thus drawn taut—which contributes in no small degree to their effectiveness as means of fixation.

Each root is traversed by a *central core*, largely composed of longitudinal woody fibres of great toughness, and thus able to withstand the very considerable pull that is brought to bear upon them in windy weather. Examination of any large forest tree that has been torn up by a storm will at once show the size and complexity of the root-system.

The Food of the Plant. Ordinary earth consists of particles of various size to which films of water cling, and this water constitutes a large part of the food of the plant. It contains small quantities of various mineral matters in very dilute solution, so much so that a comparison may be made with ordinary drinking water.

The nature of the food which is taken up from the soil can be readily determined by growing plants in artificially-prepared solutions [20]. Water itself is of the first importance, for not only is it abundantly present as such in the living plant, but it supplies two of the chemical elements—hydrogen and oxygen—which enter into the composition of protoplasm, and are also essential components of many substances which are the products of vital activity, *e.g.*—wood and starch. But a plant will not grow and thrive if its roots are supplied with nothing but pure water. There must also be small quantities of simple mineral compounds containing seven other elements, *i.e. Nitrogen, Sulphur, Phosphorus, Potassium, Calcium, Magnesium*, and *Iron*. At least the first three of these help to build up protoplasm, while the others are of importance in various ways.

Some plants require still other kinds of food for their complete well being. A well-known example is afforded by the grasses—including our cereal crops—which contain a considerable amount of flinty matter or *silica* (SiO_2) in their stems and leaves, taking this up from certain siliceous compounds in the soil. Apart from cases like this, plants differ considerably among themselves as to the exact composition of the food they require, which is one reason why it is desirable for farmers to adopt a *rotation of crops*, instead of growing one kind of plant continuously in the same field. Since a given soil may from the first be deficient in one or other of the essential kinds of plant-food, or may have become "exhausted" of its supplies, the necessity for manuring also becomes apparent. In such matters expert advice is clearly a desideratum. [See AGRICULTURE.]

The Root as Food Finder. The work of taking food up from the soil is done by the younger parts of roots, especially their ends, and a few details on the structure of roots here becomes necessary. All but the lowest plants are made up of large numbers of variously-shaped fragments of protoplasm known as *cells*. These are usually of microscopic size.

A typical cell [21] is covered by a delicate elastic membrane, the *cell-wall*, composed of a substance (*cellulose*), with which everyone is familiar in the form of cotton wool. Within the wall is a layer of protoplasm surrounding a relatively large space full of fluid, the *cell-sap*, and often traversed by protoplasmic strands. A small part of the protoplasm is specialized into a rounded *nucleus*, which plays a very important part in controlling the life of the cell. It must also be noted that the living healthy cell is turgid, *i.e.* in a state of distension, so that the elastic cell-wall is on the stretch. An aggregation of similar cells is a *tissue*.

The outer part of a young root (*cortex*) is composed of layers of cells, resembling in essential particulars the typical one just described. Those making up the outer layer are drawn out into slender tubes externally, and constitute what are known as the *root-hairs* [22]. It is these which take up the food-solution from the surrounding soil, by means of *osmosis*, a name which is applied to the well-known physical process of diffusion of liquids through *membranes*. Or, in other words, if two different liquids are separated by a thin moist membrane, each of them will soak or diffuse through the membrane. In this case the two fluids are the food-solution outside the cell and the cell-sap within it, while the moist membrane is represented by the cell-wall. As the incoming fluid here largely exceeds in amount that which goes out, the plant is a continual gainer. The fluid thus gained, or part of it, now diffuses into the next layer of cells, and so on, until the central core of the root is reached.

How the Root Feeds Itself. The cell-sap, which diffuses out of the root by means of osmosis, is slightly acid, and helps to dissolve the particles of the soil, *i.e.* assists in the preparation of more food. This is facilitated by the fact that the root-hairs come into very close contact with the particles in question. This "*self-help*" on the part of roots is very prettily illustrated by placing a polished slab of limestone in the bottom of a flower-pot in which a plant is growing. After a time the roots will spread over and corrode the limestone, etching their outline upon it.

It will be convenient to speak of the watery mineral solution of food taken in from the exterior as the *crude sap*. This is conducted upwards by the central *vascular core* to which allusion has already been made. The actual structure of this is very complicated, and it is enough to say here that part of it consists of elongated woody strands, formed by the alteration and elongation of cells. They have altogether lost their protoplasm. Some of them are continuous tubes or *vessels*, made up from longitudinal rows of cells from which the transverse party-walls have disappeared. The exact way in which conduction of crude sap takes place is imperfectly understood. It is partly due to capillary attraction, and *osmosis* pushes from behind, so to speak. As the vascular bundles of the root-core are continuous with those of the stem, and these, again, with those of the leaves, we have a definite path provided for the upward current of crude sap.

Like all living parts of the plant, the root breathes, but as the leaves are of greatest importance for this kind of work, it will be well to postpone consideration of the nature and meaning of this process.

The Stem. The stem of the plant is charged with the office of displaying the leaves to the best advantage, and of serving as the means of communication between them and the root. As we might naturally expect, it reacts negatively to gravity and positively to light, growing away from the earth, and avoiding darkness. The main stem typically assumes an erect position, while the branches are directed obliquely upwards. The positive action of light is well seen by cultivating a box of mustard and cress in a window, when the seedlings will be found to bend away from the relatively dark interior of the room.

The main stem and its branches continually elongate [23], in much the same manner with the root, except that the delicate growing parts at their tips are not protected by caps, but by the undeveloped leaves, which are folded over them. When the life of a plant is indefinitely prolonged it frequently happens that the stem regularly increases in thickness, thus enabling it to bear the increasing weight of the over-ground parts. This is best realized by examining the cut end of a tree-stump, when the wood will be found to be arranged in concentric annual rings, of which one is formed each summer, external to those which already exist. The number of such rings may amount to several hundreds, or even run into four figures.

Structure of the Stem. Examination of a cross-section of the stem of our pattern plant [24] will show that it is covered by a layer of flattened cells, the *epidermis*, of which the outer cell-

walls are thickened as a means of protection. Some distance within this we shall see a ring of *vascular bundles*, each of which consists internally of *wood*, and externally of *bast*, while between the two there is a narrow zone known as the *cambium*. The *wood* is made up of elements resembling the woody fibres and vessels of the root, while the *bast* is essentially composed of elongated *bast-vessels*, formed by the modification of cells. Their walls are not of woody nature. Their most important use is to conduct downwards the prepared food or *elaborated sap* which is prepared by the leaves, and they are continuous wi h similar elemen's found in the vascular core of the root and the vascular bundles or veins of the leaves The *cambium* is a thin layer of elongated actively dividing cells, with thin walls and abundant protoplasm

The Stem as a Means of Support. The rest of the stem is composed of more or less typical cells, of which those in the cen're make up the *pith*, those external to the bundles the *cortex*, and those between the bundles *the medullary rays*, by which cortex and pith communicate The structure of a thickened stem, is, of course, much more complicated

The stem is divided into *nodes* -from which leaves and branches arise and intervening parts, the *internodes* In order to hold up the leaves, especially during windy weather, it is clearly of advantage that the chief mechanical tissue, *i e* the vascular bundles, should be arranged in an advantageous manner Hence the ring like disposition seen in the cross section, which gives much greater resisting power than would be attained by a massing together in the centre Greatly increased firmness is brought about by transverse and oblique bands, which unite the bundles girder fashion at the nodes Nature thus establishes her humblest creations upon foundations more perfect than any which man can devise

The possession of a considerable amount of elasticity is another important point deserving attention Some plants, such as grasses, have internodes which attain the maximum of strength with the minimum expenditure of material For each of them contains a large central space, and the well known mechanical principle of the hollow column is thus exemplified. A piece of bamboo shows this to perfection. In young and juicy stems the pith and cortex contribute even more to effective support than do the vascular bundles. For the distension of the walls of their cells by sap results in firmness combined with elasticity When such plants wither their limp condition is brought about by the loss of water

The Leaf. Leaves are flattened outgrowths from the *nodes* of the stem, with which their tissues are completely continuous. They are of various kinds, but the ones with which we have here to do are the *foliage leaves*, to which alone the term *leaf* is applied in ordinary language

A fully-developed leaf [26] consists of a flattened *blade*, borne upon a *stalk*, at the base of which there is very often a pair of flattened outgrowths known as *stipules*. These last, however, are often absent, and many leaves are also destitute of stalk. In some cases, *e.g.* grasses, the attached part of the leaf is in the form of a *sheath* which wraps round the stem. Leaves present almost endless variations in shape, proportion, and mode of arrangement on the stem.

The leaf-stalk closely resembles the stem in structure. Turning to the more important leaf-blade [26], we find externally a protective layer of *epidermis*, which is very tough and firm in some cases, as in the leaves of holly and laurel As the blade is horizontally expanded, we can distinguish between upper and lower epidermis It is characteristic of the latter that it should be perfora'ed by a large number of minute holes, by means of which the interior of the leaf is placed in communication with the exterior Each such pore is known as a *stoma*, and it is bounded by two guard-cells, which are capable of altering their shape so as to vary the size of the slit between them Stomata are also found in the epidermis of young stems, nor are they necessarily confined to the undersides of leaves In the floating leaf of a water lily, for example, they are only found in the upper epidermis, which is next the air

The Lungs of the Plant. Between the two layers of epidermis there is a mass of green *cellular tissue*, divisible into an upper layer of cells elonga'ed at right angles to the surface thus giving an appearance which has earned for it the name of *palisade layer*—and a lower *spongy layer*, which exhibits no such regularity Between the cells of the spongy layer are air spaces, which form part of a continuous system of narrow chinks and passages by which the plant is traversed If the blade of a thick stalked leaf is immersed in water, the existence of this continuous set of air passages may be demonstrated by placing the cut end of the stalk in the mouth and blowing into it as hard as possible Minute bubbles of air will then be seen to come off from definite points on the leaf-blade, having made, in fact, their exit through stomata The cells of both palisade and spongy layers contain numerous specialised rounded particles of protoplasm coloured green by chlorophyll These are the *chlorophyll granules* [27A]

The veins of the leaf blade are its *vascular bundles*, consisting of wood above and bast below These bundles are so arranged as to prevent the leaf from tearing easily, while at the same time they guard against the collapse of the delicate green cellular tissue, by keeping the two layers of epidermis well apart

We have seen that the food solution taken in by the root contains nine chemical elements which are essential to the life of the plant, but there is still one other which is indispensable—*carbon*, which is one of the components of protoplasm, as well as of cellulose, wood, and many other characteristically vegetable substances The source from which this element is obtained is carbonic acid gas or *carbon dioxide* [CO_2], which makes up a small percentage of the atmosphere. One of the uses of the stomata is to permit this gas to pass readily into the interior of the leaf.

SKETCHES ILLUSTRATING BOTANICAL STRUCTURE AND PLANT LIFE

How the Plant Uses Sun-power. The food of the plant consists of the simple substances already mentioned, *i.e.* *carbon dioxide*, *water*, and small quantities of mineral matter. These have to be built up step by step into organic compounds till, in the end, living substance, or *protoplasm*, is produced. The early steps in this process—which bridge over the gap between non-living and living matter—can only be effected—by protoplasm itself—in daylight with the co-operation of *chlorophyll*. This is the most important duty of the green part of the leaf, which is aided in the work by the green outer part of the stem.

A chemical reaction takes place between the water [H_2O] which the leaf receives from the root and the *carbon dioxide* [CO_2] it takes in from the air, resulting in the formation of an organic substance composed of carbon, hydrogen, and oxygen, a formation which could not be effected were it not that *chlorophyll* enables the energy of sunlight to be utilised for the purpose. In other words, though the protoplasm of the leaf does the up-building work, it has to use *sun-power* for the purpose, and *chlorophyll*—how, is not clearly understood—alone renders this possible. If kept in the dark, a green plant soon becomes pale and sickly, for its constructive work is arrested.

Starch. The further steps in the formation of plant-substance are too complicated to be followed here, and it is enough to say that the first visible product is *starch*, another compound made up of carbon, hydrogen, and oxygen. That grains of this substance are actually formed in the leaf can be proved by microscopical examination, and also by a simple chemical test. It is a well-known fact that starch turns blue when subjected to the action of a solution of iodine [in *potassium iodide*—(KI)], which can be obtained from any chemist. If we take a leaf that has been exposed to the sun for some time, and place it in this solution, it will rapidly become of a dark blue colour, thus proving the presence of starch. By pinning two round pieces of cork to part of a leaf [27A], one above and one below, we can keep off the sunlight and thus locally prevent the formation of starch. If a leaf of which part has thus been shaded is placed in the iodine solution, the part in question will not turn blue, thus showing that no starch is present. It may be added that the palisade layer of the leaf is of most importance in the constructive work just described.

Oxygen from the Leaf. When any organic substance is formed in the green parts of a plant by chemical reaction between water and *carbon dioxide*, a large part of the oxygen contained in these substances is not required for the purpose. This, as a sort of bye-product, passes into the surrounding air, which we know is a mixture of gases, about 21 per cent. being oxygen, an element which is constantly being used up in the breathing of animals, and also in combustion.

A convenient way [28] of demonstrating that oxygen is given off during the feeding processes of green plants is to put some water-plants in a glass vessel, covering them with a funnel, and placing an inverted test-tube full of water over the stem of this. If the whole arrangement is now exposed to light small bubbles of gas will soon be seen to rise from the plants, gradually filling the test-tube. By applying the usual tests it is easy to prove that this gas is actually oxygen. If, for example, a glowing splint of wood is plunged into the tube it will be at once re-kindled.

The Organic World at a Standstill. Were it possible to destroy all existing *chlorophyll*, and to prevent the formation of more, the organic world would soon be brought to a standstill, and life would become extinct. For no more plant-substance could be built up from non-living material, and the vegetable world would therefore soon cease to be, while, as animals directly or indirectly depend on plants for food, they, too, would quickly die out.

Quite apart from this, the breathing of plants and animals, and the processes of combustion, continually exhaust the oxygen of the air and increase the proportion of poisonous *carbon dioxide*. The composition of the atmosphere is, in fact, only kept normal by the utilization of carbon dioxide as food by green plants, with concomitant liberation of oxygen. As we have seen, this process is absolutely dependent upon chlorophyll.

Starch—converted into soluble sugar—and certain other organic substances, are constantly being drained off from the leaves, as *elaborated sap*, to all parts of the plant, serving for the repair of waste and the furtherance of growth. They partly diffuse from one living cell to another, and partly travel along the bast-vessels of the vascular bundles.

Transpiration of the Leaf. The leaf, and the stem to a less degree, are constantly giving off water vapour—*i.e.*, *transpiring*. This vapour is continually evaporating from the delicate green cells of the leaf into the adjoining air-spaces, from which it makes its exit by means of the stomata. That transpiration actually takes place is shown by the way cut leaves wither, and may easily be demonstrated by placing several such leaves with their stalks in a glass of water, which is then covered by a glass plate. If the whole is now put in a sunny window moisture will gradually accumulate on the under side of the glass plate.

An easy and pretty experiment to prove that transpiration takes place from the *under* side of the leaf, where the *stomata* are situated, can be made by taking advantage of the fact that cobalt paper [prepared by drying blotting-paper that has been soaked in a 5 per cent. solution of cobalt chloride], which is blue when dry, turns pink on being moistened. A piece of this paper is placed on a glass plate, and covered with a perfectly dry leaf under side downward. A second piece of cobalt paper is then put on the upper side of the leaf, and a second glass plate over all. After exposure for a short time to sunlight it will be found that the paper which has been in contact with the *under* side of the

leaf has become pink, while the other piece retains its blue colour.

Use of Transpiration. The promotion of the upward current of crude sap is of the utmost importance, for the amount of mineral matter dissolved in it is so small that a constant stream is necessary to furnish the leaves with the requisite amount for their constructive work. Some of the causes of the upward flow of sap have been mentioned in dealing with the root, and transpiration would appear to be a supplementary agency, for the loss of moisture by the leaves must promote the ascending current.

Organisms are constantly and necessarily undergoing disintegration, thereby setting free the necessary energy for the conduct of the various vital processes. This down-breaking process is essentially one of *oxidation*, a kind of combustion, comparable in a broad sense to what takes place in a fire. Hence the necessity for a supply of oxygen, derived from the air. Breathing or Respiration is in fact the taking in of oxygen, together with the elimination of carbon dioxide, which is one of the useless products resulting from the process of disintegration.

Breathing of Plants and Animals. It is very generally but erroneously imagined that, while animals take in oxygen and give out *carbon dioxide* in the process of breathing, the reverse is true for plants. As a matter of fact, both breathe in precisely the same way. But, as we have seen, a green plant is constantly giving off large quantities of oxygen during the day, as a bye-product of its feeding processes. And this has been mistaken for a product of respiration. In reality, some *carbon dioxide* is also given out as the plant breathes.

During the night, when the evolution of oxygen ceases, owing to the absence of light, it is easy to prove that a plant breathes exactly like an animal. Place a vigorously growing pot-plant at night in a cylindrical glass vessel just large enough to hold it, and close the mouth of the vessel by a greased glass plate. To prevent access of light it is best to put the jar with its contents in a dark cupboard. If, next morning, a lighted taper is plunged into the jar it will be extinguished, showing that the oxygen of the air has been used up and that carbon dioxide has presumably been given out. The latter point may be definitely established if a watch-glass full of lime-water has previously been placed at the bottom of the jar, for the liquid will be found to have become milky during the night. This is a well-known test for carbon dioxide.

The Fight for Light. Leaves may be attached one or more at a *node*, those of two successive *nodes* not being situated vertically one above the other. They may be stalkless, or else possess stalks of varying length, and there are all sorts of possibilities as to the size and shape of the blade, which may not be uniform even in the same plant.

There are several reasons for this large amount of diversity, one being the necessity for advantageous display as regards light. The horizontal position of the leaf-blade in ordinary cases has obvious reference to the necessity for getting as much of this as possible, while the mutual arrangement of the leaves of the same plant is of such a nature that they screen one another from the light as little as possible. Hence the origin of *leaf mosaics*, which are well seen in the case of ivy growing on a wall, or the branches of many forest trees, such as beech or elm [29]. Examination of one of these plants will show that the leaves fit into the spaces between one another, so as to form a more or less continuous sheet of green. In tangled undergrowth the leaves often have to accommodate themselves to those of their jostling neighbours, which partly accounts for the much divided form they often assume.

The Unending Warfare of Nature. Many dominant plants secure part of the soil for their sole benefit by keeping away the light from other forms, which is tantamount to starving them out. But little can grow, far less flourish, under the dense foliage of many forest trees, while some herbs adopt aggressive tactics of another kind. The daisy, dandelion, plantain, and many other rampant weeds, possess a dense rosette of leaves resting on the ground, seizing, as it were, a small circular holding for their own exclusive use [30]. The arrangement is due to suppression of the internodes, whereby the leaves belonging to a considerable number of nodes are of necessity crowded together.

The dandelion, when growing in a meadow, is often in danger of being itself deprived of light by the luxuriant growth of the surrounding grasses. Under such circumstances the leaves of the rosette abandon their horizontal position and direct themselves more or less upwards. To make the most of the scanty light attainable it has to convert itself into what is termed a *shade-plant*, though it is more usually found growing as a *sun plant*, in the open waste places which are its favourite habitat. Not only do its leaves turn upwards towards the light, but they become larger and more delicate, while the characteristic deep indentations in their edges more or less disappear.

[DESCRIPTION OF THE FRONTISPIECE. The plate forming the frontispiece of this part of the SELF-EDUCATOR is dealt with in the earlier part of this article. The contents of the plate are: 1. Bacteria; several species. 2. Yeast: *Saccharomyces cerevisiæ*, after Vines. 3. Green Mould: *Penicillium glaucum* (Vines). 4. Diatoms: several species. 5. Desmids: several species. 6. Seaweed: *Melobesia polymorpha; Chorda lomentaria; Delesseria ruscifolia; Hiliseris polypodioides; Asperococcus Turneri; Fucus vesiculosus*. 7. Toadstools: *Coprinus atramentarius; Russula emetica; Agaricus muscarius*. 8. Fungus on Beech Stem: *Fistulina hepatica*. 9. Lichen on Fir Stem: *Parmelia parietaria*. 10. Tufted Lichen on Fir Branch: *Usnea barbata*. 11. Liverwort: *Marchantia*. 12. Mosses: *Polytrichum commune*. 13. Ferns: *Polypodium vulgare*. 14. Horsetail: *Equisetum arvense*. 15 and 16. Fir Stem and Fruiting Branch: *Pinus sylvestris*. 17. Beech Stem: *Fagus sylvatica*. 18. Broom and Fruit: *Cytisus scoparius*.]

To be continued

A SHORT DICTIONARY OF TERMS IN NATURAL HISTORY

See also A Short Dictionary of Biology on page 88

ALBUMINOIDS—Complex substances chiefly of carbon, hydrogen, oxygen, sulphur, and, sometimes, phosphorus.
Ambulacrum—A groove in the star-fishes which lodges the tube-feet.
Ampulla—The swollen part of a semi-circular canal in the internal ear of vertebrates. Or a small sac connected with the tube-foot.
Atavism—The appearance of a trait unlike the immediate parents, but resembling a more remote ancestor.

BARB—One of the branches of a feather.
Biconcave—Hollow on both sides like the vertebra of a fish.
Bivalve—The shell of a mollusc when composed of two parts.
Brood-parasitism—A habit of some animals, such as the cuckoo, of placing their young with other parents.

CALYX—The outermost leaves of a flower.
Cephalopods—The cuttle-fishes, and their allies.
Cetacea—The order of mammals which includes the whales.
Cheiroptera—The order of mammals which includes the bats.
Chelonia—An order of reptiles which includes the tortoises.
Chordata—All animals which possess a notochord.
Chrysalis—The motionless pupa of butterflies and moths.
Chyle—The fluid which results from the action of digestion upon food.
Coccyx—The end of the spinal column.
Cœlom—The body cavity.
Colloid—Substances which do not readily pass through membrane pores.
Ctenoid—Term applied to certain fish scales with the hinder margins fringed.
Cycloid—A term applied to those scales of fishes which have a circular, or elliptical, outline with an even margin.

DECIDUOUS—Structures which are shed during the life of an organism.
Diphyodont—Applied to mammals which have two sets of teeth.

ELYTRA—A beetle's anterior wings.
Entomophilous—Flowers which are fertilised by insects.
Eozoic—The earliest geological period.

FLORA—The plants of any region.
Furculum—The "merrythought" bone of birds formed by the union of the two clavicles.

GANOID—Those scales in fish which have an inferior bony layer.
Gastrula—A term applied to that stage of the embryo which exhibits a double layer with mouth and digestive cavity.
Germinal disc—That part of the egg which develops into the embryo.
Gill-cover—The flap which overlaps the gill slits in fishes.
Gonophore—A bud in which the egg cells, or sperms, are produced.

HETEROCERCAL—The unequally-lobed tail in fishes.
Hock—The ankle in a horse's hind limb.
Homocercal—Equally-lobed fish tails.

INFUSORIANS—A class of the protozoa.
Insectivora—An order of mammals.

KAINOZOIC—The most recent geological epoch.

LACERTILIA—The order of reptiles including the lizards.
Lepidoptera—Order of insects which includes butterflies and moths.

MAMMALIA—The class of vertebrates which suckle their young.
Mantle-cavity—The space in molluscs which contains the gill, and into which the excretory organs generally open.
Marsupials—An order of mammals.
Medusa—The egg-producing stage of a jelly-fish, usually free swimming.
Mesozoic—The geological epoch which preceded the kainozoic.
Mongrel—A cross between two varieties of the same species.
Monœcious—Those individuals in which the two sexes are united.
Monophyodont—Mammals which develop only one set of teeth.
Monotremes—The lowest order of mammals.
Morula—An embryonic stage in which the segmented ovum is not hollow, but solid.
Mule—A cross between a horse and an ass.
Muscle—A definitely shaped piece of flesh.
Mutualism—The association of two organisms for the benefit of both.

NAGANA—Fly sickness; a fatal disease of horses caused by a parasite which is carried by the tsetse-fly.
Nearctic Region—The northern part of the New World.
Neuter—Having no fully developed sex.
Normal—Conforming to the ordinary standard.
Nucleated—Possessing a nucleus.
Nucleolus—A minute body inside a nucleus.
Nymph—The active pupa of certain insects, the stage which hatches from the egg.

ODONTOPHORE—The masticating organ in molluscs and cuttle-fishes.
Operculum—The gill cover in many fishes, also the horny plate which closes the shell of some molluscs.
Opisthocœlous—Concave behind, as in some vertebræ.
Oriental region—Southern Asia, together with part of the East Indies, the Philippine Islands, and Formosa.
Otocyst—A vesicle filled with fluid containing some solid particles. A simple form of hearing apparatus, probably also a balancing organ.
Otolith—A hard substance inside the hearing organ.
Ovipositor—An organ at the hinder end of the body of a female insect by means of which holes are made in plants for reception of the eggs.
Ovule—The portion of a plant which becomes a seed after fertilisation.

PALÆONTOLOGY—The science which deals with fossils.
Perissodactyla—Hoofed quadrupeds which have an odd number (one or three) of toes.
Pineal body—A structure in the roof of the vertebrate brain which probably represents the remains of a dorsal eye in some reptiles.
Pinnate (or **Pennatiform**)—Feather-shaped.
Pisces—The class of fishes.
Pisiform—A small round wrist bone.
Placenta—The organ in the higher mammals which establishes the vascular connection between the mother and the fœtus; the after-birth.
Placoid—Irregular, thick, bony scales, such as found in sharks and rays.
Pleura—Serous membrane covering lungs of air-breathing vertebrates.
Pollex—The innermost digit of the fore-limb—in man the thumb.
Procœlous—Concave in front, as in some vertebræ.
Proglottis—A segment, or joint, of a tape-worm.
Pronation—The act of turning the palm of the hand downwards.
Pyriform—Pear-shaped.

RAPTORES—The birds of prey.
Recapitulation—The repetition of the successive ancestral stages in the development of an organism.
Rennin—A ferment in the gastric juice which curdles milk.
Resemblance—General: a harmony with surroundings, causing the organism to be inconspicuous. It may be protective or aggressive, or both. Special: a likeness to some particular object in the environment.
Reticulum—A network; the second division of the complex stomach of a ruminant.
Retractile—An organ which is capable of being drawn back.
Rodentia—An order of mammals, gnawers.
Rostrum—The suctorial organ formed by the appendages of the mouth in certain insects; any kind of beak.
Rotifera—The wheel animalcules.
Rudimentary organ—A structure which is not fully developed.
Rumen—The first division, or paunch, of the complex stomach of a ruminant.
Rumination—Process of cud chewing.

SACRUM—The part of the backbone with which the pelvic arches unite.
Scolex—Embryonic stage of tape-worm.
Sessile—Not supported by any stalk.
Setæ—Bristles.
Spermaceti—Liquid fat obtained from the sperm whale, contained in a deep depression in the side of the skull.
Spinnerets—Small projections on the under side of the abdomen of spiders, on which silk glands open.
Spiracle—The apertures of the breathing tubes in insects; also the single nostril, or blow-hole, of cetaceans.
Supination—The act of turning the palm of the hand upwards.
Suture—The line of union between two immovable parts, as in skull bones.
Swim-bladder—An outgrowth from the alimentary tube of some fishes.
Swimmerets—The limbs of crustaceans which are adapted for swimming.
Symmetry—Regularity of structure, which may be either radial or bilateral (having right and left sides).
Symphysis—The union of two bones in which there is very limited motion.

TÆNIA—An order of tapeworm.
Teleostei—The order of the bony fishes.
Tetradactyl—Having four digits.
Tortoise-shell—A product of the horny plates obtained from certain turtles.
Trichocyst—Minute rods found in some Infusorians which are projected from the outer layer of the body for defence.
Tunicata—The sea squirts.

UNIVALVE—The shell of a mollusc composed of only one piece, as in the snail.
Urostyle—The hindmost portion of the backbone of a frog.

WAMPUM—The shell money of the North American Indians.
Water-vascular system—An arrangement of tubes, as in star-fish, concerned with locomotion and respiration.

ZOOTOMY—The science of the anatomy of the lower animals.
Zymotic—A term applied to diseases which are contagious.

BUYING, STOCKING, AND SELLING

Three great essentials. Errors and Extravagance in Buying. Stock to Avoid. Terms of Payment. Important points to bear in mind.

By W. B. ROBERTSON

THERE are many points which are peculiar to certain trades, and these will be duly discussed in considering the departments to which they apply, but the broad principles which enter into successful business management are general, and capable of application to any branch of shopkeeping.

In every retail business, no matter how small, there are three departments. In large stores these departments may be divided; in small or medium concerns they are united. These departments are *buying*, *stocking*, and *selling*. Each of these, even in a small concern, may be reduced to a system. The more the shopkeeper introduces system to facilitate work, to prevent waste of time, space, and money, the greater will be the accruing profit. The statement may be a self-evident truth, but the small heed given to its teaching by so many shopkeepers in their daily practice is sufficient apology for its enunciation here. Let us go deeper into the subject, and apply our principles of system to the three business departments we have mentioned.

Buying. The most prominent quality in the man who buys should be caution. It is much easier to buy than it is to sell. The successful buyer is he who has the talent of selecting for his stock not primarily the articles he himself thinks best, but those which his customers and the general public will buy most freely. The ability to divest himself of personal predilection or—what is, in its result, much the same thing—the ability to make his own taste coincide with the tastes of his purchasers, is a gift difficult to acquire. It is largely intuitive, and is allied to a distinct type of mind. Experience gives the ability only in a measure. We have known business men, successful as salesmen, whose judgment in buying was so little to be trusted that their only safe course was to refrain rigidly from any interference in the buying department. Sometimes the ability to choose saleable merchandise may exist, but the person may still be a comparative failure as a buyer. He may have the inability to resist the temptation to buy far beyond his immediate needs and beyond the absorbing possibilities of his district. How often the commercial traveller makes the confession, "I have got something here I want to sell to Messrs. A and B. I know that A won't buy it, but I shall touch B about it, and am sure of placing a few gross with him."

The traveller who is wise in his generation to this extent exhibits one of the most successful qualities of a salesman—the power of gauging the individual leanings of his customers and working upon that power to his own purposes. But our immediate concern in this place is for the purchaser, whom we would warn of the pitfalls in his path.

Extravagance in Buying. With many men the passion for the appearance of doing an enormous trade is strong, and some have ruined themselves by a course of conduct into which the weakness has led them. We have in mind a case in point. In the Bankruptcy Court recently a retail chemist appeared for examination. He was a competent pharmacist, punctilious in attention to his business, which was large, and should have been profitable. When his stock came to be realised for the benefit of his creditors it was found that his cellars contained unopened packages of goods to the value of a year's turnover. These packages had accumulated during a period of years, and had been collected solely through the man's desire to acquire in the eyes of the wholesale trade a false importance as a buyer. In this particular case, however, the man was totally incapable of business, and his case is an extreme rather than a typical one. Not often, perhaps, is the consequence of the temptations of buying so dire in its results.

In trades which change with the seasons the need of a buyer who can gauge the buying power of his customers is supremely essential. The group of clothing trades is the most prominent in this class. We find that nearly every draper has his annual, semi-annual, or quarterly clearing sales. In some measure these are genuine sales of end-of-season goods and remnants, such as are unavoidable in any business. But much of the turnover of the sale consists of articles bought for the purpose of the sale itself. Those who buy these things in the belief that they are genuinely reduced goods labour under a delusion which the salesman finds it no part of his business to remove. Some people may hold that the moral problem enters into such proceedings, and upon this question we make no pronouncement. But the point we wish to make is that the smaller the quantity of ordinary merchandise thrown upon the sale counter and cleared off at less than cost price or at less than proper selling price, the higher is the ability of the buyer in estimating the purchasing power of his market.

Errors in Purchasing. Sometimes th errors made in purchasing are almost beyon belief, and indicate a negligence that is culpab and deserving of overloaded shelves of ba or unsaleable stock. We may point a moral an perhaps even adorn a tale by citing an instan of what we mean. There are in England ar Scotland, at the time of writing, many iro mongers to whom it is dangerous to menti the name of a certain inexpensive knife-clean The manufacturers of the particular article

which we refer succeeded in persuading retailers to purchase grosses of their speciality when dozens would have satisfied all needs. Simple calculation would have shown the merchant that he was buying enough knife-cleaners to provide one for every man, woman, and child in his town, and reflection would have proved the folly of buying in such quantities. These men have been sufferers from the persuasive eloquence of smart salesmen and from their own inability to take into consideration the factors which should govern any projected purchase.

Stock to avoid Buying. A successful buyer is he who conducts his business upon the smallest stock in relation to annual turnover. Many traders have a dread of being asked for anything which they do not have. Such men have a mistaken sense of responsibility towards the public. Their notions of business lead them to cumber their warehouses with goods which are asked for only, perhaps, once in a number of years, and the profit gained from the sale of such articles is in no way commensurate to the expense of buying and stocking them. It must be remembered that every ten-pound note spent in stocking the shelves with slow-selling articles curtails the possibilities of outlay in directions which might be more profitable.

Every buyer, in whatever trade, ought to be thoroughly familiar with the features, qualities, uses and prices of every article for which there is a possibility of request. He should have a collection, as nearly complete as possible, of trade lists arranged for immediate reference, and should be able to tell from the marks upon these lists the discounts or net prices, and show the enquirer the detailed particulars regarding any out-of-stock article. In most cases a properly organised system such as this will effect a sale. One advantage pertaining to the ordering of articles of infrequent request, only after the customer has placed a definite order for them, is that they may be delivered fresh and untarnished from the makers, whereas, if they had been stocked for months or years, they might have become soiled, or be otherwise deteriorated. The expense of special carriage upon goods in occasional demand is usually less than the interest on capital sunk in stocking them, plus the value of the room they occupy, and the frequent loss through deterioration or breakage.

Friendship in Business. An oft-quoted maxim states that there is no friendship in business. This is a hard saying, and it is not quite true. There is, there must be, and there always will be friendship in business. The relations of buyers and sellers, their obligations towards each other, and their frequent intercourse begin in mere acquaintanceship, but, if founded upon mutual respect and esteem, often ripen into friendship. But there is a half-truth in the statement that there is no friendship in business. No man should let his business suffer by reason of friendship. His liking for a firm or for its travelling representative ought not to cause him to continue his patronage of it if his business interests would be better served by changing his market. Other things being equal, business preference should, no doubt, follow personal preference, but to purchase from a friend at a price ten per cent. higher than that demanded by another house is equivalent to a gift of ten per cent. of the price of the package, unless there are compensating advantages in credit terms, delivery conditions, or quality of goods.

Terms of Payment. There is another department in merchant buying, or, indeed, in private or personal purchases, to which there is urgent need of attention. We refer to the terms of credit and payment. Some shopkeepers pride themselves upon having no outstanding obligations. They pay for the goods they receive whenever they have been placed in store. Unfortunately, such men, as every manufacturer and wholesale merchant know, are relatively few compared with the total number of shopkeepers. Error too frequently lies at the other extreme in the manner of payment. We shall consider the laggards later. To the "spot cash" men, the men who believe in immediate payment, we may put the query: "Are you sure that you always get value for your promptness?" When the terms are *three months' credit*, the man who pays cash for his purchases without a special cash discount is not acting fairly to himself. He is unduly generous. Money is worth something. Even the use of money is worth something, and it should be the business of the alert shopkeeper to get that value in return for money paid before the latest date allowable under the contract of sale. Very often the inducements offered by manufacturers in the way of cash discounts are inconsiderable. Especially is this so when the purchaser is of established credit, and the seller has more than enough money at command to serve his immediate needs. In such a case the purchaser should take his legitimate limit of credit. Only when the monetary consideration makes it worth his while should a purchaser pay before the account is properly due.

The Value of Cash Discounts. The vast bulk of commercial business is done by those buyers who have established themselves in the confidence of their merchants, and who run accounts varying with the respective customs of trade.

We do not at this moment dissect the body commercial and investigate the credit terms usual in the various branches of shopkeeping. We merely urge the principle which should decide the mode of payment when there is an option on the part of the debtor.

Let us assume, for the purposes of illustration, that a merchant purchases goods to the average value of £50 per month from a certain manufacturer. He runs an account which he settles regularly once in three months. These are the usual terms in the trade, recognised as convenient by both parties. But it may happen that by paying monthly the purchaser could secure 2½ per cent. higher discount. The terms

may be *net three months* and 2½ *per cent. monthly*, or 2½ *per cent. at three months' account* and 5 *per cent. monthly*. Both practices prevail in several classes of goods. In either case the man who accepts the monthly terms pays 2½ per cent. less than he who takes the full three months' terms.

In the case we selected for illustration—an account averaging £50 a month—the extra discount received during the twelvemonth would be £15. What has the buyer done to earn this money? He has merely employed £100 in what, divorced from the association which led up to it, would constitute a simple money-lending transaction. Consideration will show that more than £100 is never employed at one time. The result represents, therefore, 15 per cent. upon the money employed. This is the actual cash value of the earlier terms of payment. The case we have considered is a modest one—an account of £600 a year. If the business purchased, say, £6,000 worth of merchandise per annum, and the system of earlier payment with its accompanying higher cash discount were made to supersede the longer credit over all the accounts, the saving in hard cash would be £150 per annum.

In a modest provincial centre many businesses purchasing goods to the value of £6,000 a year are run on a rental of £150 per annum, so that in such a case the introduction of paying for higher discount will pay the rent of the premises. Even if bankers' accommodation were necessary to give the ability to adopt the system of earlier payment, and, say, 6 per cent. had to be paid for the advance, the gain would still be with the buyer. Experienced buyers are often astonished when they make a scientific examination of the subject of credit and elicit the real facts.

Laggards in Payment. The one thing the student of this course should set his face against from the beginning is the habit of the laggard in business, particularly in the matter of payment. For one who lags behind by misfortune there must, of course, be profound sympathy. Sometimes the circumstances under which he pursues his career are beyond his own control, and non-success is his misfortune and not his fault. Often, however, there is something wrong in his system of business. To the laggards who are in straitened circumstances through trading beyond their means we can only point out the risks they are running. The higher the flight the greater will be the fall; and much genuine business ability has passed through Carey Street merely through misjudging the strength of wing. When credit is always on tension, it is nearer the snapping point than when it is carrying only a normal strain. The outer side of the wall of business success is strewn with the remains of "vaulting ambition which o'erleaps itself," and is hurt by its fall. For the laggards from choice, those who can pay but who put off the hour of reckoning indefinitely or altogether, we have no word. We reserve our advice for those who are their unfortunate creditors.

Stock-keeping. The second great department of shopkeeping which we set out to discuss is stock-keeping. The general principles which ought to apply to the keeping of stock may be summarised in a few rules, upon each of which a commercial sermon might be written. Every scheme of stock-keeping should consider—

1. The accessibility of the articles.
2. Their display when desirable.
3. Their arrangement, so that when stock is low the shelves do not look unduly thin, nor when big are they confused.
4. Their arrangement so that shortages may be seen with the least possible delay and trouble, and so that stock may be taken with the least possible labour.

When a stock is large and varied, spreading itself over several warehouses or flats, its arrangement is a difficult problem. The difficulties are greatest when the business is too big to be handled conveniently as a small concern, and yet not large enough to arrange in distinct departments. An arrangement which gives immediate accessibility to stock is also difficult when the business is one in which both wholesale and retail trading are carried on and such businesses are numerous in the provinces. When the retail department is so small as to be almost negligible, and the locality not promising for its development, it may sometimes be well to leave stock keeping under the system most suitable for the wholesale trade. But where the retail side is important or deserving encouragement, separate stock for the retail trade should be kept.

Spoiled Stock. The fundamental difference between wholesale and retail stock-keeping is that in the former displayed stock is unessential, even undesirable, while in the latter open displayed stock or samples of stock are a most important factor in inducing sales. In a retail trade, further, the different articles should be stored so as to be ready at hand. The particular trade concerned, the nature of the stock, and the limitations of the business premises must determine the extent to which this ideal principle can be carried into practice.

The tarnishing of stock constitutes, in some trades, a considerable burden on the business. It arises from several causes as, for instance, the natural dampness of the premises, which will make iron and steel articles rust, brass goods become black and many fabrics rot; the too long exposure to the sun, which will spoil dyed dress stuffs, chocolate, confectionery, and many other articles of merchandise; and even the mere action of light, which will perish india-rubber. How the dead charge for loss by shop-soiling may be reduced depends entirely upon the nature of the trade. No royal receipt can be given for it. Constant vigilance and forethought must be brought to bear in attempts to keep down this charge, and, so far as concerns the general principles of the question, that is as much as can be said. Several of the cautions applying to particular departments of trade will be set down as we consider the various trades themselves.

Elasticity in Stock-keeping. In most trades there are times of the year when stock is heavy, and other periods when thin shelves are the aim of the careful buyer and stock-keeper. Particularly in those trades subject to great variation in the quantity of stock, attempts should be made to obviate the evil effects of the extremes. If accommodation be arranged on the lower basis, the periods of heavy stocks bring confusion. The shelves, bins, drawers, or other receptacles, cannot expand, and odd corners must be found for surplus stock away from goods of the same class. At the other extreme the only objection is from the point of appearance. Thin shelves have a poverty-stricken aspect that repels a customer. Even if the stock is, perforce, thin through straitened funds, it is well to disguise the fact. "Assume a virtue, if you have it not" is often a legitimate piece of counsel, and obedience to the precept a proper proceeding. The accommodation for stock should be framed on the larger scale. One may get a small boy into a man's garments, but the man cannot hide himself in the boy's clothes. *Elasticity* in any system of stock-keeping is something which should be sought. There are several means to its attainment, although every man, in applying the principle to his own needs, must be the judge of the individual factors requiring consideration.

Shop-fitting. Let us take the business of a Gentleman's Outfitter as typical. A selection of stock boxes or drawers filling the shelves is the most convenient system of stocking. It is never apparent whether the boxes are full or empty, so that the thinness of the stock is never evident when it is low, and if the boxes or drawers are numerous enough for full stocks we have elasticity to its ideal extent. The accessibility of stock, upon which we have already laid stress, is another feature of such a scheme. There are numerous other trades to which the same principle may be applied, though usually in a less degree. The draper, for instance, the ironmonger, the bootmaker, and many other shopkeepers, are modifying the shelf-arrangement by the replacement of parcels by stock boxes or drawers, and the benefits of the improvement redound upon both the purchaser and the merchant. More rapid attention may be given, a smaller number of counter salesmen is adequate, and the stock is better kept.

Selling. Among the qualifications which go to make a successful merchant that of selling is the chief. The functions of buying and of stock-keeping, however excellent in their systems and conduct, are barren of profitable result unless they are rendered complete by a successful selling department. It is easy to buy, but even if the right goods be bought at the right prices, an insufficient selling organisation will rob the buyer and the stock-keeper of the proper fruits of their labour.

Naturally every merchant desires to obtain as high prices as possible for the merchandise he handles without unduly curtailing sales. He strives to do as large a trade as he can without inviting custom by sacrificing his legitimate profit and surrendering the principles which should guide him in determining his prices.

There is greater danger in selling too cheaply than in framing prices on too high a scale. Young merchants and young firms are too often prone to "slaughter" prices, to the annoyance and loss of the competitors whose custom they are trying to alienate, and often to their own ultimate undoing. There is a limit of cheapness below which business is not worth having, and every merchant should find out where this limit is in his own case.

He should be able to tell exactly what are his *working expenses* or *dead charges*. If he buys an article at 20*s*. and sells it at 20*s*. he has not only not made a profit—he has incurred a loss. It should be an invariable rule in business that every sale should represent in profit not less than its proper proportion of working expenses. Working expenses vary in different trades. In a large grocery business they may equal only 5 per cent. of the turnover. In a small chemist's business they may be 50 per cent. And here we may consider what are working expenses.

Working Expenses. We must draw a clear line between the cost of goods and the working expenses. The former includes the money paid for the goods, the cost of carriage and of packages, and loss by deterioration. Many merchants consider as cost price only the money actually paid for merchandise, reckoning the items of carriage and deterioration loss as working expenses. This is wrong. Merchandise is often purchased carriage paid to warehouse, and other goods are bought carriage forward, the amount of carriage depending upon the nature of the goods, the classification under which they come in the Railway Companies' regulations, and the distance they are transported. To act upon the principle that this charge is a working expense is to assess twice over goods that have been purchased carriage paid, and to release from part of their proper share of the charges for transportation articles upon which carriage has been paid upon delivery. Carriage should invariably be reckoned in cost price, and for goods that are marked on the shelves or in the drawers, the carriage should be included in the cost price marked upon them and the selling price arranged with this as a basis.

Apportioning the Cost. Assume that a clothier receives a consignment of cloth, the invoice price of which is £50, and that the carriage has cost him £2. Assume, again, that the price of the cloth per yard is 4*s*. 2*d*. It has cost 2*d*. to bring each yard in the rolls of cloth to his shop, and the cloth ought to be marked as having cost 4*s*. 4*d*. per yard. The ideal system of apportioning carriage-cost should also take into consideration differences of bulk and weight in individual articles. Where the package of goods received is so mixed up the system of adding the absolutely correct proportion of carriage charge becomes impracticable. Some of the articles may be bulkier or heavier in relation to value than others and ought, therefore, to be made to carry a

larger share of the transportation charge. But to work out the proper proportion to its correct mathematical value is not possible, and it is well to treat the contents of one consignment as if the differences mentioned did not exist, and to assess each article upon the carriage expense in regard to its money value to the whole package.

We have mentioned loss by deterioration as a charge which should be reckoned in costing. This depends upon the particular trade. Where the loss by perishing, tarnishing, or going out of fashion is fairly uniform over the whole stock, it may be reckoned as a working expense. As typical of the justice of treating deterioration as part of cost price, we may instance the strawberries and other fresh fruit sometimes sold by grocers. Should a stock of this fruit be left on hand on Saturday night, it will probably be unsaleable on Monday morning. It would not be just to spread this loss over all the groceries sold. The fruit should be sold at such a price as will, after paying for the loss by perishing, leave a profit on the whole quantity of fruit sold.

Working Expenses Defined. Working expenses may be defined as the cost of running a business. They include wages of salesmen and other *employés*, rent, taxes, light, heat, paper, string, office expenses, bad debts, postages, advertising, interest on capital, and salaries of principal or partners. These last two items—interest on capital and salaries to owners—are frequently omitted from the reckoning of working expenses by private traders, but they should always be included. The money invested would, if invested elsewhere, have earned money, and the service rendered by principals in a business should also be remunerated apart from the interest upon capital.

If the business be one in which the working expenses amount to 20 per cent. of the turnover, the cost price of any article should be increased by 25 per cent. to ascertain the gross cost price—*i.e.*, total cost, including working expenses. There is frequently disaster in business from the practice of reckoning percentages upon cost at the same rates as percentages on receipts. It may be argued that the term profit correctly means profit on cost, but danger lurks in adopting cost as the basis in practice. Expenses are calculated on turnover, and the difference between a given percentage on cost and the same percentage on turnover should be clearly recognised and allowed for.

In some trades a considerable business is done in articles which are not put into stock, but are merely ordered from the manufacturers direct for customers, or sent direct to purchasers whenever they reach the merchant. These do not build up the working expenses as ordinary stock does, and it is reasonably considered that they may be sold even if the prices received for them do not represent in added profit the average proportion of working-expense charge. This practice is permissible, but it should not be indulged in except when necessity demands. In any case it must not be forgotten that the sale of such articles without the addition of the full proportions of working expenses raises the working-expense charge, which should be added to goods sold from stock in the regular way.

Selling Methods. The shopkeeper who would make his way to success must impress and attract the public, and the methods by which this is attempted are as diverse as human ingenuity can suggest. In the window of a shopkeeper in a London suburb there is prominently displayed this legend—"No order too small for our attention, none too large for our execution." This is calculated to impress the stranger, and, if the shopkeeper who exhibits it is as systematic and enterprising as the sign would lead one to suppose, his success is not a matter of doubt. The announcement is much more than merely a catchy advertisement. It expresses in thirteen words the fundamental principle of business success. The man who is "superior" to attention to small things is frequently surprised to discover that he is considered too small for big things.

The methods devised for attracting strangers to the counter include shop and window displays, price-cutting, the marking of all goods with plain figures, periodical sales, catch penny lines, press advertising, and circular distribution. Some of these subjects are so large in themselves as to deserve special treatment. Shop and window displays and advertising will be discussed at length later. The other matters we may deal with in a few words here.

Price-cutting. The practice of price cutting has become so general and so vexatious that shopkeepers have rebelled. No trade is sufficiently united to suppress it, but action in attempts to overcome the evil has been manifested in two ways. The first is *substitution*. The cutting of prices is practised chiefly in widely advertised articles of large sale—patent medicines, for instance. Substitutes as nearly as possible resembling the advertised articles are manufactured and sold instead of them whenever possible. The merchant cannot be blamed for attempting to provide substitutes provided that there is no deception practised and that the customer knows what he is buying. Both the public and the manufacturer are rather given to consider the retail trade as a philanthropic institution established for their benefit and not to yield livelihoods to its members. The other result of price-cutting is the spread of the principle of *price maintenance*. This means that manufacturers sell their specialities only on condition that a minimum selling price be maintained by distributors. Naturally, merchants encourage manufacturers to adopt price maintenance, and would be foolish in their own interests if they did not sell price-maintained articles in place of those in which there is unbridled license to cut prices.

Price-cutting is scarcely defensible. Whether it be a magazine or a box of pills, the retailer deserves his profit for the part he has played in acting as intermediary between the manufacturer and the public. Retailers suffer from cutting and retailers only are responsible for it. Unfortunately, it is the irresponsible members of the merchant class who have given the practice its strong hold.

THE PLACE AND INFLUENCE OF ART IN LIFE

By P. G. Konody and Haldane Macfall

THERE is no entirely satisfactory definition of the nature of Art. Philosophers, writers on æsthetics, and art historians have tried times without number to confine its functions within narrow limits, or to express with scientific precision the essence of art in a simple phrase. Others, like Count Tolstoi, have devoted whole volumes to the question, "What is Art?" without arriving at a satisfactory conclusion.

The most widely-spread fallacies are, that art is exclusively concerned with beauty, and that it is necessarily a transcript of Nature. It is, in fact, a language for expressing human emotions, but this definition does not completely cover the ground. The creation of a true work of art entails a state of exaltation, a pleasurable thrill, in its originator—a thrill which is communicated to the beholder and produces an equally pleasurable sensation that raises his mind into spheres far beyond the matter-of-fact details of everyday life. The function of Art is, therefore, to introduce pleasure into the life of everybody, and a knowledge and appreciation of Art is necessary for the complete enjoyment of life. The more the student advances in this knowledge, the more intense will be his enjoyment.

The Language of Emotion True, much that, whilst he was in ignorance, left him unmoved, much even that he liked, will commence to jar on him; but there is ample compensation in the thrill, the incomparable delight, that results from the appreciation of true art. Thus the untrained ear may derive pleasure from the tunes of a barrel-organ. Musical education will turn this pleasure into veritable pain, but the enjoyment of a complex orchestral symphony is so immeasurably increased, that musical education becomes a very distinct advantage. The loss of enjoyment is only in quantity, the great gain in intensity. The same may be said with equal justice of painting, sculpture, poetry, or any other method of artistic expression.

If Art is defined as a language for expressing emotions, it must be borne in mind that at its best it is a vague language, a language which suggests far more than it actually says, and in consequence stimulates independent thought. Hence its educational influence. It helps us even to appreciate the beauties of Nature, and here, again, increases our powers of enjoyment. Even things ugly in themselves are glorified by the painter's emotion and selective power, and he can teach us to regard them from his point of view. And the increased appreciation of Nature reacts again upon our attitude towards the work of Art.

Art and Human Progress. It is unnecessary to enlarge upon the part played by Art in human progress. It has always had a refining influence, and it is almost impossible to imagine any great civilisation that does not tally with an equally great advance in Art. At a time when the knowledge of letters was practically confined to monks and a very small minority of students, the painted picture and the carved relief had to serve as educational instruments. The great religious truths, as well as history, were taught to the ignorant masses through the direct appeal to the eye of works of Art.

The exercise of Art is of an essentially social character. In the dark ages of the prehistoric past man made his implements for a distinctly useful, personal purpose. He embellished them by the introduction of Art in a primitive form, to please or to impress his fellow men. Thus,

Art has always been of a more abstract and ideal character than the more utilitarian pursuits of humanity, and has played an enormously important function in the development of social life and human culture.

The artist's life, compared with that of the professional man, is and must be a precarious one. But if the youth decides, with the recklessness which is the splendid courage of youth, to be an artist, who shall turn his eyes from the vision? At least, he sets foot on a career where rich men and poor start with equal chances and no favour. But if he would realise the best that is in him (and by no other means can he achieve distinction), let him at the very start set his goal before him; let his goal be high; and let him move every step of his career towards it. Let him, above all, not stumble along towards vague ends. It is necessary to have, at the very beginning, a firm grasp of what Art is; only then can we discover and practise the simplest way to create it.

The Human Need of Art. The common mind thinks of a work of art always as a picture, painted in oils, and framed in gilt. But Art is not a handsome toy for the rich to play with; it is a far wider and deeper thing than that. Art is almost as great a human need as Speech. Why the term artist has come to be associated with painting in particular it is difficult to say, since a painter is not in any way a greater creator of Art than is a sculptor or a musician, or a poet, or an architect. We have here to do with the Art which moves us through our sight, the art of painting, sculpture, architecture, and the crafts.

Whatever be his religion or his philosophy, the most interesting thing to Man is Life. The desire to know all he can know of Life is the beginning and the end of all his questionings, of all his acts, of all his adventures, of all his hopes and fears and sins—nay, beyond the very grave his eyes are fixed on everlasting Life.

The Necessity for Clearness. There are two ways in which we may know about Life. We know it by living it ourselves; we know *of* it through the experiences of others. Now it is clear that even though we should go through the most romantic and adventurous career, like a Cæsar, a Columbus, or a Napoleon, we shall not know even then, in our own selves, a hundredth part of life as it is. We can know what the rest of the world knows and feels only through some means by which men can communicate sensations; and just as the great thinker conveys his thought through language, so the artist conveys his emotions through Art. Art, then, is the means by which we transfer emotion to others.

Now, it is not enough to utter a thought to account it Speech; in order to give it forth to our fellows we must put it into such clear language as they will understand. Nor is it enough to create an emotion to account it Art; we must state it in a way that will arouse response in others, whether by the

THE MAJESTIC USE OF LINE IN ART

"Alessandro del Borro," by Velasquez, showing the use of line to give a sense of dignity

use of words in prose or verse when we call the art Poetry, or by sounds when we call it Music, or by colour when we call it Painting. Art is the language of the emotions, the vehicle by which we transfer an emotion to others, so that they feel it as we have felt it. Thus, by Art we can be made to feel fear or love or pity or hate even if we have never been brought into personal touch with some of these human sensations. When Dickens takes us through the meadows, and we walk with Little Nell, entering into the child's heart and feeling akin with her, we are experiencing real emotion conveyed by Art.

The Use of Colour. As, in music, certain sounds produce melancholy and others pleasure, so in Art we use gay colouring to give a sensation of gaiety, sombre colours to give solemnity, and so on. We can use these colours in majestic lines to give a sense of dignity, or we can use them in a demeaning way to give a sense of littleness. And thus, by using colours in their most proper way, to fit the idea we wish to express, and by using them in their most telling forms, we can paint on a canvas so that others, looking at the painting, can be made to feel the awe of a thunderstorm, the pathos of tears, the joy of the hunting-field, or the subtlest sense of the haunting sadness that lurks in the twilight.

Now, if the student has grasped the truth that Art is the Emotional Statement of Life, it will save him from two serious mistakes about which he must be very clear: Art is not Imitation but Interpretation; and there is a vast but subtle difference between Art and Craft.

We are all aware that the common mind thinks always of a work of art as being an attempt to paint things in an exact imitation, so that details in the painting "look almost as if you could pick them up."

Difference Between Art and Craft. But this realism has really little to do with Art; a photograph may do as much. It is neither for nor against its Art that the imitation should be so perfect as to deceive the eye; the artist's only concern should be that he so paints the object as to convey the general sensation that the object gave him, and the student will find early in his experience, for instance, that very often this detail and care spoil the general sense of his picture to a strange and uncanny degree, and that he has fogged the whole scheme in order to be true in little things which, at the end, have an untrue relation to each other and to the general idea. He has tried to imitate a thing instead of suggesting an impression of it.

It is important to be clear as to the difference between Art and Craft. We have seen that, as Speech is the statement of our Thoughts, Art is the statement of the Emotions. We have seen also that it is not enough to have uttered a thought to account it Speech; it is vital that the thought should be so perfectly uttered as to arouse a responsive thought in the listener.

Hanfstaengl

THE BELITTLING USE OF LINE IN ART

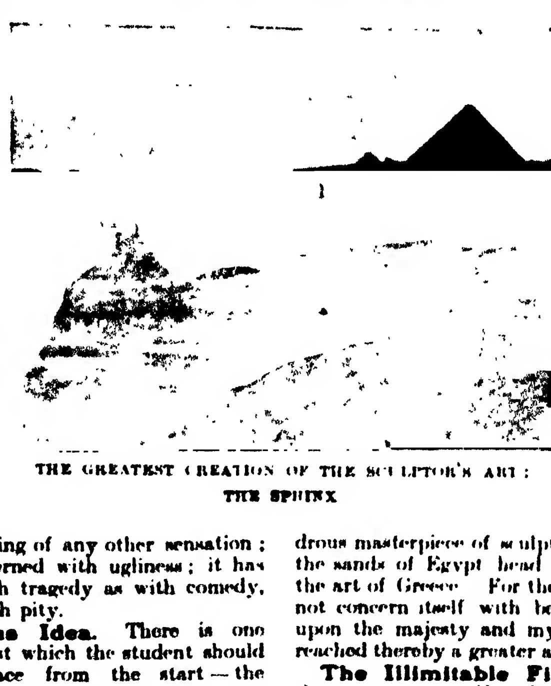
"Peasants at an Inn," by A. van Ostade, showing line used in a demeaning way, to give a sense of littleness

Otherwise we are but in a tower of Babel. And in the same way it is not enough to have uttered an emotion to account it Art; it is vital that the emotion should be so uttered as to arouse a responsive emotion in the onlooker. And, just as thought is the more easily understood the more simply it is expressed, so the emotion most simply expressed is the most likely to have its effect.

Mastery over Tools. This perfection, or beauty of handling, by which Art is expressed, we call Craftsmanship. It must be abundantly clear that the greater mastery the student acquires over the tools of his craft the more easily and the more beautifully will he be able to express the emotions, whereby he will create a work of art. Still, he must never forget that this beauty of handling, which is craftsmanship, is not anything else but craftsmanship, and has not produced Art of itself. Art *must* create; it must transfer the impression of a sensation or an emotion to others. A woman may be very beautiful; she is not Art. Beauty is not Art, nor Art beauty. But a painter may paint a beautiful woman so that her picture affects us emotionally with the same sense of charm as the woman herself; then his painting is a work of art. Craft, let us understand, is that beauty of treatment which creates a work of art, but Art itself is not necessarily the creating of the sense of beauty any more than the creating of any other sensation; it is as much concerned with ugliness; it has as much to do with tragedy as with comedy, with laughter as with pity.

A Mischievous Idea. There is one great blunder against which the student should sternly set his face from the start — the widespread and mischievous idea that Art is a luxury and only for the rich, that the rich and the elaborately educated have some peculiar understanding of Art that is denied to the ordinary person. Art is not a luxury; it is a need of the human being, and only in proportion as Art is simple and large and widespread in its appeal can it be great and far-reaching. Let us take the art of words, and the best known example of it in the world. The parables of Jesus are among the noblest works of art—their appeal comes to the prince and the peasant—nay, to the very child. We are swayed, indeed, a dozen times in the day by our emotions and instincts, as against a single act springing from our reason. The power of Art is prodigious compared with the power of reason. Let us take another example from the art of words. If a writer conveys to the world a thought, such as that "sailors and fishermen, being by their calling in near relation to the powers and mysteries of Nature, are impressed with the works of the Creator," he gives utterance to a plain fact which leaves the world cold, and is narrow in its appeal compared with the statement of the same fact stated in a picture which reaches us through the emotions in the beautiful passage: "They that go down to the sea in ships, that do business in great waters; these see the works of the Lord and His wonders in the deep." Here the solemn use of the words seems to conjure up into the senses, as at the stroke of a magician's wand, the mystery and fragrance of the sea and the seaman's calling.

The Province of Art. Schools and cliques have tried to narrow the province of Art; but the student must beware that the province of Art is as vast as life, whose servant she is. The Greeks set up beauty as the ultimate goal of Art; they really meant that the sole object of Art was to create beauty. In sculpture Greece carried this idea as far as human power could take it, yet whilst she created supreme beauty in the human form, splendid as was her achievement, she never reached to the majesty and the grandeur of the Sphinx, the wondrous masterpiece of sculpture which stands on the sands of Egypt head and shoulders above the art of Greece. For the genius of Egypt did not concern itself with beauty; it spent itself upon the majesty and mystery of life, and it reached thereby a greater and more majestic art.



THE GREATEST CREATION OF THE SCULPTOR'S ART: THE SPHINX

The Illimitable Field of Art. Art, then, concerns itself with the tears and ugliness and the greynesses of life as much as with laughter and beauty. There is no limit to human emotions; there is no limit, therefore, to Art. The higher and nobler and more sublime the emotions created by the artist, the higher and nobler and more sublime will be his art. Shakespeare sounded the wide gamut of the emotions, from the heroic ambitions of man to his most contemptible jealousies; he reached to the topmost heights of Art. What Shakespeare did in the art of words a painter may some day do in the art of colour. It is well for the student to search the schools and styles of painting for the beauty of craftsmanship whereby he may give

THE GREEK IDEAL OF BEAUTY: TWO EXAMPLES IN SCULPTURE

utterance to his art and bring cunning to his craft; but he must always remember that mere beauty of painting will not raise him to high achievement in art; it is only as he succeeds in setting on canvas the sensations Nature arouses in him in all her varying moods that he may hope for name and fame in the years to come.

No school of painters is wholly right; none wholly wrong. Art is no narrow garden to be fenced round with little hedges of style, but a vast realm of the imagination; and whether the artist attempt to give utterance to the great emotions that awake him to the majesty of life, or whether he is happier in the tender moods that arise like ghostly whispers amid the misty reaches of the river at twilight, when the factory wharf and dingy warehouse of the workaday world change into a way of fairy palaces in a mystic city; whether he be more delighted to give utterance to the heroic emotions or is more stirred by the beauty of women or the tender charm of childhood—he is an artist indeed who does any of these things exquisitely or well, so that when we look upon his work we are moved by the emotion he saw and felt, which he thrusts by his skill into our understanding.

Let the student take this most serious fact to heart. The schools are teeming with young men and with young women who have gone into them with a vague notion that at the end of three or four years they will emerge fully-fledged artists, just as our universities and hospitals turn out men equipped for the professions. The result is that for one man who becomes an artist a dozen sink in the flood of heart-breaking failures. The schools can give us training in the craftsmanship of Art, and they do it well though it is a nice question whether the student cannot learn as much by his unaided study. But whether he go through the schools or not he cannot be an artist until the day that he creates—until the day he shows us how he sees life through his own eyes. No tricks of thumb, no scraps from the old masters, will make him a master. He must have something to say that he can put into the sensitive vision of his fellow men.

To be continued

THE DRESSMAKER'S ACCESSORIES & MATERIALS

The Articles required for the Dressmaker's Complete Outfit. Materials and Quantities. Drafting Bodice, Sleeve and Collar

By AZELINE LEWIS

THE articles required for a dressmaker's outfit are:

SEWING COTTON. A good make is needed for machine and hand work. Nos 24, 30, 40, 50, and 60 will be required in black and white.

SILK. For ornamental stitching and machine work. This should be firm and good, and about 1½*d*. a reel is the price to give

TACKING COTTON AND TAPE MEASURE.

TAILOR'S CHALK. For marking seams.

TWIST. For buttonholes to match the material, for fixing bones and steels into position by fan-stitching, cross-stitching on bands, etc That sold on reels is good for buttonholes

NEEDLES. From 5 to 9 are useful numbers for all kinds of work connected with dressmaking. No. 4 "Betweens" for boning.

HOOKS AND EYES. These are required of various kinds and sizes for fastening fronts of bodices. Small mantle hooks are used for waistbands. These, like all other accessories, should be good, as those sold in cheap packets are almost invariably useless

HOOKS AND BARS. These are sometimes preferred to hooks and eyes, as the bars are easily put on. They should be buttonholed over with silk, so as not to show when the bodice is fastened

PLACKET FASTENERS. These are small spring fasteners for placket openings in various makes Small spring hooks and rings or silk loops are, however, preferred by many good dressmakers and tailors, as they are neater and less noticeable than the former.

PINS. Get good ones—short whites are the best. Steel pins or lillikins are required for velvet.

THIMBLE. Whatever this be made of it is necessary the indentations should not be too shallow, as if so the needle will be constantly slipping.

SCISSORS. Large for cutting out, and small sharp-pointed ones for buttonholes. A good pair of nail scissors will do for the latter purpose, if a punch be used for the hole.

ROLLER. For pressing seams and sleeves. A cricket bat, round stick, or rolling-pin, of ash or beech, will do for the purpose if covered.

SINGLE TRACING WHEEL. For marking out seams.

SKIRT BOARD. For tacking skirt lining and material together, pressing seams, etc.

FLAT-IRONS AND IRONING BLANKET, IRON-STAND AND HOLDER. For pressing generally.

SEWING-MACHINE. See Part I.

PUNCH OR STILETTO, for buttonholes. If buttonhole scissors are not used, one of these is necessary. For the punch have No. 5 point.

BELTINGS For the tight inside band of bodice, either single belting, webbing, or satin faced belting is used. For skirt bands, single or double Petersham, wide or narrow, shaped or straight, and satin faced belting may be used

LUTE RIBBON of various widths for lining waistband, neatening turnings, etc.

PRUSSIAN BINDING, OR GALOON. For bone casings, skirt loops, &c

WHALEBONE, BALEINETTE, FEATHERBONE, BONE, OR COVERED STEELS For stiffening seams of bodices, and so preventing wrinkles Whalebone and featherbone are somewhat expensive, but, of course, are the best, as they are more pliable and give to the figure, although the substitutes may be made to do good service if properly prepared Steels are much used, as they are easier to put in.

EDGE BONE This is very narrow, and is used for evening or laced bodices, and edge-to-edge fastenings.

SKIRT BINDING. There are many makes for this purpose, but braid, bias Velutina or brush binding are the most used The latter is perhaps the best, and it can be had in almost any colour It wears well, and dirt does not cling to it as to braid

BUCKLES. For the tight skirt bands, instead of hooks and eyes, if preferred Their use, however, is a matter of taste

A DRESS STAND A dress or bodice and skirt stand, while desirable in the case of the home worker, is quite necessary to a dressmaker's outfit. The expanding dress and bodice stands are the best for the latter, but are somewhat expensive The home worker, however, can make herself an efficient substitute for a bodice-stand out of a discarded bodice, or even a bodice lining which fits well. See that the seams are firmly stitched up, close fronts together securely after having removed all buttons or anything likely to make a ridge, sew a piece round neck opening, and proceed to stuff the inside thus made till it is firm and well filled A stick of the right length for the middle will make it stand better. Sew a piece of cloth or material firmly to the bottom and then close armhole. The sleeve can also be stuffed in the same way, and will be found useful and helpful as an arm-stand for ascertaining the length and fit of a sleeve, especially if gathered, puffed, or of the ornamental kind now so fashionable, and as sleeves alter so constantly, it is well to be prepared to meet the changes.

DRESS-PRESERVERS. These will also be needed, whilst a pinking outfit can be added, but, though useful, it is not an absolute necessity.

Materials. The materials of the dressmaker are so many that a full list is impossible, but the following is a fair average of the widths of those most in use:

Serge, Frieze, Cashmere, Voile, and double-width goods, 44 to 48 inches in width.

Fine-faced Cloth, 48 to 54 inches.

Fancy Flannels, Delaine and such-like goods, 27 inches.

Plain Silk, 22 inches.

Washing, or Pongee Silk, 27 to 36 inches.

Silk (very good makes), 42 inches.

Prints and Cotton goods, 27 inches.

Ordinary Satin, 22 inches, but some makes for mantles, etc., are double width.

Liberty Satin averages 48 to 50 inches.

Velveteen, 24 to 27 inches.

Velvet (ordinary for trimmings, etc.), 18 to 22 inches.

Linings. Linings should be good. It is not worth while making up a bodice on a poor foundation, as this stretches and loses its shape, and will never be satisfactory. In this section of dressmaking, however, as in materials, fashion has to be studied, and of late the special makes of sateen are largely used for both bodice and skirt linings. These are now known under various names, such as Roman Satin, etc.

The linings which are most commonly used, and which are recommended for wear, are:

BODICE LININGS.

For Serge materials: good Silesia, 36 inches.

For Print or Cotton: Calico or Silesia, do.

For Cloth: Sateen, 30 inches, or Italian Cloth, 54 inches.

For Muslin, Delaine: Sateen or Cambric.

For Silk or Satin: Silk is best to use, but the better makes of Sateen or fancy Sateen, if good, will do equally well. For light materials the light backs should be used, and for dark goods black or dark backs, according to the colour.

SKIRT LININGS.

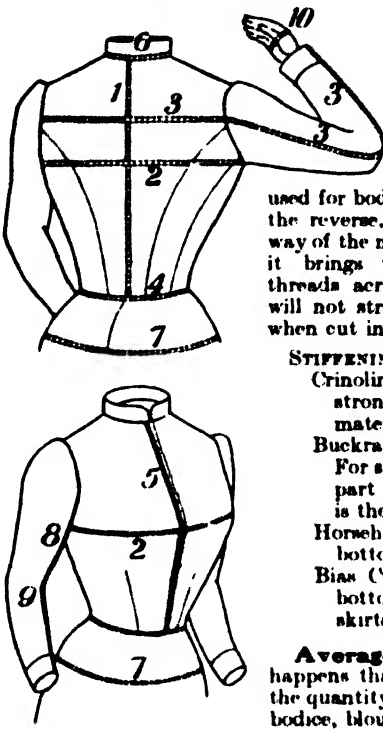
For Serge: Linenette, Sateen, or Alpaca.

For Velveteen: Alpaca, or silk-finished Linenette.

For Silk: Sateen, Silkette, or any other corresponding make.

For Cloth: Italian Cloth.

The question of skirt lining is, of course, one that is answered more or less by Dame Fashion. Sometimes the skirts are lined throughout; then, again, she decrees that they shall be made on a separate foundation, secured to the skirt at waist. For transparent materials, voile, and such-like goods, the latter is by far the most effective. Cloth and other materials may be unlined, but in the latter case many tailors and dressmakers prefer to line the front width. Some materials, like silks and good woollens, should be cut somewhat larger than the lining, as they shrink slightly when cut. Ordinary sateen, if used for bodice lining, should be cut the reverse, and not the selvedge way of the material, as by so cutting it brings the selvedge or warp threads across the pattern, and it will not stretch quite so much as when cut in the usual way.



19. BODICE MEASUREMENTS

STIFFENING MATERIALS.

Crinoline Muslin: A coarse, strong muslin for washing materials.

Buckram and Tailor's Canvas: For stiffening collars and cuff part of sleeves. The latter is the most used.

Horsehair Cloth: For skirt bottoms.

Bias Crinolette: For stiffening bottoms of dress and underskirts according to fashion.

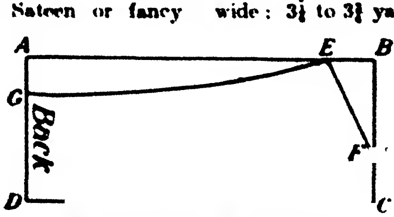
Average Quantities. It often happens that a dressmaker is asked the quantity required for a costume, bodice, blouse, etc., and the following list of quantities required for the *plainer* garments may be found useful to the beginner:

For a plain dress of print, 27 inches wide: 10 yards.

Cashmere and double-width goods: 6 yards.

30 and 36 inch material: 9 yards.

For a plain walking skirt of material 44 inches wide: 3¼ to 3¾ yards.



20. COLLAR MEASUREMENTS

Circular skirts, 48-inch goods: 3 yards.

Pleated skirts, 3½ to 4 yards.

Bodice with basque, medium size: 2 to 2¼ yards of double width material.

Bodice without basque: 1¾ yards.

Bodice lining, 36 inches wide: 1½ to 2 yards.

Plain shirt-blouse, 27-inch material: 3 yards.

Blouse with full sleeves, 22 or 27 inches wide material: 3½ to 4 yards.

Gathered with full do., do.: 4 to 5 yards.

Eton coat, do.: 1½ yards.

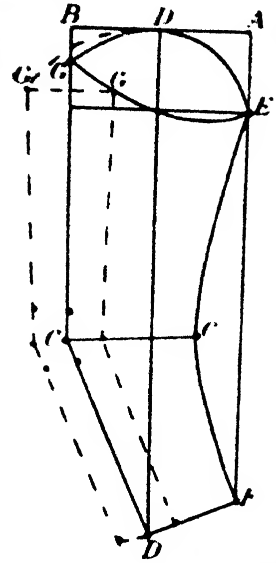
Russian blouse, or coatee, do.: 2¾ yards.

NOTE. Materials with an up and down,

either of pile or pattern, cannot be used as economically as those without, as the pattern cannot be reversed, and each piece must be the right way up of the material. In the case of velvet or velveteen even more must be allowed, as each piece must be cut separately. This last, however, is fully shown in a later diagram.

FRILLS AND FLOUNCES will add to the quantities given above for skirts, these depending on the number, style, and width of same.

For Kilting about three times the width of skirt is usually allowed, and as this is cut on the straight, the necessary addition is easily arrived at in this way. If a four-inch wide kilt is to be the ornamentation, there would be nine strips to the yard, giving about 10½ yards for kilting, and the width of the skirt will decide whether this is too much or too little.



21 DRAFTING THE SLEEVE

Gathered Frills are a little more difficult of calculation, as these are cut on the cross, but 27 inch goods will give a crossway strip of about one yard across the full width. The corners, however, can all be used, but the shorter lengths should be joined in with the longer ones, so as to avoid many seams coming together.

For Crossway Frills one and a half to twice the width of the skirt is usually allowed. The quantity, however, depends very much on the material used, and for thin or flimsy stuff even more may be allowed.

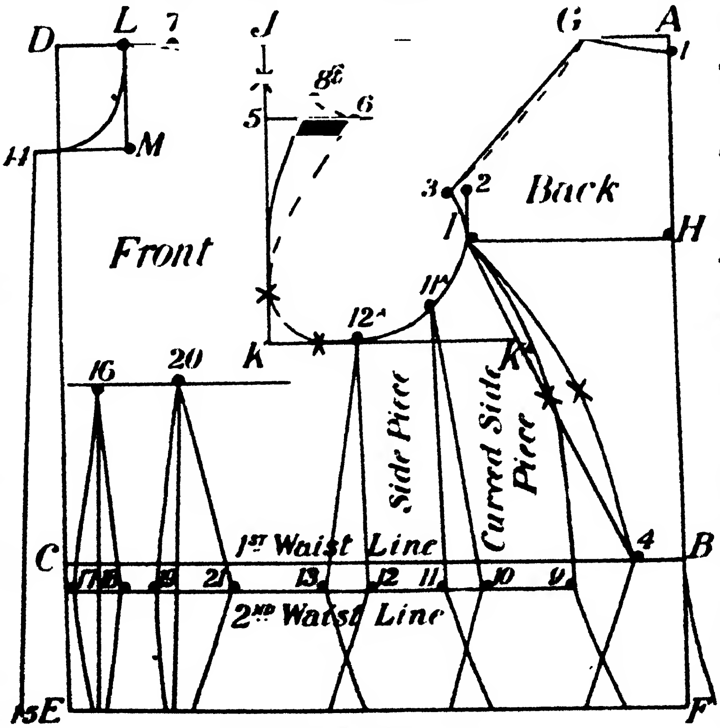
For Box Pleating, about three times, and for Double Box Pleating, four times the width of skirt is the usual allowance.

The Balayeuse, or silk frill, is generally cut on the cross and gathered. If straight it is kilted, the edges being pinked in either case. If kilted, it is cut on the straight of the material, the make of the latter deciding whether it should be cut selvedge ways or across, but it usually wears out quicker if cut the former way. About two yards of silk will make a crossway frill five inches wide for a skirt three and a half to four yards round. In this every little bit of the silk can be used.

When all the pieces are joined, unite the whole in a circle, being careful it is not twisted and that all seams are on the wrong side. Press them, fold in four, and tack the four thicknesses together. See that all the edges are perfectly even, cutting off unevennesses; it can then be pinked at a charge of about 1d. for three yards. Undertakers usually do this, but it can be done at home with the necessary tools.

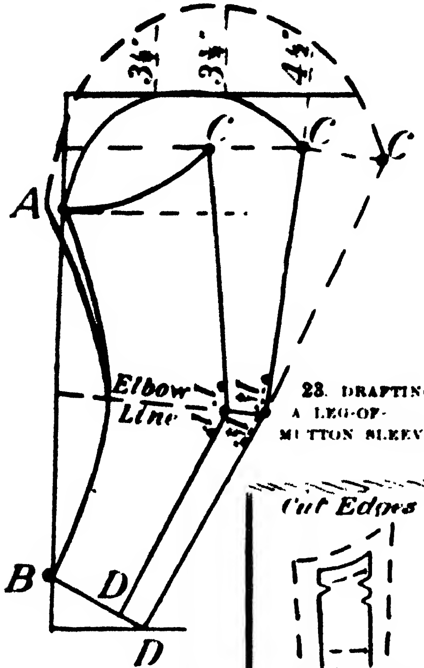
Drafting of Bodice, Sleeve, and Collar. It is so easy nowadays to buy a pattern of any size, or to get one cut, that many know nothing whatever about drafting one from measurements, but the ability to do so is almost essential to anyone aspiring to a proper knowledge of dressmaking.

There are many systems of bodice drafting, but the following is adapted from a French one, which we have found to answer perfectly, both in cut and fit, with



22. DRAFTING THE BODICE

the additional advantage of being easy to understand. It is based on the following proportional divisions of *half* the bust measure-



23. DRAFTING A LEG-OF-MUTTON SLEEVE

ment, viz.: *half*, *one-third*, *two-thirds*, *one sixth*, and *one-twelfth*, the others being needed to obtain correctness of outline and fit.

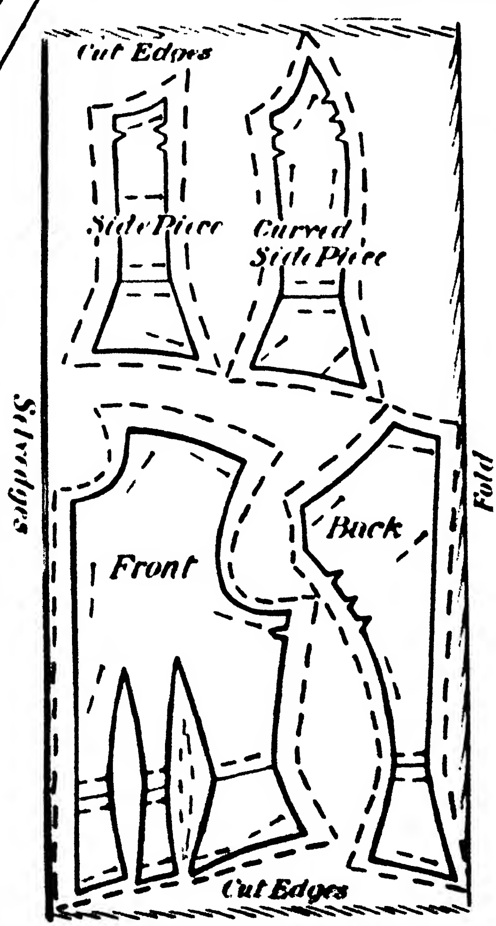
Very few figures, however, are absolutely symmetrical, the Juno-like type existing more often in the halls of statuary, or in an artist's imagination than in real life; but the deviations from the above proportions of the measurements, which in most cases should be very slight, are easily ascertained and arranged for In this shape the back edge of the second dart comes more or less on the cross, the difference being clearly seen in diagram 26. [See also TAILORING.]

A good dressmaker, however, whether amateur or professional, should study well the figure she has to deal with, so as to note any peculiarities which may assist her in drafting and cutting out a bodice, either from measurement or from a pattern, and so do much towards obtaining that desire of a modiste, "a perfect fit."

The Measurements. For this system the following are needed:

1. Length of Back.
2. Bust measure.
3. Width of Back, continuing measure to elbow, thence to wrist (the two last are for sleeve).
4. Size of Waist.
5. Length of Front to Waist, also marking Bust line.
6. Neck measurement.
7. Hip measurement.
8. Length of Front Seam of Sleeve.
9. Size of Elbow.
10. Size of Hand (closed).

The two first may be called the primary or essential measurements, as within the rectangle formed by them the bodice is drafted.



24. CUTTING OUT THE LINING

Take these measures, as shown in the accompanying diagram [19]. No. 2 should be taken rather loosely, No. 4 closely. No. 6 should be easy. To get the waist-line, fix a tape (or a second measure) securely round the waist, when it will fall naturally into the proper line, and will thus give a definite measure for Nos. 1 and 5, which are both very important, and the average eye is not reliable enough to be trusted for the purpose.

Before proceeding with the drafting, have the measurements clearly written out for reference, also the various divisions of the bust measure under consideration.

The bodice in the diagram [19] was drafted to an 18-inch measurement, the necessary divisions of which for drafting and explanatory purposes are — $\frac{1}{2}$ = 9 inches; $\frac{1}{3}$ = 6 inches; $\frac{2}{3}$ = 12 inches; $\frac{1}{6}$ = 3 inches; and $\frac{1}{12}$ = $1\frac{1}{2}$ inches.

Remember only *half* the bust measure is used, as only half the bodice is drafted. The above would, therefore, mean a 36-inch full bust

measure. Half the waist and neck measures also would be used, but the full length of back must be taken, as will readily be understood.

The Drafting. In the following drafting the proportional lines are marked in their alphabetical sequence; those for the shaping of the bodice are numbered in the order in which they should be taken and drawn [22].

Lines *A-B* and *C-D* are formed by length of back, plus half an inch for neck curve of back.

A-D and *B-C* are each half bust measure.

B-F and *C-E*: Length of basque.

The length of the last lines depends entirely on taste and fashion.

B-C: Waist line.

A-H and *H-I* are each $\frac{1}{8}$ of bust measure.

A-J, $\frac{3}{8}$ of do.

J-K, $\frac{1}{8}$ of do.

L-M, $\frac{1}{8}$ of do.

The last, however, should not be drawn till the front shoulder is done, as it is determined by the position of this.

A-G, $\frac{1}{6}$ of bust measure, less $\frac{1}{4}$ an inch to allow for curve.

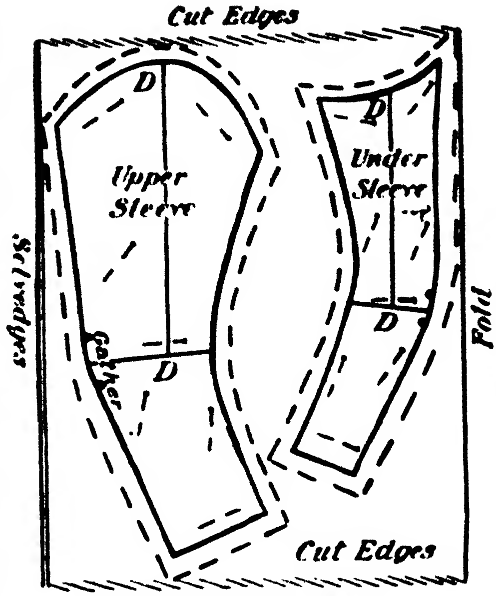
A-1 is $\frac{1}{2}$ an inch.

H to *I*: Width of back ($\frac{1}{8}$ of bust measure).

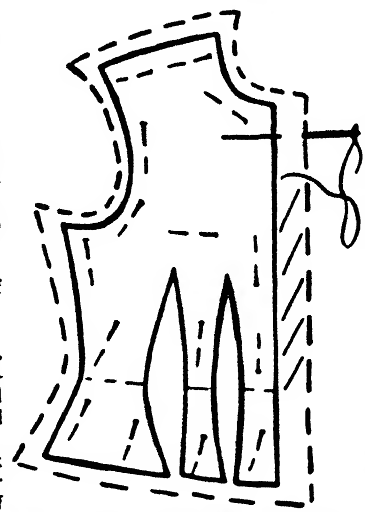
I-2 is $1\frac{1}{2}$ inch.

This measure, however, varies, according to the dictates of fashion with regard to long or high-shouldered effects.

2-3 is $\frac{1}{2}$ an inch; draw back curve, then from 3-*G* for shoulder (hollow this out $\frac{1}{4}$ of an inch afterwards, as shown by the broken line).



25. CUTTING THE SLEEVE



26. BASTING LINING AND MATERIAL TOGETHER

B-4 is $1\frac{1}{2}$ inch; mark this and draw *I-4*. Measure 1 inch in centre of this to the right (to assist in drawing back curve). Draw back from *I-4*, curving through mark just made in centre, as indicated by the cross.

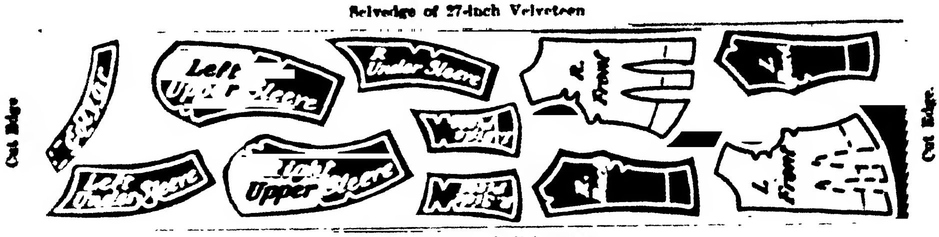
Front Shoulder and Armhole. *J-5* is $\frac{3}{4}$ of an inch longer than *I-2*, the exact centre being marked by a X; 5-6 is drawn at right angles to give the shoulder-line of front. Draw 6-7 $\frac{1}{4}$ of an inch less than 3-*G*, placing the centre on the mark in that of *J-7*.

The front shoulder-line should always be less than the back, as it must be stretched to this; in some cases it can be $\frac{1}{2}$ of an inch less than back.

At angle formed by *K* and *K*^{a}, mark $\frac{1}{16}$ of bust measure (this is merely to assist in obtaining armhole curve). Form armhole from 6-3, passing through marks made in angle *K* and *K*^{a}, rounding well as it approaches back curve so as to continue this.

4-9 is 2 inches, the amount to be suppressed at waist between back and side body. Mark this on first waist-line, then curve from *I-9*, taking it $\frac{1}{4}$ of an inch to right of line *I-4*, and pass through this opposite the centre marked by a X. (The curve at upper part thus given will allow room for shoulder blade, and enable the side-piece to fit easily and to set closely at the armhole.)

Selvedge of 27-inch Velveteen



Selvedge of 27-inch Velveteen

27. CUTTING OUT BODICE AND SLEEVES

Now advance front shoulder from 6-8 and 7-[illegible] of bust measure in each case; round this slightly, and draw front portion of armhole from 6 to line *J—K* as indicated by a firm and not a broken line.

This advance of shoulder-line gives the requisite pitch forward to throw the back dart on the cross.

From *L* draw *M* (1/4 of bust measure), and from this draw another line at right angles to meet line *D–C*. In the rectangle thus formed draw front neck.

The Side Pieces. To obtain 2nd waist-line, lower 9 3/4 of an inch below *B–C*, measure length of front, from neck mark this, also bust line; on line *D–C* draw real waist-line from 9 to length of front just marked.

This lowering of waist line is to allow for the inch taken out in back curve, and to bring it up to waist line of this.

On this 2nd waist line mark 9-10, 11-12; and 13 for side-pieces. 9 10 may vary from 2 1/2 to 4 inches, according to size of waist; in the case of larger sizes, however, it is better to have three smaller side pieces than two very large ones. [See Large Size Bodice.] 11-12 should always measure 1/2 an inch less than 9 10, 10-11 and 12 13 each measure 1 inch for waist suppression. Draw 11 11[a] and 12 12[a] before 10 11[a] and 13. The reason for this is that the under arm piece should be straight, and it is easier to get the right inclination of the other lines by so doing.

Front-fitting Line and Darts. Measure neck and bust, and add on in front the amount taken in side pieces and back (usually from 1 to 1 1/2 inches), and draw 14-15 for front fitting line. Be careful not to "bow" this out at the bust, nor make it tight. For the darts, measure from *B* 4, *9-10, 11 12,* and *13-C*, subtract half the waist measure (remember, only half the measures are used) from this, when the remainder will have to be suppressed in the darts. Mark 16, which may vary from 2 to 2 1/2 inches from front fitting line, draw line for centre, then mark 17 and 18 at equal distances on either side and draw these lines. (From 1 to 1 1/2 inches is the average amount to be taken in this dart, which is always the smaller of the two.)

For back dart mark 19 1 inch to right of 18, then 20 on bust line, which may be from 1 1/2 to 2 1/2 inches from top of front dart. Measure and mark off amount to be taken in back dart on waist line, and draw 20-21. (Remember, in this cut of bodice the front edge of back dart should be nearly straight, and the back edge almost, if not quite, on the cross.) The back dart also is always the higher of the two.

Now divide and add on the superfluous inches of hip measure equally on the various basque portions, and draw these as sketched.

Lastly, go over the measurements carefully, compare them all with those taken, and make any alterations necessary before tracing and cutting out.

The under-arm piece may be traced out separately, to avoid cutting off the basques of front and curved side-piece, or if not, piece must be joined on exactly the same as those cut off.

NOTE: If the worker be familiar with the French metre, she can use this for this system counting by centimetres instead of inches.

The Collar [20].

A–B; *C* and *D* are formed by size of neck at lower part.

A–D and *B–C* each measure 3 inches.

A–E, size of neck for top of collar.

G–D, 2 inches.

E–F the same.

The depth of collar, however, varies with the length of neck.

The Sleeve. Line *A–B* is 1/2 of bust measure less 1/2 of an inch (this will be taken up by the curve) [21].

B–C is length of sleeve, from width of back to elbow [see diagram 19].

D–D, midway between *A–B*, is entire length of sleeve.

A–E is 4 inches, *B–G* 1 1/2 inches.

E–F, length of front seam.

C–C, size of elbow.

The above drafting gives a plain coat sleeve, which is the foundation of all other sleeves, and from which any kind of shape can be evolved. The under-sleeve can be any size desired, provided the amount taken from this be added to the upper sleeve, or in proportion as fulness may be required at the shoulder part. This is indicated by the broken lines, whilst the next diagram [23] shows the evolution of a "gigot," or leg of mutton sleeve, from the last shape indicated.

Making the Bodice. Having thus reviewed the preliminaries, the stitches, the *materials, and their uses, the method of obtaining a pattern from measurement,* we will now turn to the more interesting side, that of dressmaking pure and simple. We have chosen a dressmaker's bodice to begin with, rather than a blouse, because it may be described as the basis of a sartorial education.

Cutting Out the Lining. Before placing the pattern in position, press out all creases in the lining with a warm iron. Now arrange the various portions of the bodice pattern just drafted and cut out to the best advantage on the lining, which should be double [24]. Allow for the turnings 1 inch on the shoulders and under arm seams, and from 1/2 to 3/4 of an inch on all others for alterations. Curve the neck and shoulder outwards to allow of possible alterations here. The front fitting line must be placed 1 1/2 inches from the selvedge and even with this. Place all waist lines, except those of front, on the straight of the material, then pin the pattern to lining. Trace the waist lines carefully, also the bust line, front fitting line, darts and inset mark. Keep the lining and drafting quite smooth, then trace all round the outline of the pattern with a backward and forward movement. Remove pattern and pin together before cutting out to prevent slipping.

Place the drafting of upper and under part of sleeve on the lining with line *D* on the straight of this, trace through the elbow line and all round the pencil marks; also line *D*, leaving 1 inch all round for turning and alterations. Pin the linings together before cutting out [25].

Cutting Out the Bodice and Sleeves. Double width material should be kept folded as when bought; single widths, varying from 27 inches to 30 inches, should be folded selvedge to selvedge. Faced cloth, with the nap running downwards, satin, velvet, and velveteen (with the pile running upwards) require each piece cut separately, the same way as the pile [27]. Place the lining pattern on the material, arranging the pieces carefully. Pin in position, keeping the waist lines of back and curved side pieces on the straight of the material, and the selvedge of the lining of the bodice front to the selvedge of the material. Then cut out the same as the lining.

Basting Lining and Material Together. Great care must be exercised in basting; if this is imperfectly or carelessly done, the fit of the bodice will be impaired. Place right material front on its corresponding piece of lining, stretching the material slightly across the waist line of the lining; pin above and below this, turn over, and with a coloured cotton run lining and material together at the waist line. Turn it over so that the material is uppermost; take the pins out and place a weight (a flat iron will do) on the bodice just below the waist line; smooth up towards the shoulders and pin in position, then smooth across the bodice towards the front fitting line, also towards the outer seams. Pin again here and there, the lining to be loose and the material tight. See that the latter is quite smooth at the neck and armhole.

Move the iron as required. Baste up from the waist line, with a stitch ½ inch in length, outside the front fitting line towards the neck, outside the shoulder line, armhole-curve and down to the waist line [26]. Remove the iron and baste the basque below the waist line, keeping the lining and material smoothly together. Place the iron on the bust line, and with the fingers on the lining and thumb on the material, ease the lining into the material at that part, and tack down the centre of each dart.

Treat the left side of the bodice in exactly the same fashion, beginning the basting at the waist line of the under-arm seam and continuing right round the armhole, shoulder, neck line, outside the fitting line, and terminating at the waist line. Proceed with the basque and the darts in the same manner as the right front. The other parts of the bodice are pinned, arranged, and basted in the same way, taking great care not to stretch either the curved side pieces or the curved side of back.

Outline with coloured cotton all waist lines, front fitting lines, neck line, armhole curve, inset mark, elbow and wrist lines of sleeve. In basting the sleeve take care not to stretch the material.

Tacking. Pin the various portions together with fine pins, removing these as the bodice is tacked. Start with the centre back pieces; place the waist lines even and beginning from there, tack up to the neck, then from waist line to the edge of the basque (using small stitches), and always putting a double stitch at the waist line to hold it firmly. Be sure and tack in the wheel-marks or the bodice will be too large.

Next take the curved side-pieces and tack these to the corresponding part of back, starting this from the waist line as before. The curved portion of this can be very slightly eased by holding this part over the hand when tacking together to set smoothly with the corresponding part of back. The armhole lines should meet all round. Now join the under-arm pieces to the curved side-pieces, also the fronts at the under-arm and shoulder seams. When joining the shoulder seams, begin at the neck and slightly stretch the *front* to the *back* shoulder. Tack down the darts, starting at the top and working towards the basque.

Note. *If the darts are cut on the French system, the back one will have to be cut before tacking together, allowing ½ inch turnings. Be careful that the point is even, and stretch the back edge a little to the front, which, being very nearly straight, allows this to be done.*

To be continued

THE OFFICE BOY WITH A FUTURE

The Beginnings of a Commercial Career. First Steps in all Departments. Correspondence. Telephone. Simple Book-keeping.

By A. J. WINDUS

Concerning Lady Clerks. Commercial life, in its modern developments, offers many careers for women, though, fortunately, the economic conditions which have forced women into business competition with men have not lowered the average age at which young ladies enter the arena to that of the office boy. A boy usually passes straight from school to commercial life, whereas a girl on leaving school generally allows two or three years to elapse before seeking a situation in an office. This interval will have its duties, its devotions and its recreations, but time must be found for study also.

The field for lady clerks is an ever-widening one, but we may sum up the attainments required of them thus: Shorthand, typewriting, commercial correspondence, modern languages, double entry bookkeeping, acting as desk cashier. Other sections of this work are appropriated to the study of the three first-named subjects, but this is concerned almost immediately with double entry bookkeeping, a knowledge of which is becoming more and more of a necessity to the feminine applicant for a business post. When, in addition, she is able to take down shorthand notes from dictation, and therefrom produce a typewritten letter in French or German, it is easy to see that she is in a much better position to command a satisfactory price for her labour than her less studious sister.

The Boy's Career. We come now to deal with the boy about to leave school, who contemplates with mingled hopes and fears a career in commerce. It would be well for him at this stage to try and make sure that he has the qualifications essential to success. In the first place, is he fond of study, and especially of arithmetic, geography, composition, mental arithmetic and handwriting? Is he willing to recognise the fact that his education, so far from being completed, has only just begun, and that the experience of business he will gain by practice must be supplemented by the theory to be learned from text-books and professors?

Again, a youth should consider the direction of his own inclinations, and the nature of any talent his youthful modesty may have allowed him to discover. If the carpenter's bench possess more attraction for him than the office stool, let him not be ashamed to say so now; otherwise the day may come when he will curse the false pride which kept him silent. This warning is the more necessary because many boys make their choice of a career solely on the ground that it is one which has been adopted by a friend who has left school a few months previously. The best of friends may have very different tastes, and so a lad of a free, roving nature may become tied to a sedentary occupation in which his chances of success and contentment are small.

Attention must be paid also to the matter of health. This, no doubt, is a question rather for parents; but an intelligent boy should use some discretion in the matter, and it may here be said that he should endeavour, by taking exercise in the fresh air as much as possible, by regular and correct habits, and by having good and sufficient meals, to maintain and indeed to improve his health. Again, a reasonable ambition is most essential. It will show itself in a persevering desire for improvement in attainments as well as in position. It will concern itself not with short hours and large salary, but with moral worth and business capability. Lastly, to ensure success, a boy should have laid the foundations of a good character. This he will have to build up as the years go on, and he may be assured that, in spite of any contrary assertion, a reputation for integrity, fairness, and attention to duty will stand him in good stead.

The Boy Clerk. Assuming that he has decided upon his vocation, and upon the nature of the business he wishes to enter (in regard to which circumstances will probably limit his choice), the intending clerk must seek an opening with a good firm. Possibly this may be obtained for him through the influence of his father, an adult friend, or a teacher. Failing such help, the advertisement columns of a newspaper should be studied, and written application made in likely cases, while letters may also be sent to local firms in view of a vacancy occurring. Great care should be taken with letters as to the writing, the composition and the spelling. Boys are apt to make mistakes in the last-named which they could easily avoid even without consulting a dictionary. Mention should be made of any public examinations the applicant has passed, such as University Locals, Society of Arts, Scotch Leaving Certificate, College of Preceptors, L.C.C. certificate, etc., and copies of testimonials from schoolmasters or others enclosed.

Some little time may elapse before a situation is found. In the interval a candidate should endeavour to continue his education, especially taking pains to make up leeway in any particular branch. If he already knows a little shorthand, this should be regularly practised. Attendance at a "business college" is not recommended at this stage, but the opportunities for improvement afforded by the evening continuation schools and other evening classes should be taken advantage of. A good style of hand-

writing should be striven for: that known as the Civil Service hand is clear, and is likely to meet with the approval of employers.

Be Punctual. The time of waiting may be ended by a request from some firm for a youth to attend a personal interview. Little advice can be given in respect of this, beyond a caution to be strictly punctual in arriving. Frank answers should be returned to such questions as are asked. The interview may result in an engagement. Salary and hours of work will be named, duties briefly indicated, and in a day or two the youth will find himself installed as office boy.

In a large office there may be several boys; in a comparatively small house one will probably be sufficient. The duties to be undertaken will accordingly vary somewhat, but many are common to all offices. The necessity for obedience must be earnestly impressed on the beginner. This does sometimes, although not always, mean that he is to be at the beck and call of all and sundry in the office. Frequently, however, he will be "told off" to one person, and orders from him must be promptly and cheerfully carried out. It should be recognised at once that no office can be effectively conducted without a certain measure of discipline; and this is as necessary for the well-being of all the staff as it is for the good name of the house, in which its youngest member should early begin to take a pride.

Copying and Dispatching Letters. The office boy whose duty it is to get letters ready for the post is often known as the post boy. He will have to carry the letters when typed or written to a principal for signature, then to copy them in the appropriate letter books, write the addresses on envelopes, and stamp and post the packets in time for the mails. Anything which is put into an envelope in addition to the letter which has been copied is termed an enclosure, and the number of enclosures is marked on the letter: thus 3E means that there are three other things (usually papers of some sort) to go with the letter into the envelope before it is sealed down, and it is the duty of the post boy to see that all enclosures are properly dealt with. It is not proposed to describe the various methods in vogue of copying handwritten and typewritten correspondence. Practice alone will make perfect, and there are very few instances where the office boy or post boy will not be able to call on someone to show him just how to perform the operation. It may also be noted that printed instructions as to copying are to be found in some letter-books. For an explanation of special methods of press-copying, and of multiplying facsimile documents, consult the section of this work on Business Management.

Indexing Letter-books. A word or two as to indexing the letter-books may not be out of place. The object of keeping several letter-books going at the same time is to facilitate reference. Take, for instance, the simplest case where the letters from the Counting House are copied in one book, and those from the Showroom in another. It is clear that the indexing has begun from the moment that a letter is copied, because by that very fact it has been indexed to a certain book, although the name does not as yet appear in the index. If, therefore, a letter to William Brown, Esq., is copied on page 240 of the Counting House book when it should have been copied on page 375 of the Showroom book, the object of keeping two books has been defeated to this extent.

The best way to remedy the blunder would be to index the letter in the Showroom book, thus: Brown, Wm. 240 C.H. Book.

But stop a moment to think of the wholly unnecessary trouble to which everyone concerned is put by a fault of this kind, and be more careful next time!

Indexing the Books. The indexing of the letter-books is carried out daily or weekly. Each letter is entered alphabetically by name, the number of the page on which the letter appears being also noted in the same line. Sometimes there may be a doubt as to the correct arrangement when a Christian name forms part of the firm-name, as John Smith & Co. Should this be Smith & Co., John, or Smith, John & Co.? Reflection will convince the enquirer that the second method is open to misconception, as it is quite possible there might be a firm actually trading under the style of Smith, John & Co., and if we were to have dealings with both these firms, and were to index letters to each of them under the caption Smith, John & Co., confusion would result.

The system of cross references in indexing should always be adopted, as affording additional convenience to those who wish to look up letters. It consists in blue pencilling at the top of each letter-copy the nearest backward and forward pages respectively on which letters to the same person or firm appear. Thus, if there were letters to Messrs. Jones & Robinson on pages 8, 16, and 24, on page 8 would be written $\frac{-}{16}$, on page 16 would be written $\frac{8}{24}$, and on page 24, $\frac{16}{-}$. The last entry can only be completed if and when a further letter to Messrs. Jones & Robinson is copied.

Letter-filing. Letters received also require to be indexed. This may be done by means of one of the many files now in use, such as Stone's, the Shannon, etc. Incoming letters are often numbered, say from 1 up to 10,000, and then they can be indexed and cross-referenced, as in the copy letter-books. Instead of being filed, correspondence is often "Pigeon-holed." In this case the letters are folded to one convenient size, with opening to the right, secured in bundles and placed in the alphabetical compartments of a wooden frame or cabinet. In order to save time in referring to letters

1905

J. Ash & Co.

25 Jan.

when pigeon-holed, they are "docketed" or endorsed outside with the year, writer's name, and date, so that the letter required is easily picked out. Care should be taken that letters brought out for reference are replaced in the proper bundle without delay.

The Post Office Guide. The post boy will acquaint himself thoroughly with postal regulations, both as regards letters and parcels. He will know the hours when mails are dispatched to town and country, the rates of postage for home and foreign letters, the particulars as to registration, late-fee letters, dispatch of telegrams, etc. He should aim at being considered an authority in the office on these matters. His text-book will be the Post Office Guide, issued quarterly, or the local handbooks published by the Postal authorities in large provincial towns. Where small parcels are frequently sent by rail, the office boy should learn how to proceed in the matter, and know the ordinary rates and charges.

The Postage Book. It is probable the post boy may be required to take charge of the stamps, perhaps also of the petty cash. Every stamp used and every item of petty cash paid must be entered immediately in the books provided for the purpose. There must be no trusting to memory. For most cash payments a receipt or voucher should be obtained. This should be read through to see that it corresponds with what has been done, and is correctly dated. It must then be filed away in the manner in use at the office. A common form of postage book is as follows:

Received.		Date.	Name.	Where Posted.	Time of Posting.	By Whom Posted.	Amount.
10	-	1905 *Sept.* 1	*J. Carrick*	*Post Office Court*	6.30	*A. K.*	1
			Adams & Co.	*do.*	*do.*	*A. K.*	1
		2	*New Tyre Co., Ltd.*	*do.*	*do.*	*A. K.*	2
			L. A. Cox, Reg.	*do.*	11.30	*T. L.*	3

The amounts received from Petty Cash and laid out in stamps are entered in the left-hand column, and postages on the right. The difference in the two totals at any time represents the value of the stamps in the stamp box. The balance should occasionally be tested by another clerk. The person actually posting the letters should initial the postage book.

The Telephone. The office boy will have to attend to the telephone occasionally, if not indeed regularly. When giving a message, he must be sure that it is clearly understood, and when receiving one he should see that it is delivered at once to the person for whom it is intended. If he is out, a carefully-written note of the message should be placed in a prominent position on his desk. In some offices a telephone message form is in vogue, the systematic use of which will minimise mistakes and consequent annoyance. A specimen is as follows:

TELEPHONE MESSAGE.

No. *64* Time *10·45* Date *Oct. 15/05*

From *J. W. Mason* To *Us*

Enquiry.	Reply.
Can he see our Mr. Gray if he calls here in half an hour?	*Yes. Mr. Gray will be in until noon.*

Received / Sent by *H. S.*

The telephone in the general office is sometimes connected with others in different departments or in principals' rooms, in which case the method of using the "switch-board" must be learned. The card of instructions issued by the Telephone Company to its subscribers should also be studied.

Be Cheerful. We have by no means exhausted the list of duties, sometimes menial, often petty and humdrum, required of probationers in commercial life. Since, however, each house of business has its own conception of the uses of the office-boy, it must suffice to mention in a general way a few of the matters which may demand his attention, and to point

out that *the manner in which he discharges irksome tasks* is often taken into account by superiors when the time comes for the salary schedule to be revised at the end of the year or half-year, as the case may be. If, therefore, you are required to clean out an ink-well or to dust out a cupboard, do not be satisfied with half measures, but, because "Cleanliness is next to godliness," see that the work is done so that no one can find fault with it. If you have to make a copy of a document in your own handwriting, let it be an exact copy, not with a comma misplaced or a word spelled wrongly. If sent on errands be sure that you deliver your messages correctly. If, as sometimes happens, you should act as an "enquiry" clerk, always be scrupulously polite and obliging to callers, who are quick to judge the tone of the establishment from the behaviour of the enquiry clerk.

A Safe Rule. Cheerfulness and painstaking in the fulfilment of the "daily round and common task" are indispensable factors of worldly success. Learn to take pride in all honest work. Banish from your mind the distinction between important and unimportant matters, because, as a matter of fact, there are no such things as trifles, or if there be, you are not wise enough to be able to discern them. The safe rule is to put first-class work into everything you do, and it may help you to know that the world's great men have always paid great attention to detail. Genius has been defined as the capacity for taking infinite pains. The great captains of industry, who marshal the forces of production and distribution and control the vast movements of world-wide commerce, are men who combine executive ability and organising power with a capacity for grasping the smallest detail of business administration.

It should be unnecessary to state that betting, drinking, bad language, smoking and loafing ought to find no place in the category of a junior clerk's accomplishments. If, unhappily, he become addicted to evil habits, it does not need prophetic inspiration to enable an observer to predict a sad end to the usefulness of such a clerk. He will ultimately, unless a worse fate overtake him in the meantime, drift into the class of unemployed whose mournful cry is, "Too old at forty!"

Be Diligent. Solomon said, "Seest thou a man diligent in his business? he shall stand before kings." How true this is may be proved by citing one example, that of the great banking house of Rothschild, whose influence for peace or war has been felt in all the Courts of Europe because the attention to business of the founders and their successors has made the Rothschilds the controllers of millions of pounds sterling, and without money, which is the "sinews of war," war cannot be carried on.

Diligence, then, must be our watchword as we pass up from the ranks of office boys to the grade of junior clerk.

The diligent office-boy will discover one day that his status—that is to say, the estimation in which he is held by his fellow clerks and others—has been gradually improving. Having settled down to the office routine and acquired a certain degree of business method, it is more than likely that he will be able to spare an hour or so daily from his own duties to help someone else—the ledger clerk, it may be, who, for the sake of the assistance rendered, will readily give him an insight into his own more complicated work. Presently, when the ledger clerk's work increases beyond the point where he can cope with it single-handed, he will ask for a permanent helper. What more natural than that the youth who has assisted him from time to time should now be appointed to the post of assistant ledger-clerk?

The Junior Clerk. But, in whatever way promotion comes, the first step upwards cannot be taken until a proper aptitude for office life has been displayed. There is a case within our recollection of a young man who had performed the duties of office-boy for some years, only to discover at last that he was not suited to clerical work, and would have to begin his career again in some other sphere of activity. Surely a sad waste of time!

The change from office boy to junior clerk is likely to be a gradual one, but, as we have indicated, it will often show itself by opportunities for more advanced work. To recognise opportunities and to be able to seize them are the signs of business capacity, but there are some men who are said to create opportunities. These belong to the highest rank in commerce, and they are one and all students of books and men. Mr. Andrew Carnegie is a conspicuous example of this class, and it is partly because he made such good use of the free library in his youth that he has the means to endow so many free libraries to-day.

Book-Keeping. Clearly, then, we cannot afford to rest content with the amount of book knowledge we already possess. Two, three, or four nights a week might be devoted without injury to health to the study of commercial arithmetic, modern languages, Latin, or any other branch of knowledge in which the clerk may be specially interested, or which he thinks might be useful to him in his career. A knowledge of bookkeeping is considered indispensable to the vast majority of clerks, and it is hoped that our study of it may be profitable. It is but fair to the student, however, to explain that our treatment of the subject will not be conventional. We do not think it necessary to begin by defining the uses of certain books and forms which are fast becoming obsolete. These, undoubtedly, have practical as well as historic value, but it cannot be too earnestly impressed upon the mind of the student that the principles of double-entry book-keeping are always the same, although there is great diversity in practice. It follows, therefore, that if the student can get a clear notion of but one of the many up-to-date systems of double-entry book-keeping, it will pay him to do so rather than to spend time in learning how to keep books by an old-fashioned method, and how to adapt it to modern requirements.

PHYSIOLOGY

2

SYSTEMS AND ORGANS OF THE BODY

**How the Human Frame is Built. Heart and Brain.
The Six Systems of the Body and their Vital Unity.**

By Dr. A. T. SCHOFIELD

HAVING taken a broad and comprehensive survey of the plan of the human body, we may now look at the general construction of the body and its organs, and the materials of which it is built, reserving for later attention the minute and exact formation of these materials and their chemical composition. In addition, we may consider that change—or, as it is called, Metabolism—in which life consists, with the manufacture of body, heat, and the general gain and loss of the body. By the time these things are understood we shall be in a position to follow intelligently the physiological and vital actions of the various systems of the body.

How the Body is Built. In a building such as the body it is well to begin with the *unit* the building unit. In a house this is a brick or a stone; in all living structures, animal and vegetable, it is a *cell*. Just as all bricks are very much alike, whether used to build a palace or a pigsty, so are all cells, whether they are built up into mice or men, or even into fruits or flowers.

All living structures, therefore, whether animal or vegetable, are built up of cells (which we shall consider in due course), and these cells are grouped together for different purposes to form different tissues. The *tissues* are the different materials of which the body is made; just as clothing may be made of silk, cotton, or woollen tissues or materials. There are eight principal tissues in the body: *bone, gristle, muscle, nerve, skin, fat, fibre,* and *connecting* tissue.

1. The *Osseous*, or bone tissue, is the framework of the body. This material is found, of course, in every part of the body and forms the skeleton.

2. The *Cartilaginous*, or gristle, forms the joints of the body. This tissue covers the ends of the bones to form the joints; it unites the ribs with the breastbone; it forms the rings of the windpipe and the lid of the larynx at the back of the tongue; the lower part of the nose, the upper eyelid, and the ear.

3. The *Muscular*, or muscle, forms the machinery of the body. This tissue covers all the bones with flesh, which is muscle, and is the chief part of a number of machines by which every movement is performed. It is also an important tissue in the wall of the abdomen and the floor of the chest.

4. The *Nervous*, or nerve tissue, is the moving power of the body. It is the chief constituent of the brain and the spinal cord, inside the backbone or spine. It also forms the nerves, which run like white threads from the brain to all the muscles, and gives them power to move.

2. THE BRAIN AND SPINAL CORD

5. The *Epithelial*, or skin, forms the outer covering of the body. This tissue is the skin that covers the body outside, and lines it as mucous membrane inside, and also forms the teeth and nails.

6. The *Adipose*, or fat, forms the under covering of the body. This tissue is the inner protective sheathing and padding of the body, beneath the skin, and round the internal organs. It consists of drops of oil, enclosed in separate cells.

7. The *Fibrous*, or fibre or sinew, is the tissue that forms the cords and bands of the body. This tissue makes the strong tendons that fasten the muscles to the bones, and forms the covering or sheath of the bone itself, and the various organs.

8. The *Connective*, or cementing tissue, joins all the parts and cells of the body together. This substance is found everywhere, all over the body, and is like the mortar in a house, fastening all the bricks together. It is a sort of network of cells and long fibres.

Special Systems. These eight tissues are combined together into various groups of *organs* or SYSTEMS for special purposes. These groups are *six* in number, and include: the *circulatory, respiratory, digestive, excretory* or *secretory, locomotor*, and *nervous*. There is also the *reproductive*, which is considered in the section on BIOLOGY. We may divide these six into three groups of two each. There are two in the chest:

1. The *Circulatory* system is that by which the blood or liquid food is distributed all over the body to all the tiny cells. This system includes the heart or force-pump, and the arteries, capillaries, and veins, or the three sorts of pipes through which the blood travels.

2. The *Respiratory* system is that by which we breathe, and by which the body is fed with oxygen, which gives the blood its bright red

colour. This system includes the nostrils and mouth, the windpipe and the lungs.

Then there are two in the abdomen, or stomach:

3. The *Digestive* system, by which all the food is made into liquid and changed so as to nourish the body and pass into the blood. This system includes the mouth, gullet, stomach, liver, pancreas, intestines, and other organs.

4. The *Secretory*, or excretory, system (for they are best grouped as one) manufactures the various fluids of the body, such as bile, urine, sweat, saliva, gastric juice, etc. It consists of various glands or secretory organs in different parts of the body, such as those in the skin, the kidneys, the lymphatic glands, the spleen, etc. It also gets rid of the refuse of the body.

Lastly, there are two in the head and limbs:

5. The *Locomotor* system, by which all movement is effected. This includes the bones, joints, and muscles.

6. The *Nervous* system, by which all the body is controlled, directed, and regulated. This system includes the brain, spinal cord, and the special senses, such as the ear, the eye, and all the nerves.

We have considered already the division of the body into *two tubes*, the *posterior*, which, with the limbs, is the seat of the engine, or the *animal life*; and the *anterior*, that of the boiler, or *vegetable life* of the man.

Man's Brain. We shall first consider the head, including the face, and the spine, or the engine (the posterior tube). Then we may look at the *chest*, or upper part of the boiler (the anterior tube), where the steam is made, and, lastly, at the *abdomen*, or lower part of the anterior tube, where the fuel is burnt.

The *head* and *spine* contain the principal nervous systems of the body and four organs of special sense—*sight, hearing, smelling*, and *tasting*.

The *brain*, which fills the head, consists of two parts: the *Cerebrum*, or greater brain [9], and the *Cerebellum*, or lesser brain, placed behind and below the larger one. The greater one is about the size of a melon, and the lesser one of a small orange. From this brain nerves run to every muscle of the body, enabling them to move the limbs and body as the mind directs; and another set of nerves run from every part of the body and skin to the brain, enabling the mind to know and feel all that goes on. The brain is connected with the spinal cord by a flat band of brain matter, that lies on the inside of the occipital bone, called the *Medulla Oblongata*, or the Oblong Marrow. The *spinal cord* [9] runs through a large hole in the occipital bone and right down the open tube formed by the spinal vertebræ, to the bottom of the back-bone, and all along its course nerves leave it and enter it, as in the brain.

The organ of sight consists of the two eyes, which receive every image that we see, and transmit it to the brain. The organ of hearing consists of the two ears, by which we receive all the waves of sound that we hear, and transmit them to the brain. The organ of smell is in the upper part of the nose; the organ of taste at the hinder part of the tongue.

The organ of the voice is contained in the larynx in the neck, which joins the head to the body. Just under the chin in front of the neck you can feel what is called the *Adam's Apple*, which is the front of the larynx, or voice-box, by which the air coming out of the lungs is formed into sounds. The sounds are formed into words by the mouth, tongue, and teeth.

The Chest. The *Chest*, or *Thorax* [10], forms the upper part of what may be termed the human *boiler*. In it the blood, which is like the *steam* of the body, is purified and circulated. The *thorax* is closed above and below: above, by the neck, through which the windpipe enters it in front, conveying air to the lungs; and by the *gullet* behind, conveying food to the stomach. Below, the floor, dividing it from the abdomen beneath, is formed by a very large muscle stretching right across the body, called the *Diaphragm*, or partition wall, also called the *Midriff*. The thorax is walled in at the sides by the ribs, and behind by the backbone, in which is the other tube that contains the spinal cord. The thorax contains the two organs of *respiration* and *circulation*.

The *lungs* are the organs of respiration. They are like two sponges filling the right and left halves of the chest. Wherever you can feel a rib there is part of the lung underneath. Each of these lungs is contained in a bag, like a skin, that separates it from the ribs, and is called the *pleura* (from *pleuron* = a *rib*), but the lung is not *inside* the bag.

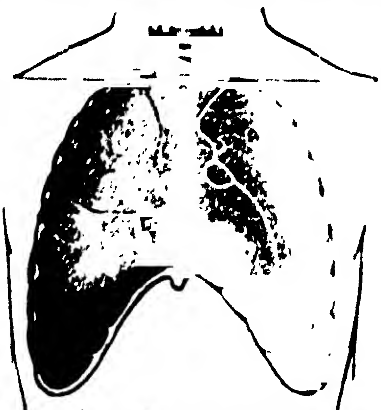
You will understand how this is possible if you take a paper bag and a sponge, and, instead of putting the sponge inside the bag, place it against the outside, folding the empty bag round it. The sponge will then be wrapped up in the bag, yet *outside* it, covered by *two* layers of paper.

The *outer* layer of the pleura is fixed to the side of the chest, the *inner* layer to the lung, and the two layers move on each other like a joint when we breathe.

The lungs are full of small air cells with minute tubes leading from them. These gradually increase in size as they join together, till at last they unite in one large tube, or bronchus, for each lung. These two bronchi join together, and form the *windpipe*, or *trachea*, which conveys the air through the larynx into the mouth. The windpipe is kept stretched widely open by a series of elastic rings of gristle. Behind the windpipe is the gullet, leading to the stomach. These rings in the trachea, it is interesting to note, are incomplete behind, where the trachea lies against the gullet, or œsophagus. They thus form springs rather than rings. The reason for this is that the walls of the gullet, being quite soft, if the cartilage rings rested against them, would form a series of ledges on which food would inevitably lodge, and thus interfere with deglutition, or swallowing. Here we get one of

those minute points on which the physical comfort of life depends. We take air into the lungs to pass thence into the blood, and thus be carried to all the cells of the body to enable them to live and breathe.

The Heart. The *heart* is at the lower part of the chest, between the two lungs. It is a *fleshy* or muscular organ, about the size of the fist—flat above, and pointed below like a sugar-loaf. It lies in a slanting direction behind the breastbone—the broad part, or the *base*, of the heart being upwards and partly to the *right* of the breast-bone; the point, or apex of the heart, being downwards and to the *left*, where it can often be seen beating against the chest-wall. The heart is hollow, and acts like a pump, forcing the blood all over the body through the great vessel that leaves the heart at the upper part. The heart, like the lungs, is enclosed in a double layer of folded bag, called the *pericardium*, because it is round the heart.



10. THORAX AND CONTENTS

The *gullet* runs right down the back of the thorax, and passes out through the diaphragm, which forms the floor, into the abdomen.

The *abdomen* [11] forms the lower half of the trunk, and is often called the *stomach*. Many parts of the body are called by more than one name, which frequently causes confusion. Thus the trunk, which is made up of the *thorax* and *abdomen*, is sometimes called the body, of which it really only forms a part. In the same way the word stomach is often applied to the whole abdomen, of which it only forms a very small portion. The *trunk*, as we have seen, is composed of the thorax and abdomen—which together form the human boiler, in which, by means of food fuel beneath and air above, steam is generated to work the engine, which in the body consists of the brain and spinal cord.

The abdomen, which forms the lower part of the body, is full of organs belonging to the *digestive system* and *secretory system*, by which the fuel or food is rendered fit for use in the blood and the body.

11. THE ABDOMEN

The *walls* of the abdomen are not protected by ribs like the thorax, but are all formed of flesh or muscle. The principal organs they contain are the *stomach*, the *liver*, the *pancreas* or *sweetbread*, the *spleen* or *milt*, the *kidneys*, the *intestines*, and the *bladder*. We shall reach them all in due course.

Man's Framework. All these organs and systems are held together and formed into one body by means of a framework, partly fixed and partly movable, partly rigid and partly flexible, partly hard and partly soft.

The skeleton part of the framework is made of bone; flexibility is given to certain parts by means of joints, which are simply smoothed and rounded ends of bone covered with gristle to avoid friction, and joined together by fibre and ligament for strength. This forms the rigid and hard parts of the framework. The flexible and soft part, which everywhere covers organs and muscles, is composed of a layer of fat to preserve the warmth, as fat is a non-conductor, and an outer covering of skin.

This framework is exquisitely adapted to give strong protection to the vital parts so that they cannot readily be injured; and the whole of the organs are so arranged and stowed away that, as we saw in the last chapter, a perfect human body is a beautiful object, full of symmetry and graceful curves and lines.

The Vital Spark. But more is needed than this for a living body; there must be a vital unity. So far, all we have is a picture of six systems, constructed in different proportions of eight tissues, and held together in bodily shape by an elaborate framework, and containing a large number of complicated organs. But all this is complexity, not unity. Where is the centre, where the directing power that starts the engine, and moves all the machinery in perfect rhythm, all unconsciously to its owner, who has, as we all know, but scant power to interfere with any great vital processes, and none at all to direct them?

This is the very point on which so many of our text-books are silent, and therefore fail to give us, in all their descriptions, a true conception of a human being, and are wearisome and dry, because the living soul, the vital spark, is absent.

The Mind and the Body. Any student of a modern medical text-book on physiology can well understand how the mass of dead material facts, which fill its pages, would be "vitalised" if their dependence on the central directing force were laid bare, and the unity that underlies diversity in man demonstrated. "The mind so acts on the body," a well-known authority has put it, "that .... the body performs only a

limited range of its functions without intelligent (unconscious) direction."

Some governing centre must regulate, control, counteract, guide, and arrange and unify the actions of the human organism with regard to the continual succession of differing events, foods, surroundings, and conditions which are ever affecting it in endless succession, and in constant variety, enabling it, amid this bewildering multiplicity of changing influences, to hold on its steady course of growth, health, nutrition, and self-maintenance with the most marvellous constancy.

It is quite clear that this governing centre is mental in nature and unconscious in character, and whether we call it "Nature" or the "Unconscious mind" matters little, so long as we recognise that it is this mind that not only vitalises but unifies this wondrous body, and blends all into one living personality.

Soul and Spirit. But a man, as we have seen already, is even more than an animated and unified body. He has not only his personality and his bodily vitality to maintain, but also his relation with this world and the next, and to this end he is endowed with a soul and spirit, placed in connection with and under the control of a conscious mind. By means of his *animal* life he maintains his relation with his environment and becomes a part of all around himself.

By means of his *spirit* life he has intercourse and relations with what is above him, with the unseen world, with abstractions, with the ideal, with the Infinite—with God.

This tripartite being - governed, as regards the body, by an Unconscious Mind, and, as regards soul and spirit by a Conscious Mind—this, and nothing less than this, is a *man*.

CONSTRUCTION OF THE BODY

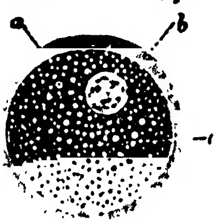
The Cell. In considering the minute construction of the body, we must first of all examine the *cell*. Let us first grasp the broad fact that not only are we alive, but that our bodies are throbbing and pulsating with millions of independent and active cell lives, over which we reign as autocrats. We have more living subjects in the body than the Czar of Russia has in his vast empire. That is the statement of a literal fact. These subjects are, fortunately for us, not directly under the sway of our capricious wills and passions, but are calmly and wisely governed for our good by the unconscious mind.

Let us then clearly grasp the fact that the body is *alive* everywhere but on the surface. The *outside* of the skin is dead, as we shall see later, but every other part is alive. Whenever we enter the body (figuratively) we are surrounded with the most varied and busy existences, all pursuing their different tasks, callings, and occupations for the common good, and thus forming an ideal community, under the wise and beneficent sway of the all-powerful autocrat—the unconscious mind. This is no fancy picture, but sober fact; and every fresh detail of physiology that comes to light confirms it. The *cell* [12] forms the basis not only of Physiology, but of Biology; for it is the Embryological (the construction of life), Morphological (the form of life), as well as Physiological (the process of life) unit.

This fact was first established by Schwann, of Germany, whence most of our facts come. This cell consists of two essential parts, the *body*, and a darker part inside it called a *nucleus*, and sometimes of cell wall, which makes a third. Every part, not only of animal, but of vegetable organisms, is built up of cells, which consist, therefore, essentially of a *nucleated mass of protoplasm*, varying in size in the human body from $\frac{1}{3000}$ inch in the blood to $\frac{1}{300}$ inch in the brain

Protoplasm. Protoplasm is a living, transparent, viscid, insoluble, unstable substance of a proteid nature, containing 70 per cent. of water. It coagulates with heat at 130°, and dies when the body is raised to this temperature.

A cell manifests its vital properties in that it is *born*, *grows*, *multiplies*, *shrivels*, and at last *dies*.



12 A CELL, showing its structure
a, Zona pellucida; b, germinal vesicle; c, protoplasm

During its brief life it assimilates food, *breathes*, *works* and *rests*. It is capable of spontaneous motion, and frequently of locomotion. It can secrete and excrete substances, and, in short, it presents nearly all the physical phenomena of the life of a human being.

BIRTH. Cells are produced only from cells by *gemmation* or *fission*. The former, a budding off of a small part of the cell, is rare in man. *Fission* is a dividing of the whole cell, including invariably a part of the nucleus. The process is very quick, and may take place in a few minutes.

GROWTH. The cell rapidly increases in size to a certain definite point, which it maintains during its adult life, like a human being.

DECAY. As it gets older it is frequently removed further from its source of life (the blood-stream), making way for more vigorous life (as in epidermal structures), and gets wrinkled and smaller and flatter, like an old person.

DEATH. After a life of from a few hours to a few days, it finally dies and dries, becoming in the skin a mere horny scale on the surface of the body. Internally its death is frequently brought about by its breaking up or dissolution, as in the secreting glands, where the cell itself dissolves away to form the secretion—such as saliva.

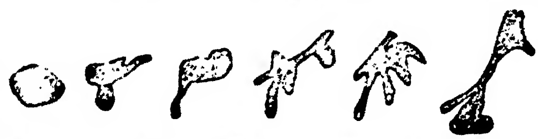
ASSIMILATION. It can take in food from the blood by absorption; or, as in the *amœba* (or freely moving cells), by flowing round a substance of a solid nature, and thus enclosing and subsequently digesting it.

RESPIRATION. The cell inspires oxygen (O) and expires carbonic acid gas (CO_2) which is

probably the result, as it is in man, of its *metabolism*.

Work. This is of the most varied kind, and embraces the formation of every tissue and every product — solid, fluid, or gaseous — of the body.

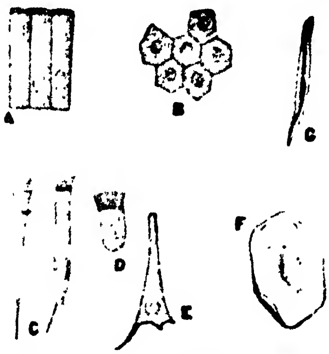
Rest. This work may be intermitted. It is found that in the dark the colour-cells cease to secrete pigment. Muscle-cells and all others have intervals of rest.



13. A WHITE BLOOD CORPUSCLE; VARIOUS PHASES OF ITS MOVEMENT IN THE BODY

Motion. This interesting quality of cell-life has only been carefully studied of late years. Most cells have a limiting membrane or *cell-wall*, consisting merely of the hardened exterior of protoplasm. This, however, is in many cases capable of assuming the most diverse shapes, known as *amœboid movements*. If a colourless corpuscle is examined on a warm microscopic slide in a saline fluid, it is seen constantly to change its shape by pushing out or retracting some part of its mass.

In vegetable cells, spaces or *vacuoles* occur within the mass, and are continually changing their shape, so as to cause the granules in the protoplasm to flow in streams. Another beautiful form of motion is found in ciliated movements.



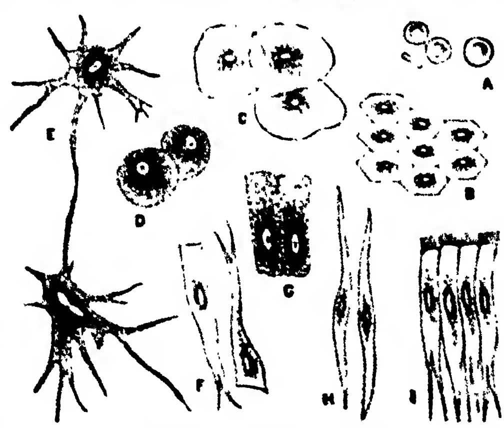
14 KINDS OF EPITHELIAL CELLS

A, Columnar cells of intestine; B, polyhedral cells of the conjunctiva; C, ciliated conical cells of the trachea; D, ciliated cells of frog's mouth; E, inverted conical cell of trachea; F, squamous cell of cavity of mouth, seen from broad surface; G, squamous cell, seen edgeways

The *ciliated epithelium*—the lining membrane of the air-passages and other parts—consists of cells having on their surfaces rows of from ten to thirty small hairs, which are incessantly moved with a distinct *lashing* motion in one definite direction, several times every second. Some cells move by the lashing of a long filament at the end of the small cell, by which they can progress for some inches.

Locomotion. Cells may move actively or passively. In the blood the cells are borne along by the current, but colourless corpuscles seem able to make their way actively and at will—if we can speak of will in such bodies—about any part of the body. Their movements appear to be guided by some sort of instinct, and are by no means haphazard [13]. Careful research by Metschnikoff at the Pasteur Laboratory has shown that colourless corpuscles flock to any part of the body, where any inflammatory or infectious process is going on (from the leg to the cornea, for example), and there do their best to rid the body of any intruding bacteria by swallowing them. *Amœboid* cells of this type have been seen to work themselves up through the deeper tissues surrounding the bowel, pushing aside layers of cells in their course, and emerge into the intestine, and then seize on bacilli, and after swallowing them, make their way back again.

Animal Cells, all originally of a more or less rounded shape, attain the most varied forms, in accordance with the tissues to which they belong [14]. They may become hexagonal, as in many internal membranes; polyhedral, discoid, as in the blood; prickly, as in the epidermis; scale-like, as on the surface of the skin; columnar (like bricks on end), as in the deepest layers of the skin; cubical, as in many organs; wedge-shaped, as in the salivary glands; crescent-shaped, branched, stellate, as in nerve tissues; fish-shaped, forked at one end, as in the ureters; canoe-shaped, as in muscle; or ciliated, as already described. Again, they may become fibres, as in connective tissues; or tubes, as in capillaries [15].



15. VARIOUS BODY CELLS

A, Blood cells; B, pavement cells; C, epidermis cells; D, lymph cells; E, nerve cells; F, ureter cells; G, columnar cells; H, smooth muscle cells; I, ciliated cells.

The cells are mostly connected together by *intercellular substance*, originally produced by their own bodies. This consists of a material like protoplasm, only without vital properties, or it may consist of deposits of lime salts, or of fine fibrillar material. The cells may, on the other hand, be in direct contact with one another, and united by thin walls or processes. From these two materials, of which the cells are the bricks, and the intercellular substance is the mortar, the whole of the body is built up.

IDEAS
2

THE INCALCULABLE POWER OF IDEAS

Ideas which have Changed the Face of the World. Creators of New Industries. Pioneers of Revolution. The Golden Key of Fame.

By ERNEST A. BRYANT

WHEN the British Association met in South Africa in the summer of 1905, two striking illustrations of the power of an idea were afforded to even the most casual observer.

The first was well expressed in the inaugural speech of the President, Professor G. H. Darwin. He said: "Bartholomew Diaz, the discoverer of the Cape of Storms, spent sixteen months on his voyage, and the little flotilla of Vasco da Gama, sailing from Lisbon on July 8, 1479, only reached the Cape in the middle of November. These bold men, sailing in their puny fishing smacks to unknown lands, met the perils of the sea and the attacks of savages with equal courage. How great was the danger of such a voyage may be gathered from the fact that less than half the men who sailed with da Gama lived to return to Lisbon. Four hundred and eight years have passed since that voyage, and a ship of 13,000 tons has just brought us here in safety and luxury in but little more than a fortnight."

Conquest of Time and Space. The comparison would have been still more striking had Professor Darwin mentioned then, as he did mention at a later meeting of the same august body, that his own great-grandfather, Dr. Erasmus Darwin—whose speculations in the direction of natural selection had in some measure anticipated his illustrious grandson's investigations—had predicted, a century and a half earlier, the means by which the British Association was enabled so rapidly to make the passage. But when Erasmus Darwin spoke of engines driven by steam, he spoke to men in what to them was a parable, which they did not understand any better than men of all preceding time had understood. The germ of the idea was in many men's minds, but Watt and Stephenson were yet unborn, and there was no one to bring it to birth.

The second thought which must have struck the observer was that though the British Association was meeting six thousand miles away from London, yet we were all able at breakfast on the following morning to read the report of their proceedings, their excursions and discussions.

Steam and the Telegraph. In those two instances of facilitated and safe travel, and the rapid transmission of news from one hemisphere to another, we have typical examples of the power of an idea. Steam has existed ever since the sun warmed the waters of the earth; yet not until Queen Victoria had been a year upon the throne did it occur to man seriously to apply it to navigation by employing it to drive a vessel across the ocean. All the possibilities of the telegraph were of coeval birth with civilisation, but the practical application of the idea antedated the steamboat by only a year. And then its projectors dared not dream how vast and significant was their creation. They little thought that, fourteen years later, a cable weighing 2,500 tons would be laid across the Atlantic. Only its detractors were certain as to anything. They "knew" that the project must fail; they "knew" it for another eight years. And then the Atlantic was effectually bridged by electricity, and the thousands of miles separating the old world from the new rendered as inconsiderable as the distance between one parish and another.

The value of the idea which gave us wireless telegraphy we are even now unable to estimate. So illimitable is the horizon opened by this new phase that not the most speculative can fix the limit of its scope. It may change the conditions of our lives in many ways of which we do not dream. Our relations with distant friends, to think of one example only, may be entirely altered; the friend across the world may become an almost next-door neighbour. One thing is certain—in the not distant future we shall see the boast of Ariel left a relic of a dark age. The cables have already done for us what he promised; they do put a girdle round the earth in forty minutes. What the new principle will effect will be to send the human voice the same journey in one-sixtieth of the time.

The First Lucifer Match. The significance of an idea can never be realised at the moment of its birth. The alchemists were the first to discover the readiness with which sulphur can be ignited, but they left their discovery at that. Meanwhile men, civilised and savage, sought their fire as men had sought it from prehistoric days. The savage rubbed wood; the civilised plied flint and tinder as they had been plied from the dawn of the iron age. Then came a simple Stockton chemist, to whom occurred the idea of making the first lucifer match from pieces of wood dipped in chlorate of potash and sulphur. At one bound the ages were left behind, a boundary between civilisation and savagery established. Even more striking was the advance made when the light of coal-gas first beamed forth upon the waters of the Thames from the pioneer lamps upon Westminster Bridge. The oil lamp of the savage was rough and crude and filthy; that of the philosopher and warrior of cultured Greece and Rome beautiful and ornate; but both were the same in principle. British history in Parliament was all made by candle-light, or by the feeble flame of the bowl of fat and wick of fibre. Then a man's idea literally illumined the dark

places of the cities of the world; and the electric light, wonderful as it is, was the less wonderful when it came, because of the manifold merits of its predecessor and rival.

Intellectual Capital of the Race. These are facts which enable us, by contrasting the present with the past, to appreciate the power of ideas. The ships with which Nelson crushed the naval might of Napoleon were but developments of the war galleons of the primeval Norsemen, and depended upon the principles on which the savage relies as he cuts his way through the waters of the silent rivers of America or Africa. A single first-class ironclad of to-day would sink the combined fleets of Nelson and Napoleon. And men's brains are daily exercised to bring about new devices which shall render the present fleets of the world as useless as the old warships of unarmoured oak.

When a thinker gives an idea to the world he increases the intellectual capital of the race. He cannot say in what proportion profit will be reaped; he cannot always predict in what direction results will tend; he cannot, from his close-range view, see very clearly whether his discovery be a pearl of price or merely a day-dream, unworthy of permanent record. He must put it to the test. Alfred Russel Wallace, dreaming his feverish dreams in the Moluccas, was too modest a man to let himself believe that he had solved a gigantic problem when one afternoon there flashed in an instant upon his mind the idea of Evolution, the survival of the fittest, and the variation of species. That evening he drafted his theory; on the two subsequent nights he elaborated it. Then he posted off his notes to Darwin. Neither had guessed that the other was working on the subject; neither for a moment suspected that he was about to create a revolution in thought which was to rouse the whole civilised world to the highest pitch of excitement. But Darwin, as we all know, was already engaged upon the work of his life, fearing meanwhile, as he replied to Wallace at the time, that "my work will not fix or settle anything." He did fix and settle a great deal, as it was his privilege in after years to feel assured. But there are countless secrets yet to be rapped out of the stony bosom of Mother Earth. Darwin and Wallace and their school gave us the hammer wherewith to do the tapping.

How a Pestilence was Destroyed. As well by example as by precept, leaders of thought and action teach us how imperative it is alertly to act upon inspiration. Louis Pasteur, whose mighty brain was a magazine of ideas, impressed upon his students that "in the field of observation, chance favours only those who are prepared." His own record is a signal exemplification of the power of an idea. What to the ordinary, unimaginative analytical chemist would be the significance of two vats of beer containing, the one sour beer, the other good? To Pasteur it meant the opportunity to revolutionise chemical and biological science. It meant to the world that a great and devastating pestilence was to be struck dead. The microscope revealed the fact that the globules of the sound beer were nearly spherical, while those of the sour beer were practically globular. Experiments showed that wine and beer and milk are turned sour by the growth of atmospheric organisms, and that when these are excluded the liquids remain sound. If wine and beer and milk can be kept sweet when protected from putrefactive germs, why not other forms? Lord Lister, as he told us in a memorable address, seized upon Pasteur's discovery, and the antiseptic treatment for wounds was born.

A Revolution in Surgery. Until then, anæsthetics, that Godsend to suffering humanity, had proved rather a curse than a blessing. In the days when operations had to be borne by conscious patients, the man with the readiest knife and strongest nerve was the most successful craftsman. A serious operation must be raced through, or not attempted. With greater leisure afforded for more extensive and delicate operations, the scope of the surgeons was enormously enlarged. But pestilence stalked in the wake of the new discovery. Gangrene became epidemic in the hospital wards of the world; in places it was attended by a mortality rate of over sixty per cent. after operations. With Pasteur's discovery developed by the master hand of Lord Lister, surgery was revolutionised, and no operation impossible.

No person imagines that the birth of even so epoch-marking an idea as this constitutes a royal road to perfection of knowledge. Pasteur's and Lister's investigations read like a fairy tale. Lister's in particular thrills with human interest, as we see the great mind of the thinker groping from the dark into the light; see him win his first triumph over putrefaction of the wounds by the use of carbolic which caked upon the incision, and by the use of a spray which time proves unnecessary; then see him finally attain perfect mastery of the subject. With the antiseptic treatment added to anæsthetics no wound need now be declared hopeless, no organ of the human system too remote or delicate for effective treatment.

The Birth of an Industry. Into the gravest research and study humour will creep. We laugh at the bizarre and fantastic ornaments of savages, yet a fashion of the early part of the Victorian era was found by the scientific mind of Dr. Buckland to depend upon a misconception more ludicrous than any embraced by traveller's tale or creation of the humorist. Beautiful women, Society leaders, were wearing as charms, as earrings, bracelets and what not, highly polished substances which were understood to be rare British minerals. Certain markings and other evidences gave the brilliant Dean of Westminster a clue, and led him to an analysis of the curious adornments. The result was as he had suspected. The charms and earrings and so forth, set in gold and decorated with gems, were simply the fossilised excreta of extinct monsters by which our island was once inhabited. The discovery would

have been startling and interesting to the archæologist but nothing more had it remained there.

To the ordinary mind there does not appear any clearly traceable connection between the earring of a Society belle and a vast agricultural industry. But the second grew out of the first. Buckland recognised that in these age-old deposits, of which vast quantities were available in certain valleys and river-beds, were properties of value to agriculture. Liebig, the great German chemist, happened to be in England at the time, and the Dean took him to inspect the deposits. He saw at once that they must contain abundance of phosphate of lime. He took back some to Germany, and there made a careful analysis which bore out his theory. And from that discovery originated the great industry of superphosphates which has wrought such enormously important results for agriculture.

Future of Our Food Supply. We pay a princely salary to the man who can cook better than his fellows, who can invent new dishes from conventional material; and we make the *chef* as much a hero as if he seriously benefited humanity. For the man who does not affect the habits of the *gourmet* there is quite another hero—the Berthelot, who, from experiments in a common garden and his laboratory, devises schemes for feeding the multitude. It may be a scientific Utopia impossible for realisation, but he has pointed to a day when his schemes will enable us to convert our farms into parks and gardens and to look to the laboratory for our food supply. Every man will carry in his waistcoat pocket his tabloid supply of food, each pellet containing all the properties essential to the maintenance of life.

Such is the Berthelot dream—the dream of the man around whose work synthetic chemistry has grown to proportions undreamed a generation ago. It may be only a dream, but it is not idly to be dismissed without examination. In a rather fierce generalisation, Dr. Russel Wallace has declared that whenever the scientific men of any age disbelieve other men's careful observations without inquiry, the scientific men are always wrong. It is well to remember this warning, without unreservedly accepting it, when doubt is cast upon the promises of a Berthelot. That man should make a meal of a pellet seems hardly less probable than that he should shiver a mountain by the aid simply of liquid air, or extract from coal-tar the most exquisite dyes and scents, a substitute for sugar, a substitute for quinine, and an increasing number of amazing products. Every theory which Pasteur enunciated was denounced by some of his most illustrious contemporaries, yet in each he was right. He who had never seen a silkworm was the man destined to cure the ravages which were ruining the silk industry. He was the man whom the world was destined to bless for providing cures for, and preventives of, hydrophobia, and diseases which were slowly but surely exterminating domestic poultry; for finding the antidote for anthrax, a malady by which the whole world, animal and human, has from time to time been scourged.

Fighting Plague by Science. The field for great enterprises is still largely virgin soil. Men like Sir Norman Lockyer look to sunspots wherein to read the secret of famine and pestilence in India. Others, like Sir Clements Markham, keep their eyes upon the earth, and there win relief and benefit for the million. The story of this great man's introduction of quinine into India is the story of a noble idea daringly, unfalteringly carried through. He had to procure the tree from Peru, and the dangers and difficulties attending his task were innumerable. But he succeeded, despite all perils, and has been allotted his place in history as having performed a service of the highest value to humanity. What it means may be estimated from the fact that, unless checked by quinine, malarial fever kills more people every year in Southern India than the worst of cholera epidemics. Now, quinine is the one sovereign specific against this deadly fever. In the same category with Markham come men like Sir Joseph Fayrer, whose researches were undertaken outside his ordinary sphere as a surgeon, with a view to combating snake bites. Pioneers, each in his own path, these men translate into acts ideas for saving our great Dependency from plague, pestilence, and the poison of the serpent.

In spite of all that has been achieved, however, there remains much to be done in our tropical colonies. In India alone five million people died in 1900 from malarial fever; and there have long been more places than Sierra Leone meriting the description of "white man's grave." It remained for a soldier-scientist in Major Ronald Ross to elucidate the mystery of malaria and yellow fever; to show, after years of dispiriting effort, that the malaria germ enters the poison gland of the mosquito and is transmitted thence to the blood of the human being. The remedy is, so far, to do away with the swamps and marshes in which the mosquitos breed. Dean Buckland created a sensation by preaching in Westminster Abbey from the text, "Wash you, make you clean," at a time when cholera raged in England. Major Ross preaches cleanliness, sanitation, drainage. The remedy is primitive in its simplicity; but the idea which led to its discovery has given its possessor immortality.

Radium. When Sir Humphry Davy spoke of "radiating matter," he used a phrase which had no meaning for his generation. A century was to elapse before the idea developed fully in the minds of the gifted M. and Mme. Curé, who were to discover radium to the world. And then, at a bound, scientists were transported to a world whose border-lines had so long eluded them. Infinitesimal as are the quantities in which radium has so far been found, sufficient has come to hand to demonstrate the possibility of its revolutionising science. A competent authority has calculated that there is stored in a single grain of radium sufficient energy to raise 500 tons to a height of one mile, and for an ounce of it to drive a thirty horse-power car round the world.

Its potentialities as an illuminant, too, seem

boundless—even the blind are made to "see" its light. Most important of all, as a curative agency in disease radium seems destined to take a commanding place. Already certain forms of cancer have been cured by its aid, and we are only at the beginning of our knowledge as to its wonder-working attributes.

Ideas Beget Ideas. Such are some of the ways in which the ideas of thoughtful men benefit the race, and, step by step, bring us nearer to the millennium. Every discovery begets more discoveries. Pasteur's investigation with the sour wine and beer gives us antiseptic treatment in surgery; it also makes possible the preservation of food, so that the delicacies of the four corners of the earth may be brought to augment the meagre resources of our own little land and our indifferent climate. Berthelot, to assist in the defence of Paris, invents explosives which prove of such importance in industrial arts that their value for the purposes of warfare becomes by comparison insignificant. Maxim, during his service in the great Civil War of America, has the idea of his machine gun "kicked" into him, as he expressed it. The "kick" of the rifle was so much wasted energy; he conserved that energy to make the most formidable fighting weapon of its character then known to the world. The builder of the Tay Bridge, warned by the tragic failure of the man whose effort had preceded his, has to formulate a new plan. Its execution is beyond the capacity of the tools at his command. He invents his tools as he proceeds, and, incidentally, a new industry springs up from this unsuspected source of wealth. There was a call for new implements, though its existence had not occurred to him.

Ideas which were Rejected. There is always a call for new ideas. Statecraft needs them; the empire of business needs them more. The pity is that a brilliant idea may at times be turned to evil account. Joseph in Egypt was the father of "corners." His beneficent prudence saved Egypt in the day of famine. Unhappily the idea has been seized upon by the unscrupulous to make profit at the expense of the many—to "corner" the food of the people. It is to the credit of the British Government that it has before now rejected brilliant ideas which might have been applied to the arts of war. The war-plan of a former Lord Dundonald was refused as being too terrible to employ against civilised foes; and, upon the same grounds, the invention of Lord Playfair for the discharge of shells which set fire to ships and garrisons, and asphyxiate an entire corps or crew, was shelved. Many terribly ingenious plans for war are banned for the like reason. The inconsistency of it appears in the fact that while an army may not poison the drinking supply of an enemy, any public or private body may with impunity poison the rivers in its own country. For the man who can solve the problem of river pollution in England there awaits a rich reward.

The Man of Ideas a National Asset. The day of the dreamer has gone. So many minds are applied to problems that, if the guerdon is to be secured, the man with an idea must see to it that none other comes before him in making plain his discovery. It is to the undying glory of European scientists that all their greatest discoveries are given without money and without price to the world. In America the custom is not always so chivalrous; the aid of patent law is invoked for discoveries in pure science which, if made in England, would be freely laid at the feet of the people. This, however, is a consideration which does not affect the many; the dividing line is sharply drawn between ideas upon which the world has a legitimate claim, and those whose profit should rightly accrue only to their originator. The point is, that all who set themselves to the elucidation of problems, great or small, must seek without delay practically to apply them. Science must now be applied. The scientific recluse to whom his laboratory is the whole world declaims against this theory. But study for study's sake must be the delight of the selfish few. The man of ideas is a national asset upon whom his country has definite claims. It was a discovery of national importance to Germany when her chemists discovered how to make artificial indigo, for they killed India's great trade in the natural product.

The Application of Ideas. There must, then, be no delay in the application of discoveries to their proper use. Procrastination may mean that a man who rightfully should be acclaimed a pioneer may become merely a follower. Great minds run frequently upon similar ideas. The memoirs of Darwin and Wallace on Natural Selection were read upon the same day before the Linnæan Society; Cros and Ducos de Hauron simultaneously communicated their process of indirect photography in colours. Graham Bell was only two hours ahead of Elisha Gray in patenting the telephone. Many other instances might be cited of simultaneity in discovery. In every field the searchers are busy, but there are many mines yet to be located.

For the art of war initiative and organisation are ever commanded. For the arts of peace there must be even greater alertness. The case remains as Pasteur put it: "Two opposing laws seem to be in contest. The one, a law of blood and death, opening out each day new modes of destruction, forces nations to be always ready for battle. The other, a law of peace, work, and health, whose only aim is to deliver man from the calamities which beset him. The one seeks violent conquests, the other the relief of mankind. The one places a single life above all victories, the other sacrifices hundreds of thousands of lives to the ambition of a single individual. Which of these two laws will prevail? God only knows! But of this we may be sure, that science, in obeying the law of humanity, will always labour to enlarge the frontiers of life."

MATERIALS AND MECHANISMS

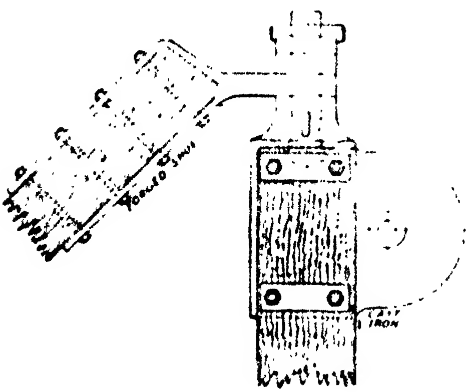
The Study of Applied Mechanics—continued. Beds and Framings. Mechanisms and Materials. Rigidity and Elasticity in Mechanisms

By JOSEPH G. HORNER

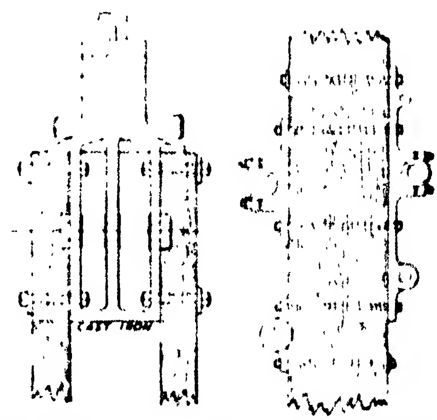
IT is not intended to consider here the strength of materials in the abstract, from the point of view of tests, and of the character of the various stresses to which they are subject. That is being done in the Course on MATERIALS AND STRUCTURES. What is proposed here is to observe how materials are selected and employed in the construction of machines, with a view to the utilisation of their characteristics to the best possible advantage.

It is necessary to remember some points mentioned in the preliminary chapter of this Course, especially those concerning economical manufacture and suitable factors of safety. The design of machinery can never be regarded apart from manufacturing conditions, and the machine tools and of steam engines. Those of machine tools have to be large enough to receive numerous heads, slides, and spindles, those of engines must combine supports for cylinders and slides, and bearings for shafts and spindles. In modern practice nearly all mechanism tends to greater complication, machines increase in dimensions, rendering modifications in design necessary, one of the principal of which is that massive framings often have to be built up in several separate pieces, united with bolts.

Design of Beds and Framings. In considering, first, the design of beds or framings one would like to know how to apply the lessons on the strength of materials which are gathered



1. MAST AND GUY OF TIMBER-FRAMED DERRICK CRANE, CONNECTED WITH A CASTING AND A FORGING.
The forging is in severe tension.



2. MAST OF TIMBER-FRAMED DERRICK CRANE
Fitted with cast iron bearings

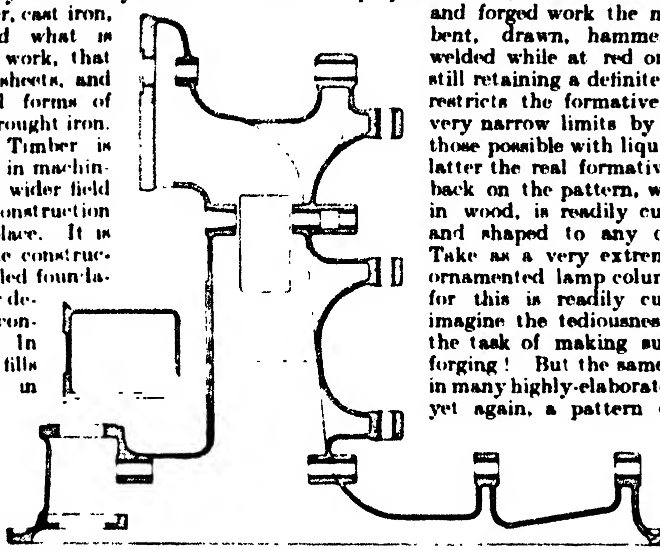
testing machine is but a basis upon which design is embodied by the aid of that experience which cannot be disregarded.

The Basis of Mechanisms. We have seen that a movable mechanism is properly distinguished from the rigid base or the framing to which it is attached, both of which in combination comprise a machine. This distinction is very important from the point of view of materials used. Generally a base, or a bed, or frame is massive by comparison with the mechanism which it carries. It is, moreover, almost invariably of much more complicated form than any of the single elements of which the mechanism is built up, because its form has to be designed to receive the various points of attachment of those elements. Familiar illustrative examples occur in the framings of various at the testing machine. It is as well to caution the student that very precise results are not attainable in this direction. That is, though the testing machine shows that cast iron, say, is capable of sustaining enormous crushing stresses of 40 to 50 tons per inch, it would not do to make a machine framing subjected to such stresses very thin and light by calculations based on tests. If you look at an approved design of bed or frame you see that though it may never be subjected to more than a few tons of load, it is so designed that the imposition of hundreds of tons would be required to crush it. This is due to several causes, such as complications in the stresses, the principal kind being that of the setting up of vibrations of more or less intensity; the rapid changing of stresses from one kind to another, and also the imperfections inseparable

from manufacture, these being of an incalculable character in some cases, as when hidden defects occur which no test piece could reveal. No cautious engineer ever assumes absolute soundness in work: he systematically regards it all with suspicion, and then allows a large margin—*factor of safety*—for the unforeseen contingencies which experience tells him are practically certain to arise sooner or later. Metal is not massed out of caprice, for it is such expensive stuff that the aim always is to use as little as possible consistently with safety, but the trained designer knows that in many cases it must be *lumped*, because his experience reminds him of cases where a cheese-paring economy in this direction has resulted in costly failure.

Materials Used in Framings. *Considering the materials used in beds and frames,* we find that they are strictly limited in number. They are timber, cast iron, cast steel, and what is termed plated work, that is, plates and sheets, and rolled sectional forms of mild steel, or wrought iron.

Timber. Timber is very little used in machinery, but in the wider field of mechanical construction it fills a large place. It is employed in the construction of roofs, piled foundations, and other departments of contractors' work. In machinery it fills a useful place in some truck framings, in some crane framings, receiving attachments of metal [1 and 2], but it has been largely displaced by the plated type of construction, or by that in which rolled joists and other allied sections are used.



3. EXAMPLE OF A "BOX" TYPE OF CAST FRAME, HAVING NUMEROUS BOSSES FOR SHAFT BEARINGS.
The bearings are bushed with bronze.

Cast Iron. This is the material which is employed to an immensely greater extent than any other for machine bases and framings. The reasons for this are the following.

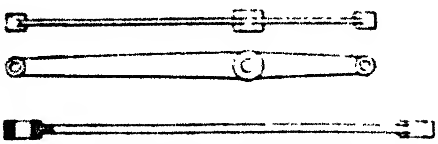
It is cheaper than any other cast material, costing in the form of castings from £8 to £12 a ton on an average. Some exceptionally intricate work may run up to double these sums. It is, therefore, not so cheap that it can be used in a reckless fashion. But steel castings are about twice as expensive, and so is average plated work.

The fact, too, of a bed or frame being produced by casting practically limits the choice to iron in very many cases. Looking at a complicated framing [3] having bearings, bosses, lugs, bracketings, etc., standing out in awkward positions, the fact becomes obvious that by no other method than that of producing the shape in a mould, and pouring in liquid metal, could an economical construction be practicable. This is different from saying that it is impossible—it is only, commercially speaking, impracticable. Therefore, we find that in those cases where framings are produced by building up with plates and rolled sections, these are only adopted in relatively simple designs, or else designs are modified to embody simplicity. Hence in these, of which many crane beds and framings afford excellent examples, the plated work is all plain, comprising mostly rectangular outlines; and awkward shapes are made in the form of small castings, and bolted to the plating [18].

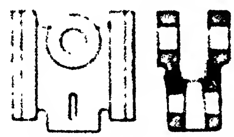
The great advantage of casting is, of course, due to the fact that the metal is poured while in a liquid state, so that it will fill any impression prepared for it, however intricate. In plating and forged work the metal can only be bent, drawn, hammered, rolled, cut, welded while at red or white heat, but still retaining a definite solid form. This restricts the formative processes within very narrow limits by comparison with those possible with liquid metal. In the latter the real formative work is thrown back on the pattern, which, being made in wood, is readily cut, and built up, and shaped to any outline whatever. Take as a very extreme case a highly ornamented lamp column. The pattern for this is readily cut in wood, but imagine the tediousness and expense of the task of making such a column by forging! But the same contrast obtains in many highly-elaborated framings. And yet again, a pattern once made, does duty for scores or hundreds of similar founders' moulds, while a piece of plated or forged work stands alone in its manufacture.

Value of Rigidity. Another good reason why cast work is preferable to plating for main framings is that it is more rigid. The reason lies in the fact that mild steel and wrought iron are immensely more ductile and elastic than cast metal, and they, therefore, vibrate much more under variable stresses than cast metals do. This is a very important point, because vibration is one of the worst evils that can be present in almost any machine or engine. In machine tools the sole reason why beds and frames are stiffened up so enormously in excess of that required for mere strength is the elimination of all traces of vibration. Most of these framings are perhaps from fifty to a hundred times stiffer than they need to be if mere strength to resist fracture were alone considered. A mere trace of vibration would result in chatter and inaccurate work, and would produce wavy marks on the cut surfaces. This necessary

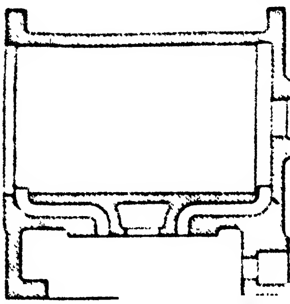
rigidity can be obtained with far greater certainty in cast than in plated or forged work.



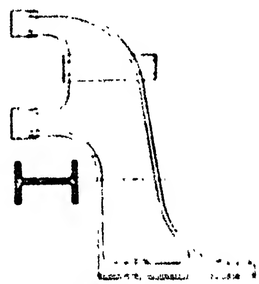
4. LEVER AND COUPLING ROD.
Would be too brittle if cast, but when forged resist tensile and bending stresses.



5. AN ENGINE, OR PUMP CROSS HEAD.
Made indifferently by casting or forging.



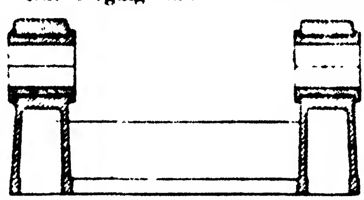
6. AN ENGINE CYLINDER.
In making this, casting is the only practicable method.



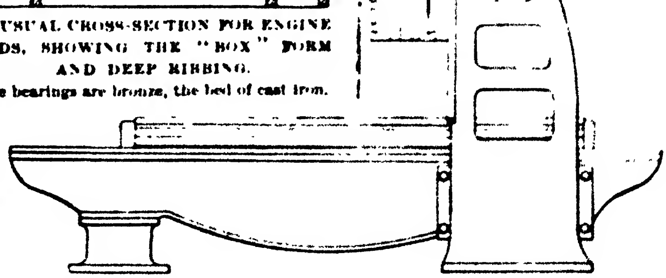
7. RIBBED FRAMING
This has been nearly superseded by the "box" type

Castings *versus* Forgings. If, again, we compare castings with forgings, we see at once the reasons why each occupies a different sphere of utility from the other. Forgings are not so readily made as castings unless large quantities are required alike, in which case die forging effects immense economies. But forging and casting each occupy a distinct and strongly-separated sphere. A casting is rigid and brittle by comparison with a forging, and is therefore to be preferred when rigidity is essential. A forging is tough and ductile, and is, therefore, employed for pieces of small section, as rods, levers [4], small cranks. There is a border line where either is used indiscriminately, as in small pieces of many kinds, used in all mechanisms, and subject to comparatively little stress [5]. In these, die forging comes into increasing rivalry with castings. But in the main portions of engines and machines there is seldom any question as to which should be employed. Casting scores in all cylindrical work subjected to much wear and stress, and having many branches, holes, and passages. Among the best examples of this kind are engine cylinders [6] cored out; hydraulic cylinders, and pump barrels, typical of many others. It would be practically impossible to produce such forms by any forging methods, although where lightness is an object sought, much intricate forging is done by bending and welding. But it is costly, and the rigidity obtained in castings is another reason why the examples just mentioned must be cast, even if it were practicable to forge them.

Arrangement of Metal. There is, however, another reason for the superiority of cast to plated work for framings, besides that due to the difference in the ductility and elasticity of the materials. It is due to the fact that the metal can be arranged in a very economical and efficient fashion in a casting, by making the latter hollow, a case which is paralleled in the hollow form of columns. At one time most framed castings were plainly plated, and ribbed round the edges [7], now such a gaunt wasteful design would not be tolerated in heavy machine framings. It is well understood that a given amount of metal massed in a solid column will, if arranged in the hollow form, be much stronger. So in all hollow machine framings, termed the boxed type, the maximum of massiveness, strength, and general rigidity is combined with the minimum of material [8 and 9]. It is a by-issue that in many of these the interior is utilised for cupboards



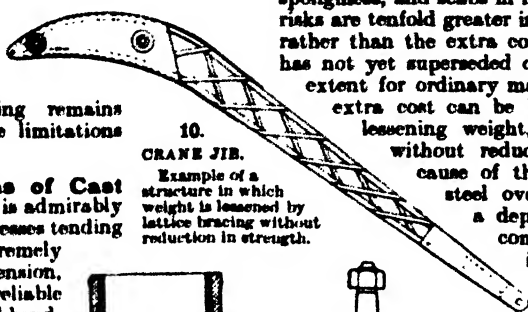
8. USUAL CROSS-SECTION FOR ENGINE BEDS, SHOWING THE "BOX" FORM AND DEEP RIBBING.
The bearings are bronze, the bed of cast iron.



9. PLANING MACHINE FRAMING WITH PARABOLIC TYPE OF BED AND HOUSING.
The form best qualified to resist bending stresses.

and shelves; the boxed form preceded those utilities.

We understand now, therefore, why cast iron is used for the majority of framings, and why these are made massive, and generally of hollow form. But something remains to be said about the limitations of cast iron.



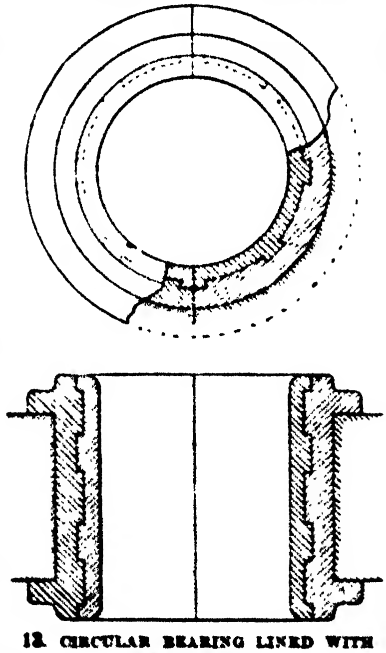
10. CRANE JIB. Example of a structure in which weight is lessened by lattice bracing without reduction in strength.

The Limitations of Cast Iron. This material is admirably suited to withstand stresses tending to crush, but it is extremely weak if subjected to tension, and is not thoroughly reliable to resist transverse and bending stresses. These differences have to be taken account of in design. Cast iron is loaded directly to an almost unlimited extent, but it is rarely subjected to a direct pull. It is often subjected to cross bending, but the factor of safety must be high in that case, and the nature of the loading must influence the factor. A perfectly quiet or dead load is the most favourable, a vibratory or live load is risky. But by increasing the depth of a section [see the bed *A* in 9, and parabolic housing *B*] which has to be subjected to bending stress, ample strength may be secured, because strength increases directly as the square of the depth. This in conjunction with the requirements of rigidity just discussed explains the reason of the depth given to horizontal engine beds, to long lathe beds, and allied designs.

Cast Steel. The only serious rival to cast iron for framings is cast steel. This would be used to a much greater extent than it is but for the difficulties of producing sound castings. The value of the material lies in its greater strength to resist all kinds of stresses, tensile and transverse as well as compressive. The writer has a vivid recollection of early attempts to substitute steel for iron in parts of crane work. It was impossible for many years to produce the most ordinary steel castings free from blow-holes, while many were cracked locally in addition.

11. PUMP BARREL. Made of cast iron, lined with brass.

12. AIR PUMP ROD. Of rigid steel, sheathed with brass to prevent rusting.



13. CIRCULAR BEARING LINED WITH WHITE METAL. Held in dove-tailed grooves.

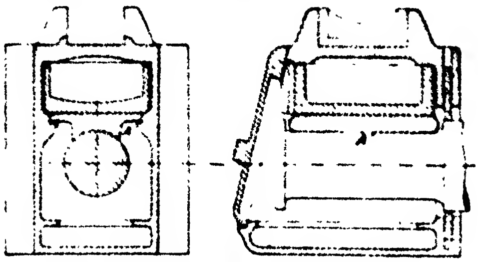
These difficulties, well-nigh heart-breaking to the steel founders, are not yet entirely overcome. There is always some risk of blow-holes, sponginess, and scabs in iron castings, but these risks are tenfold greater in those of steel. This, rather than the extra cost, explains why steel has not yet superseded cast iron to any great extent for ordinary machine framings. The extra cost can be largely discounted by lessening weight, which can be done without reduction of strength, because of the greater strength of steel over iron. But directly a departure is made from comparatively plain castings, equally proportioned in their various parts, shrinkage stresses come in to complicate the difficulty of making sound castings free from blow-holes.

Lessening of Weight in Framings. There are other cases now to be considered in which an entirely opposite condition exists, in which the object is not to mass metal, but to reduce it as far as possible, consistent with safety. It occurs chiefly in designs of which the bridge is the best type, and which it is necessary to lighten as far as practicable, because the weight of the structure itself forms a considerable percentage of the load which it has to sustain.

At one time nearly all wrought iron bridges were formed of solid or continuous plates, a most wasteful design, because the metal over very large areas was altogether far in excess of that necessary for security, and represented, therefore, so much useless load which the bridge had to carry. In a modern lattice girder bridge there is not more metal used than is required for safety. The lattice bars and booms are never arranged in a fanciful style, but the strength of every individual bar is calculated for the loads that will be imposed on it, both in nature and intensity. Thus a bridge with a maximum of strength and the minimum of weight is obtained. And what is done in the bridge is done also in all structures in which a similar principle is involved. It applies to the lattice beams of overhead travelling and bridge cranes, to the jibs of cranes [10], to the inclined hoist

ways of blast furnaces, to the columns of gas holders, and railway station roofs, and to the roof principals when these are built of steel.

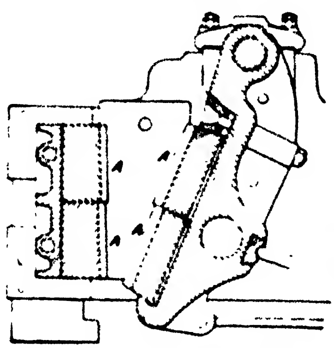
When speaking of materials it is not possible to pass over without remark the revolution which the use of mild steel as made in Bessemer and open hearth processes has effected in the design of machinery. First, the heavy timber work of the old millwrights gave way to cast iron, and this to wrought, to be displaced by steel. The result is an extended and ever increasing employment of the latter, with diminution of weight and more elegance of form.



14. AXLE BOX FOR RAILWAY WAGONS.
The main box is made of cast iron or steel, but the actual bearing A is of bronze or of white metal.

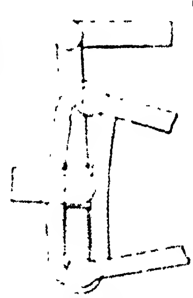
15. CAST IRON TROLLEY WHEEL.
Chilled around the tread to lessen wear.

Essential Mechanisms. We next consider the selection of materials for the actual mechanisms, regarded apart from their bases, and soon find that conditions are much more varied in these than they are in those which control the selection for the bases of machines. To the questions of stress and strength are added the problems of movements of various kinds, the turning and sliding referred to in the previous article, with the involved problems of friction. Each of these offers separate difficulties, and all must be overcome in detail in the production of a practically perfect and workable mechanism.

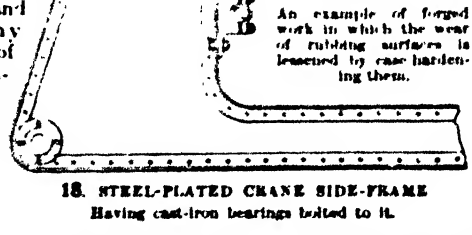


16. JAWS OF STONE BREAKER.
Having removable pieces, A A, of manganese steel for durability.

Materials. Into the construction of moving parts many materials enter. They include cast iron and cast steel, forgings in iron and steel, very many grades of alloys of copper, tin, zinc, aluminium, etc., with minute admixtures of other elements, and made up in the forms of castings, bars, rods, tubes, sheets, some of which, too, are subjected to special treatment, as hardening and tempering. Let us note the principal conditions which have to be fulfilled in the moving parts of mechanical structures.



17. REVERSING LINK MOTION.
An example of forged work in which the wear of rubbing surfaces is lessened by case hardening them.



18. STEEL-PLATED CRANE SIDE-FRAME.
Having cast-iron bearings bolted to it.

It is of the very greatest importance to consider the general question of strength. The first and most essential condition to be fulfilled is apparently, as in the base or frame, strength to resist stress and strain, or deformation and fracture. This is a very comprehensive way of putting the matter, because the term strength is so very embracing and covers so much of detail. It may be strength to resist compression, or tension, or bending, or torsion, or steady loads, or variable loads. First, then, the nature of the stress for each member must be ascertained, and its amount estimated with as close an approximation to facts as possible, and then the suitable material selected and duly proportioned.

Rigidity and Elasticity. With few exceptions bodies are assumed to be rigid, using the term in its practical sense. When a body yields to stress and becomes deformed in consequence, the degree of elasticity by virtue of which it has yielded is of great importance, because it must in no case be such that it remains a *permanent set*. On the removal of the stress, the elasticity must be equal to the complete removal of the deformation. This, therefore—the elastic strength of the material—measures its capacity to resist stress, and not the actual or absolute strength to resist fracture, and it is a fundamental distinction ever to be borne in mind in designing mechanisms.

Now, some materials are more rigid than others, and some are better qualified to resist one kind of stress than another, and this is the reason for the selection of one or more materials in preference to others for given duties.

Cast iron, as we have seen, will not endure much tensile stress, and therefore it is rarely employed in such service. But forged materials, and some cast alloys, as those of copper and tin with phosphorus, or with aluminium, will, and these, therefore, are materials used largely in parts subject to tensile stresses, such as moving rods of various kinds, in pumps, engines, and mechanisms generally. They lack the rigidity in compression which castings possess, and therefore if used as compressive members their area must be calculated on a liberal basis.

Cost. The grading of materials by alloying elements in which iron and steel are included gives the designer any kind of material required for a given duty, hard and tough, or hard and strong, or elastic, as best adapted to resist the stresses imposed, and much of the art of the designer lies in making a suitable selection from the wealth of materials available.

Here again the question of cost acts as a corrective. Often a very desirable material has to be discarded for one less suitable because of the difference in price. But there are many dodges practised which are more or less familiar, such as making parts in sections, facing or supplementing a cheaper with a more costly material, as in some pump rods and barrels [11], a plan which is adopted for other reasons also, as in frictional devices.

Friction. The division in our first article of elementary mechanisms into turning and sliding pairs suggests the problem of friction. There are mechanical devices such as lubrication, the use of long bearings, ball, and roller bearings with a view to lessen friction, but materials also are selected with this object. Steel may run with steel, turning on balls or rollers, but not with sliding surfaces. A steel shaft or cross head must move in cast iron, or on a bronze, or brass, or a white metal alloy. But cast iron may slide on cast iron, or on either of these alloys. Wrought iron will not slide well on wrought iron, but it will on cast, or on brass. The diminution of friction is essential to the durability of a moving mechanism, just as the strength of the material has to be correlated to stress to prevent deformation of fracture. 12 to 14 are familiar examples of designs to diminish friction.

Hardened Surfaces. Intimately associated with the question of durability is that of certain mechanical processes by which the physical characteristics of materials are changed. We allude to hardening processes effected by the smith or the foundryman. When a surface has to be subjected to prolonged and severe friction it is rendered as hard as glass, either by taking advantage of the presence of carbon or by impregnating its surface with carbon. The first is the hardening of the smith effected by quenching red-hot steel in water. It is also the method of the iron founder, who rapidly changes the carbon from the graphitic to the combined condition, by chilling—i.e. pouring the metal against a cold iron surface which forms that portion of the mould. The chill only extends to a depth of from one-eighth to half an inch or thereabouts [15]. Or loose jaws of hard steel are fitted as in the stone breaker [16], or in the bottoms of mortar pans. The second is the method adopted when a forging contains no carbon, as in wrought iron and mild steel. A surface coating of carbon is produced by case hardening—that is, subjecting the forging to the influence of carbonaceous substances in the presence of nitrogen in a closed box maintained at a red heat for several hours, as in the link motion 17.

Factor of Safety. The factor of safety, already mentioned several times, is so important a subject that it calls for some observations of a practical character. This factor signifies the difference, the relation, or ratio between the safe working load and the ultimate or breaking strength of a structure. It may, however, be conveniently taken as the relation between the working load and the elastic limit, or elastic strength, and if so, that must be clearly stated. But in either case it means that when the strength of a structure or a part of a mechanism has been arrived at by calculation or test, it must never be subjected to any stress corresponding with that strength, but to a lower stress, often very much lower.

Methods of Loading. It is well known that the stress that strains least is that of a dead load, or a load which does not change either in intensity or character. The load on foundations and piers is of this character, and so generally is that on beds and baseplates carrying machinery. Here the factor of safety is low, often not exceeding three in iron and steel—that is, the structure would be made three times stronger than the calculations for strength would give. It is higher for materials liable to decay, as timber, for which it may be from seven to ten, or to bad jointing, as masonry, where it might range from ten to twenty.

But when the load is a live one, the factor must be higher. A live load signifies one that is being imposed and removed constantly. One of the most trying loads of this kind is that of soldiers marching over a bridge, hence the reason why they have to break time then. A terrible accident happened once to a bridge in France due to the marching of soldiers in time. Another severe live load is the rolling load of a train running over a bridge. So is that of a jenny running across a travelling crane. In these cases the dead load factor is doubled, or trebled generally, doubled if the stress is of one kind only, and often trebled or nearly so if of two kinds as tension and compression alternating.

Yet again loads may be impulsive, or of the nature of sudden shocks, such as occur in the lifting of crane loads, with the rapid surgings that are set up. These are incalculable, and in such cases factors of safety of from ten to fifteen or even twenty are allowed in some members, or from three to four times as much as for dead loads. Very often, therefore, crane framings are made of plated steel and the bearings only in cast iron [18].

But more has to be considered yet in fixing this factor. As we cannot always calculate the nature and intensity of the stresses on a structure, the value of experience comes in to determine how much to allow. And yet again the quality of material and of the workmanship has to be taken into account, until at last we find that the results arrived at with the testing machine have gone but a little way in helping the designer, who has to apply this knowledge to workable mechanisms.

Variations in Materials. This last remark opens up another broad field about which a big volume might be written, the variations in materials nominally alike, and in the character of the workmanship put into mechanisms. These are quite as important as any of the other conditions already discussed in determining how much a machine may be trusted to perform and endure.

It is because materials, nominally alike, vary so greatly in strength, ductility, soundness, and other characteristics that specifications are often made very strict, and inspectors appointed. We may have some cast iron twice as strong and tough as other cast iron, and similar differences will be found in other metals and alloys. A nice clean test piece of timber an inch or two inches square and a foot long and free from shakes and knots, gives but a misleading idea of the strength of a commercial balk a foot square and twenty feet long. Neither does a test bar of cast iron tell anything about the condition of the interior of a heavy casting poured from the same ladle. And, further, most materials deteriorate in the course of years, notably timber, but also iron and steel and the rest. They are subject to fatigue, due to overwork, and then bend or break under a much smaller stress than they have successfully endured millions of times previously. They may become corroded, with diminution of section, and all these things must be taken account of. Because of this, factors of safety are often made high in the first place, and working loads reduced from time to time, just as is done regularly in steam boilers.

Workmanship. With regard to workmanship, this enters into all practical determinations of factors of safety. It applies to castings which often have hidden faults, to the processes of welding, punching, and reamering, to the drilling of rivet holes in bridges, to boiler work, to methods of riveting and caulking, to the nature of the fitting on engines, and to machinery involving an immense amount of detail. A badly made mechanism will soon knock itself to pieces, a well fitted article has a long life before it. These facts, barely mentioned here, indicate the need for an extensive acquaintance with shop practice on the part of the designer. He must know the faults incidental to the work of foundry and forge, of the turnery and machine shop, and of the fitting and erecting departments.

The Curve and Fillet. There is another aspect of design which, though it may appear of small moment, is yet of very great importance, namely, the employment of the curve and fillet instead of the keen angle. Angularity is not only an eyesore, but it is a great element of weakness. Put a radius in a re-entrant or internal angle, and the chances of fracture through that angle are vastly lessened. This is not due to the slight extra metal hardly at all, but to the better arrangement of the crystallisation which results. It is most apparent in cast metals where crystals arrange themselves normally to the cooling surfaces. But in forgings it results from the continuity of the fibres not being broken, which is the reason why fullering tools never have square edges, but always convex ones.

Facilities for Repairs. The designer of mechanical structures has to regard another matter—an entirely practical one, that of affording suitable facilities for building up, and taking apart a mechanism for repairs. When these are necessary—and they inevitably arise in all kinds of mechanisms—the more rapidly this can be effected the less will be the delay and expense. Many draughtsmen would fail in this if left to themselves. The subject is too wide to be illustrated here, but briefly it involves the designing of a mechanism in such a way that it shall not be necessary to dismantle it all to effect a slight repair. That is, if a shaft or broken wheel or a valve has to be removed, it ought to be possible to do so without pulling the whole thing to pieces. Good designers bear this in mind, others do not.

These are some of the practical every-day aspects of a subject that looms large in the applications of practical mechanics. It is as important to understand the characteristics and the faults and weaknesses of the metals and their alloys as to know how to estimate the nature and intensity of the forces acting on mechanical elements. The behaviour of materials at the testing machine is but one side of the subject. That of their characteristics developed in manufacture through the various shops is of equal importance, and this knowledge is gathered in the foundry and forge, in the turnery and machine shop, in the mechanism in course of construction, and when under final test.

TRAVEL
2

THE PERSONAL VALUE OF TRAVEL

Travel as an Essential Factor in the Development of Mind. A Means of Joy and Profit. Its Mental and Utilitarian Side

By J. A. HAMMERTON and WILLIAM DURBAN, B.A.

TRAVEL is one of the most effective factors in the development of individual character. That greatest of English schoolmasters, Arnold of Rugby, used to say that he always found that the boys who had never visited London, and who had never caught sight of the ocean, were the most difficult to impress with any notion of the greatness of the world and the stupendous possibilities of life.

The genuine scientific phrenologist and the sound metaphysician both alike testify that the exclusive cultivation of the faculty denominated "inhabitiveness" tends to dwarf the mind. Home becomes dearer after some amount of nomadic experience, and, as "change is the spice of life," according to a very sensible standard of philosophy, nothing is so perfectly calculated to refresh the mind as change of scene. It is a fallacy to imagine that travel far and wide in any degree weakens the delight that the finest natures take in the amenities of domestic life. The exact contrary is the case. The true human soul is finely poised in its emotional equilibrium, and, unless distorted or decadent, it balances evenly the love of continuity and the desire for change.

What Great Men Owed to Travel. The relation between character and travel is remarkable. The vast majority of the ruling spirits of the world have derived their matchless qualifications, in no small degree, from the enlarged knowledge of men and things gained by actively and extensively moving about the world. Catherine the Great is not usually reckoned among the much-travelled women of history; but she knew her native Germany well before she went to Russia; and after her accession she frequently took immense journeys through her vast dominions, toilsome though such pilgrimages were. The most renowned conquerors and the grandest nation-makers have in all ages been amongst the most adventurous travellers. No Roman ever saw so much of the Empire and of the regions beyond its various borders as Julius Cæsar. Little Greece could not hold Alexander, and it was by marching far away into another continent that he became "the Great." Paul, the greatest of the Christian Apostles, was one of the greatest travellers of early ages, and he it was who consolidated Christianity. Napoleon, before he gained renown and attained to Imperial power, knew Italy almost as well as France, and had made intimate acquaintance with Syria and Egypt. His rival and conqueror, Wellington, had roamed about India before he was called on to lead our forces through European campaigns. Nelson not only took his victorious squadrons to the shores of the Levant, to the coasts of Egypt, to Italy, to Denmark, to Teneriffe, and to the West Indies, but he everywhere showed an enthusiastic interest in the countries and the peoples he thus visited. As a young midshipman he had the privilege of an Arctic voyage, which helped immensely to enlarge his mind.

We only have to go back, in the history of great men, to a few memorable names, and we begin afresh to see how wonderfully foreign travel, as well as wandering in the most interesting realms of one's own land, must have influenced the development of intellect. Milton knew and loved Italy when to visit that fair land was no mean undertaking. He could write Italian poetry almost as well as a native. We should never have had Longfellow's matchless prose romance, "Hyperion," but for his extraordinary familiarity with Germany. Few books on European travel are so delightful as the "Views Afoot" of that vivacious American, Bayard Taylor, who walked thousands of miles in Europe when a mere lad. Browning is the poet of other lands as well as of England, and by his easy familiarity with international social customs became what Dean Farrar in his great lecture called him, "the poet of universal humanity."

Modern Leaders and Travel. Do Englishmen generally appreciate the fact that King Edward gained the most valuable part of his education when, as Prince of Wales, he visited America and then India? His Majesty is as much at home in France and in Germany as in England, and he doubtless owes his broad popular sympathies to the fact that his numerous journeys and frequent sojourns abroad have totally precluded any tendency to insularity in his sentiments. The present President of the United States is astonishing the world by his versatility of resources and his boundless interest in the welfare of humanity generally. Who can imagine that if Theodore Roosevelt had vegetated in the money-making sphere of his New York Knickerbocker circle, in which he was cradled in comfort and affluence, he would have been the power for good that he is? Mr. and Mrs. Roosevelt were married in London, and they know it as well as they do Washington. Oyster Bay and Nevada, Cuba and Oregon, are equally familiar to this distinguished American, who admirably represents the national tendency to see the world and to study it sympathetically.

Tolstoy in his old age stays at Moscow or at Yasnaia Poliana, but in his younger days he was a great roamer, and if anyone wonders at the enormous influence of Maxim

Gorky, let it be understood that this new genius of literary Russia has spent his whole time in the most romantic wanderings in his vast fatherland. George Meredith, our greatest living novelist, was, as long as his strength allowed, an ardent traveller and pedestrian. Rudyard Kipling, too, owes much of his success to his travels throughout our Empire.

Travel Essential to Culture. Culture without travel is largely a failure. It is irreparably defective in certain directions. The history of the Popes is a lurid illustration of this principle. Some of the Pontiffs have been men of real genius. The late Pope was reckoned the finest Latin scholar in the world. He could write Latin poetry equal to that of Horace himself. But even the most charitable of his own partisans could not pronounce Leo XIII. other than the narrowest of reactionaries. He spent long years in the seclusion of the Vatican. How mighty would be the influence of a Pontiff who could traverse Christendom! The power of the Bishops in Anglican, Roman, and Greek communions depends to a very great extent on the manner in which they see this and that part of their Sees. The late Archbishop of Canterbury, in the days when he was Bishop of Exeter, gained extraordinary personal sympathy amongst the farmers of his great diocese through his constant journeys in his diocese and his zealous interest in their affairs. Christianity began with travel, and it can be propagated in no other way.

Simplicity in Travel. Simplicity is one of the essential conditions of real enjoyment and profit for the traveller. The tourist who knows nothing of the simple life must miss many opportunities of the most desirable kind for making acquaintance with life in its most varied and interesting aspects. It is true that not many of us may feel disposed to emulate the example of Oliver Goldsmith, who allowed the want of means for providing comforts to constitute no impediment to his passion for wandering. He absolutely revelled in the simple life. When his funds were exhausted in Dublin he wandered on to Cork, where, when he was in great distress, a handful of peas was given him by a girl at a wake, the flavour of which remained for ever sweet in his memory. Few men so intimately blended the pleasures of the simple life with the most romantic modes of travel. Goldsmith wandered over wide districts of Europe on foot, scantily provided as to purse and wardrobe, but rich in his kindly nature and his wonder-working flute. Travel is peculiarly adapted to the cultivation of simplicity. It is best enjoyed by those who love "plain living and high thinking." Byron and Shelley*well understood this. The former enjoyed nothing better in his strange career than his sojourn amongst the monks of the Armenian Convent on the Venetian Lagoon for six months, while he studied their language; unless it was the series of his wanderings in wildest Greece, where he revelled in the rough mountain life of the peasants battling for independence.

Untrammelled Travel. We have known the luxury of going over the Dovre Fjeld without any impedimenta beyond a tiny parcel, for who could roam about that magnificent wilderness near the Arctic with the baggage which some tourists seem to think indispensable everywhere? We have journeyed many thousands of miles awheel carrying all our baggage on our bicycle. "Through Norway with a Knapsack," as Williams's charming volume is entitled, suggests one of the ideal methods of enjoying life under the auspices of pure, exhilarating air and of scenery of unspeakable enchantment; while R. L. Stevenson's "Travels With a Donkey" and "An Inland Voyage" are almost lyrical in praise of the simple life in travel.

Travel teaches us that many of the artificial trammels of civilisation are purely superficial and negligible quantities. Every winter explorers like Professors Petrie and Sayce go back from Oxford and London to the East, and spend months in company with the poor native fellahin in Egypt or the nomad tribes of Arabia, leaving the luxuries of the West behind, and revelling in the discoveries that reward their quest. The simple life is being lived by a larger number of people than is generally supposed, but those who observe the very simplest conditions are the great travellers. It is the freedom from the complications and the needless accessories of ordinary home life, evidenced on every page of such records, which gives an indefinable charm to books like those of the late John MacGregor, "The Rob Roy on the Jordan," "The Rob Roy in the Baltic," etc. And from Du Chaillu, in his "Land of the Midnight Sun," many a reader has been set longing for an experience of a holiday among the Scandinavian "saeters," where simplicity is the rule of happy life in fellowship with Nature in her most charming moods.

The Faculties of Enjoyment. We can the better comprehend the utility of travel when we reflect on the measure in which it develops those faculties of purest enjoyment which otherwise may lie altogether dormant. There are perceptive capacities in the human soul which cannot be exercised subjectively, but must have opportunity of objective observation. Nature calls us to admire the infinite variety she has to show. She constantly changes the diorama. But harmony prevails everywhere. Mountains bathe their feet in the depths of crystalline lakes. Artists are captivated by the blending of the most contrasted scenes of sublimity and tenderness in Tyrol and the Dolomites, in the black lava fields of Sicily and the vineyards caressing them round the vast base of Etna. Sympathy with life is seen even on the edge of the great ice-pack of Amsterdam Island, for seals sport playfully in the savage waste. No two scenes are alike. The world only tires us if we stagnate in one spot. Said a gentleman living in one of the most beautiful districts of Kent, "All the prospects round here are lovely, but I know them so well!" The longing for change of scene is wonderfully responded to if we will go forth occasionally from accustomed haunts.

"Men love the tale of a traveller who has his eyes wide open," says a recent writer; and this is true, for in almost any company a guest is more than welcome who has seen something that perhaps others have not. People are hungry for freshness and eager for novel information. Those who have been denied opportunities are often very grateful to the traveller who will take the trouble to recite some of his experiences. And members of the younger generation are continually coming up with aspirations for travel; these are specially anxious to be directed and advised. Nothing is more delightful than the reciprocity of feeling promoted when strangers happen to meet who can compare notes of travel. They become friends offhand, and many desirable relationships are thus formed.

The Utilitarian Side of Travel. This is a large subject, which can here only be lightly touched upon. In the Middle Ages thousands of young artists and of candidates for positions in the various learned professions took long and serious tours. Many still do so. But the practice is not anything like as general as it should be. Many people have with great subsequent profit travelled for the sake not only of enjoying a pleasure trip, but also with the view of taking in fresh observations in respect to architecture and building. A young builder visited America and came home with a stock of new practical notions which he proceeded most successfully to apply. Indeed, the professional bearing of travel and its industrial advantages is altogether inestimable. Vivid illustrations in this direction have recently been supplied by the Japanese. Quietly and unobtrusively during the last two decades thousands of young men from Japan have been visiting all the great countries of the West. The results of their keen observation have been stupendous.

An American admiral was recently invited, while his squadron was in Japanese waters, to dine on board the flagship of a Japanese admiral. As soon as the American was seated in the cabin the host rose quickly, flung a napkin over his shoulder, and said, "Do you know me, captain?" The guest started in astonishment, for he at once recognised his former Japanese servant, who had faithfully attended him for a considerable period in American waters when he was a captain. During that period the young man from the Far East had been quietly taking in a valuable stock of knowledge which he had not neglected to apply for the benefit of his own nation.

A singular instance of the great value of travel in the educational sense occurred in the experience of the famous James Nasmyth, the inventor of the steam-hammer. His original drawings of his invention were approved by some steamship builders, but were for a time laid aside. During Nasmyth's absence at one season from the foundry, two visiting French engineers saw the sketches. Two years later the inventor happened, during a Continental trip, to visit the great Creuzot works. Observing an engine crank which could not have been forged by the old kind of hammer, he asked how the work had been done. "This crank was forged by your steam hammer," was the reply. The French engineers proceeded to show the Englishman the hammer they had built from his plans. He was delighted, and on returning home constructed a hammer for himself, soon managed to interest the British Government, and secured large orders.

How Travel Aids Study. Finally, it must be obvious to every thinking mind that travel is unrivalled in its tendency to increase our geographical knowledge, and to fix the mind accurately in the mastery of topographical features. All who have travelled much are familiar with a very singular phenomenon. In the course of a journey we may happen to visit a spot that we had never previously heard of, and are delighted to have discovered it, on account of unexpected features of interest, beauty, and attractiveness. And, to our astonishment, very likely, after returning home and settling down, we come across references to that same place in newspapers, or magazine articles, or books. The truth is, of course, that such allusions would pass altogether unnoticed but for the fact that we had just become familiar with the obscure locality, and so our attention is naturally drawn to what would have been entirely disregarded but for this acquaintance. Travel invests geographical study with living charm and inexhaustible interest, making it altogether another science than the mere collection of abstractions presented to the non-travelled mind. It also greatly enhances the pleasure and profit of our ordinary reading, and an instance of this from our own recent experience will illustrate the point.

Travel and Book-reading. Happening, by the merest chance, to take up Thackeray's "Henry Esmond" during a resting holiday in Scotland, and thus to re-read it after many years, our interest in the story was vastly increased when we discovered, as we proceeded with it, that with hardly an exception we had visited the scenes of Marlborough's battles in the Low Countries, and had that very summer spent some days in the little-known Alsatian town of Barr, which is mentioned several times in the story in connection with the movements of the Pretender. Indeed, we incline to think it is better to read of places *after* one has visited them than *before*; at all events, better to read of them in greater detail after we have familiarised ourselves with the actual scenes. And all who have travelled agree that the law of mental association works with delightful effect after journeys and voyages near or far. For a picture or a description of scenes we have visited will call up whole chapters of our happiest experiences. The mere guide-book without the journey is the dry letter that kills interest; the journey itself is the spirit, the meaning, the substance, the intention of things, because it brings us in contact with life in all its interesting manifestations.

To be continued

FLEECES AND FIBRES OF WOOL

THE MICRO-PHOTOGRAPHS OF THE FIBRES ARE SEVENTY TIMES MAGNIFIED

condition. At the end of the feeding season, when the lambs are three months old, the farm hands gather to the washing. Three long troughs are filled, one with cleansing dip, one with a weaker solution, and the other with clean water. The sheep to be washed will have been penned the night before. In the early morning begins a long day of arduous toil for the shepherds and their helpers. One after the other, the sheep, bleating, struggling, butting, kicking, are soused, scrubbed and washed in the troughs, and then fly off up the fields, shining with a glittering coat. It is considered a wise practice to let two or three days elapse between washing and shearing, because the yolk, dissolved in the soapy dip, gets time to renew itself.

The question "What is yolk?" naturally occurs to the reader, and it is worth attention. Like all animal fibres, wool has a vital function to perform. It is tubular, containing fatty and other matters exuded from the skin. These matters are called, collectively, yolk, and form a considerable proportion of the weight of wool. An eminent chemist has analysed wool, with this result:

Earthy Substance	26·06
Suint	32·74
Fatty Matter	8·57
Earthy Matter fixed by grease	1·40
Wool	31·23
	100·00

It will be seen that yolk is an important matter. When the yolk supply is small the fibre is harsh; without it, the central tube, being empty, collapses, and the fibre splits.

Within three days after the dipping operation the flock is gathered again. All along the field sheds are erected, and within them long benches. At each bench stands a shearer and his assistant, the former holding in his hand a large pair of shears. The sheep is brought, and turned on the bench, and while it is held firmly, the shearer clips. His work demands no little skill. The skin must not be injured, or blood will smear the fleece; the wool requires to be cut evenly, or the staple will be irregular; and the fleece should come off whole. The work goes on with

"the loud-clapping shears,
While ever and anon, to his shorn peers,
A ram goes bleating."

Varieties of Wool. There are at present more than a hundred kinds of wool on the market, and the manufacturer is frequently embarrassed by the wealth of choice. Practical men, however, classify several kinds under one head, and so spare themselves needless worry. For instance, it is quite well understood that Australia sends wool from six states, differing in climate and soil; but the wool appears on the market as one class, with corresponding sub-divisions arranged

TABLE OF VARIETIES OF WOOL PRINCIPALLY USED IN THE WOOL TRADES

Country.	Breed.	Quality.	Length of Staple	Average Weight of Fleece.	Yarn Number	Fabrics.
Spain	Merino	Fine	Short	5 lbs.	50-130	Broadcloths, worsteds, ladies' dress cloths, and all the highest classes of wool fabrics.
Saxony	.. and cross-bred	Very fine	..	—	10-180	
Silesia	.. ..	Finest	..	—	100-240	
Australia	Merino, cross with Leicester and Southdown	Very fine	—	8 lbs.	80-150	
United Kingdom	Lincoln	Good	Long	8-9 lbs.	40-90	Imitation alpacas, lustre, and worsteds
..	Leicester	Fine to coarse	..	7-9 lbs.	20-70	Worsteds and hosiery yarns
..	Romney Marsh	Medium	..	7 lbs.	30-50	Woollens and carpets.
..	Southdown	Fine	Short	3-4 lbs.	40-80	Light dress cloths
..	Dorset	Medium	..	24 lbs.	20-40	Livery cloths, woollens
..	Cheviot	..	Medium	3-4 lbs.	30-50	Tweeds, woollens, heavy dress cloths.
..	Cotswold	..	Long	7-8 lbs	50-70	Cords, worsteds, serges.
..	Blackface	Coarse and strong	Medium	--	10-40	Blankets, carpets, etc.
..	Highland	Coarse and strong	..	—	10-50	Blankets, carpets, etc.
France (South)	Merino & Rousillon cross	Soft, fine	Long	9 lbs.	170-180	Dress goods, merinos, cashmeres.
.. (North)	Cross-breds, various	Medium	Short	-	20-95	Woollens
Algeria	Native sheep	Inferior, but soft	..	-	10-70	Felts, blankets, rugs.
Turkey	Angora	Very fine	Long	-	Finest yarn	Fine cloths.
..	Native breed	Coarse	Short	—	Low counts	Felts and coarse wools.
East Indies	Various breeds	Generally coarse	Short	--	Coarse counts	Carpets, felts.
..	Hooniah	Fine	Long	—	3-80	Ladies' dress goods, shawls.
Russia	Odessa	Fine	Short	—		Worsteds
..	Merino	Very fine	Medium	-	75-18	Broadcloths and serges.
..	Astrakhan	Special character	Short			Astrakhan cloth.
South Africa	Fat-tailed	Various classes	—	--	—	Worsteds, alpacas, woollens.
..	Merino					
..	Angora					
South America	Imported European breeds	Good, but dirty	Medium		90-200	English fine cloths.

not in accordance with geographical areas, but variations in quality. All the wools of Australia and New Zealand have peculiar qualities that distinguish them as a class. Similarly, though some varieties of Leicester wool may closely resemble those of Lincolnshire, the skilled wool-buyer can recognise differences.

Classification. After all, we are users of wool, not students of sheep pedigrees. We can leave aside nice questions of variety and breed, and lend our attention to the useful qualities of the fibre. In old books, it is said that wools are divisible into two classes, carding and combing, the latter being long and the former short in staple. But we find in practice that this classification helps very little. The very finest combing wools are classified as short, and many wools of medium length are quite unsuitable for combing. *We must take a wider standard of comparison, and* try to define what is technically described as the *service* of the various wools. This can be done best by giving the averages of these qualities—(1) Length of staple, (2) Weight of fleece, (3) Yarn number, (4) Use.

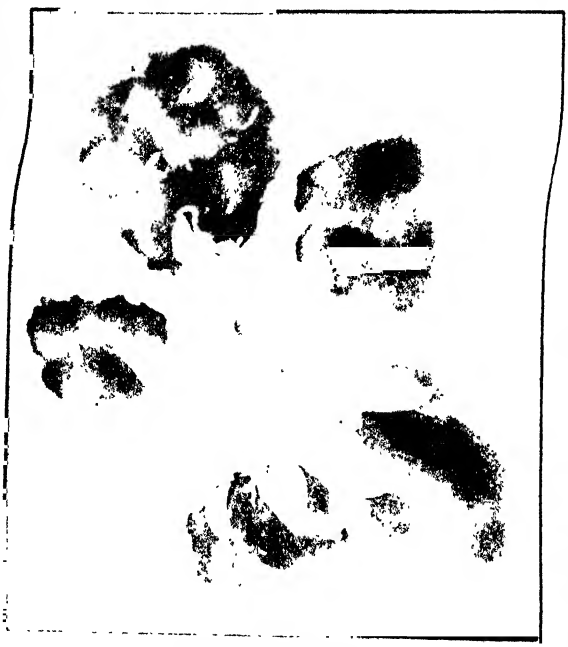
Qualities. Generally speaking, the qualities of fibre most desired are—(1) Length, (2) Fineness, (3) Soundness, (4) Colour or lustre, (5) Elasticity, (6) Softness. Fleeces are classified according to the degree in which they possess these qualities, as finest, very fine, fine, good, medium, coarse.

In the trade much confusion has arisen by the different methods of measuring the counts of yarns in various localities. When we deal with yarns, these differences will be thoroughly considered. The system coming generally into use is that upon which worsted yarns have been calculated. It is simple and easily understood. A hank is 560 yards of yarn, and the number of hanks in the pound avoirdupois gives the number of the yarn. If there are 20 hanks in the pound, the yarn is number 20; if there are 60 hanks to the pound, the yarn is number 60, or 60's. Upon this plain standard we have based our calculations.

COTTON

The Cotton Plant. Cotton fibre is derived from a plant to be found growing wild in nearly every tropical and sub-tropical country on the surface of the earth. Our globe has a cotton belt extending between the 40th parallels of latitude. Growing in many different climates and soils, the *Gossypium*, as botanists name it, has developed local peculiarities; but in every region the seeds of the plant are enveloped in a fluffy fibre, designed, it seems, to assist in protecting and disseminating the seeds. Early in his terrestrial career man appropriated this fibre, extracted the contained seeds, and used the clothing of the plant germs for the covering of his own nakedness.

Taken by itself, a cotton plant seems rather an unpromising producer of clothes. The five tufts of fibre springing from the five-celled capsule appeal *more to the sense of beauty than to the perception of utility.* But multiply the capsule a millionfold, let these capsules spread their down on the herbage around, gathering in heaps like drifts of snow, and then will be perceived the munificence of the gift which tropical nature offers man in cotton. Wherever the cotton plant grows there has been, at one time or another, a cotton industry. Historians used to tell us that cotton manufacture began in India, in Egypt, in China, or elsewhere, but we cannot affirm with certainty that cotton manufacture originated in any particular locality.



THE COTTON PLANT

The Cotton of the New World. For the root of our modern cotton industry we have to look to India, where cotton has been grown, spun, and woven from time beyond knowledge. Curiously enough, the discovery of the cotton plant growing on one of the West Indian islands confirmed Columbus in the idea that he had reached India by a western route. The great navigator was familiar with cotton, and he saw that the plant growing on the West India Islands gave a longer, finer staple than the cotton plant of East India. The Spaniards, taught centuries before the secret of cotton spinning and weaving by the Moorish invaders, sought to

utilise the resources of the continent given them by the hand of fortune, and cotton manufacture became an important industry at Valladolid and elsewhere. The ambition of Spain, however, to excel the wondrous cotton prints which her rival Portugal imported from Calicut, proved futile. Another and stronger nation, even then pushing along the path of empire, was to accomplish the task.

Not content with wresting from Spain the North American continent, the English went east, and established themselves on the vast peninsula of India. In 1600 Elizabeth granted a charter to a company of merchant adventurers which afterwards grew to imperial power, under the name of the East India Company. From the charter of "John Company," we learn that one of the principal objects of the incorporation was to trade in muslins and calicoes. How the Company rose to power, annexed territories, and formed the great Indian Empire, history records, and the stirring story has often been told; but the cotton trade of this country can hardly be described without some reference to the East India Company. It was in this industry that *the eastern and western sections of the British Empire developed rival and apparently antagonistic interests.*

The Industry of Lancashire. To many it must be a matter of wonder, if not mystery, that nearly the whole of the cotton industry of England is concentrated in the county of Lancashire. Trades tend to centralise in the particular area which affords most economic advantages. Seemingly accidental, the location of any industry generally finds explanation on economic, and sometimes on historical, grounds. For the pre-eminence of Lancashire in the cotton trade, neither the economic nor the historical reasons hold good. India manufactured cotton thousands of years before Manchester was founded, and it has the raw material at hand, while Lancashire must transport it thousands of miles. Cotton was spun and grown in Florida in 1536, while Manchester was learning to weave fustians, and now the cotton wool of Florida is spun in Lancashire, to be returned, in spite of a tariff wall, to America in the shape of cloths.

The explanation lies in the peculiar physiographic character of Lancashire. Cotton is a very delicate fibre and cannot be successfully spun under all conditions. Three special conditions the cotton spinner requires—an equable and temperate climate, a humid atmosphere, and a copious water supply. Bounded on the west by the sea, Lancashire is seldom visited by severe frosts or hard winters, while on the eastern side high hills form a watershed which provides abundance of water all the year round. The most important and most secret factor, however, is the clay sub-soil of the county. On this clay bed beneath the soil the rain-water lies, and evaporates as the temperature of the upper air rises, rendering the air moist and humid. In a warm, dry atmosphere the fibres become brittle and refuse to combine; in a wet condition cotton collapses and sticks. The medium between dampness and dryness is the ideal. The humidity of Lancashire's atmosphere has made that county the greatest cotton-spinning centre in the world.

As far back as the seventeenth century Manchester people seem to have been attracted by cotton, and the modern development of the cotton industry dates from the beginning of the eighteenth century. Up till 1735 cotton was wholly spun by hand, the primitive method practised for centuries in the lands where cotton is grown. About 1735 it occurred to a man named Wyatt that cotton might be spun by drawing it through rollers.

Introduction of Machinery. Let us explain. The raw cotton, as it came from the West Indies and Smyrna, was a mass of dirty fibres. The cotton manufacturer first opened it out and shook it free from dirt by hand, carefully picking out all the stray seeds, dirt, fragments of leaves and other vegetable matter. Next, he took two flat pieces of wood filled with spikes and drew the cotton from the one to the other, carding it out into a fine fleecy condition. Next, the cardings were fixed on a wooden tool set above a spinning-wheel. Most people have seen a spinning-wheel. The wheel, it may be explained, does not spin; its function is simply to drive the spindle on which the spun yarn is wound. The spinning agent is the hand of the spinner. A thin strand of fibre is carefully drawn off the carding and wound on the wheel-driven spool. With one hand the spinner drives the wheel, and with the other carefully twines and draws out to slender fineness the fibre. In that primitive instrument lie all the principles of cotton spinning. The greatest water-wheel in the world is simply a larger brother of the small hand wheel, and performs precisely the same office.

Wyatt's machine substituted a series of drawing rollers mechanically driven for the fingers of the spinner. The contrivance was not a great success; but it pointed the way to other inventors. Richard Hargreaves hit on a different idea for spinning and drawing out the cotton threads by mechanical means. He devised a frame, on one side of which he placed the cotton wool, and on the other the yarn bobbin, starting the two parts close together and drawing them apart, slowly and with regulated motion, thinning out the thread. This was the famous spinning Jenny, popularly ascribed to Arkwright. Hargreaves made his machine practical in 1767, and it was widely adopted by cotton manufacturers, without yielding much profit to the inventor.

Organiser of the Cotton Factory. About the same time Richard Arkwright was working at his spinning machine, developing Wyatt's idea, and in 1769 he took out a patent. To Arkwright belongs the merit of putting cotton spinning on a scientific basis. His drawing machine was contrived on definite lines, the draught being properly regulated, so that the spinner knew exactly what weight of thread he could get into a given length or *vice versâ*. The inventor calculated that if he speeded his

drawing rollers to double the number of revolutions of his delivery rollers, the yarn would be drawn out to twice the length. Similarly, if the winding apparatus ran at double the speed of the drawing rollers, the thread would be lengthened by that proportion. In 1780 Samuel Crompton, another inventor, combined the ideas of Hargreaves and Arkwright in a contrivance he named the spinning mule, and gave to cotton manufacturers the machine which, in its improved form, has enabled them to produce mechanically threads finer than the spider's web, and more regular than the most delicate products of the patient spinners of Dacca. Though his invention had not the valuable properties of Crompton's mule, Arkwright has other claims to fame in cotton manufacture. He improved the machine carder, ranged the drawing and spinning machines in regular gradation—in short, the ex-barber organised the cotton factory.

Weaving Machinery. While cotton spinning was developing by mechanical invention, the weaving process remained almost stationary. The main end of cotton spinning is cloth manufacture, and when the secondary process lags far behind the first, the loss is great both to the industry and to the consumer of the product. The first result of increasing the rapidity of cotton spinning was increase in the number of weavers employed, not only in this country, but also in India. Between 1770 and 1820 the Indian import of British cotton yarns was enormous; but in later years cotton cloths were sent instead, and the Hindu weavers died off by the thousand. In this country, about the year 1800 the cotton weaving trade employed 250,000 weavers, but the invention of the power loom took the bread out of the mouths of at least two-thirds of that number.

The power loom was invented by the Rev. John Cartwright in 1785. Cartwright was a clergyman, and became interested in weaving from a purely academic point of view. He set about inventing the power-loom to prove to some friend his contention that it could be done. The loom as first invented was quite useless; but the persevering inventor corrected his errors, and in the end produced a serviceable power-loom. For some years the introduction of the power-loom was slow; but about 1812 so many factories began to use Cartwright's invention that thousands of weavers were thrown idle, and caused riots in many Lancashire towns. The power-loom was necessary, however, to the efficiency of the cotton industry, and though we may hope that one day improvements and labour-saving inventions will be introduced in a manner involving less suffering to the workers, we must recognise the benefits which have accrued to mankind from the power-loom.

At first it seemed to everybody that the power-loom would be confined to the weaving of plain cloths; the machine could only go on repeating with blind regularity a few simple motions; pattern and fancy weaving was yet the safe preserve of the hand-loom weaver. Certain Scottish and English manufacturers, however, did not share the common opinion of the power-loom, and proceeded, early in the nineteenth century, to utilise it for the highest-class of fancy weaves, mounting the power-looms with ingenious and efficient pattern-forming appliances by automatic change of shuttle; by supplementary warps, and other contrivances, patterns of the most elaborate kind were woven, and when the jacquard apparatus came to give the warp a mobility equal to that of the weft, the circle was completed, and the power-loom became an instrument of art far surpassing the finest hand-loom.

The Thread Industry. While the English spinners were intent on bringing their yarns to the loom, the Dutch cotton manufacturers were finding another market in the production of thread for the lace workers and makers of garments. Up to the middle of the eighteenth century the Dutch had it all their own way in the thread trade; but at that time a noble lady, named Shaw, living in Renfrewshire, near Paisley, began to manufacture cotton thread, for both her own domestic use and for that of her friends. The lady of Bargerran, as she was pleased to be called, developed quite a large trade, and her near neighbours, with that commercial keenness which has since characterised the thread manufacturer, began to compete with Lady Shaw in a rather dishonest manner. Of course, there were honest thread-makers in Paisley, and the honest and dishonest between them had built up quite a respectably-sized business by the year 1789. At that time the thread trade employed over 4,000 people in Paisley alone. Having this start, the Scottish thread-makers were enabled to take advantage of every new improvement in the cotton-manufacturing process, and almost before English spinners were aware of it their northern rivals had established a practical monopoly in the thread trade. Here and there, in Lancashire and Nottingham, thread manufacturers had quietly established themselves, and gradually came into the larger markets of the world, to compete with the great Paisley concerns. For more than sixty years the commercial battle was waged. In 1896 the Paisley firms amalgamated, with a capital of £10,000,000, and as a counter-move, the English firms united under the name of the English Sewing Thread Company. But victory was with the Scots, who had already taken precautions. They held a large interest in the syndicate organised to oppose them. The English company was therefore like a besieged city with the enemy in the citadel. Terms were arranged, and the sewing-thread manufacture passed into the hands of monopoly.

Lace Making. The latest development of the cotton trade was the lace factory. One of the first European industries to make large demands for cotton yarn and to stimulate cotton spinning, lace-making was the last to submit to factory centralisation. For hundreds of years lace was made by hand. The first form of it was a kind of crochet-work, wrought by a needle, and therefore named point lace or guipure. In 1561 a Dutch lady made an

imitation lace by pinning the pattern down on a cushion, and plaiting threads over it in the form desired. This became known as pillow lace and developed on lines of its own. Lace-making is essentially an artistic home industry, and it might have remained outside the circle of machine industry but for the invention of a lace loom by a man named Hammond in 1768. The idea was taken up by Heathcote, a Nottingham hosier, who made a practical machine; Morley, founder of the great firm of Morley & Co., made further improvements, taking out patents in 1811 and 1824. In the latter year two other Nottingham firms, Lever & Turton and Clark & Mari, took out patents for improvements in the lace loom. Like the Paisley thread-makers, the Nottingham lace manufacturers were well on their way before the other members of the cotton trade had realised that a vast market had been opened up and was rapidly being monopolised. Nottingham has retained the lead it thus gained. The lace loom is like no other kind of weaving machine; the warp-beam is under the feet, and the cloth-beam over the head of the weaver; no shuttle flies across the warp, but each thread of the warp has a shuttle all to itself; the lifting leaves of the healds are absent, and instead strong fingers, directed by the jacquard apparatus, pull aside the threads of the warp; the rhythmic beat of lathe and heald and shuttle, so musical and suggestive of pleasant harmony, has given place to a louder, harsher, more powerful sound. Iron and steel and brass, the lace loom is a gigantic tool of titanic power devoted to the production of the lightest, filmiest of fabrics; the force of steam, of electricity, the strength of metal forged and moulded, the energy called into action by powers centripetal, centrifugal, and lever—all combine to create a filmy fabric of flowers and wreaths.

Cotton Trade of Europe. Before the discovery of America European cotton industry depended almost wholly on the Levant for raw material. Both demand and supply were small. With the discovery of the West Indies and America, however, a great change came. Cotton of the finest quality was to be had for the taking in those wonderful islands of the West. Spaniards, Dutch, and English shipped cotton from Cuba, Jamaica, Barbadoes, and the other West Indian Islands, in reckless greed, bringing to an industry only beginning a plethora of raw material. Thus gifted and endowed, the cotton trade of Europe took its start. The wool-spinners of Valladolid, Haarlem, Tours, Lancashire, and Yorkshire, finding a cheap spinning material at hand, entered into cotton production, and created a permanent market for cotton fibre. During the troublous sixteenth and seventeenth centuries the cotton industry, as the youngest and least important of the industrial enterprises then existing, suffered most, and grew but slowly, like a weakly child born in slumdom. Not until the English had served themselves heirs of Spain's dying empire, and taken possession of the West Indian Islands, was the cotton industry firmly established on a sure supply of raw material, and the trade enabled to grow with healthy vigour.

As the spinners of Lancashire attained pre-eminence in the trade, they began to export cotton cloths to India, competing in the bazaars with native cloths. Finding that the Western invaders could sell them manufactured cloth cheaper than they could make it, the Hindu weaver-cultivators gave up spinning and weaving, devoted themselves to cotton culture, and sold the fibre in exchange for the finished article. So another source of supply was provided for the cotton industry. Lancashire received its first consignment of Indian raw cotton in 1783, the amount being 60,000 lbs.

North American Cotton. About 1530 the Spaniards began to settle on the mainland of the American continent, founding the state which has been named Florida. While their countrymen were rendering desolate the Antilles, these settlers took a more sensible way of enriching themselves. In 1536 the colonists of Florida made their slaves raise cotton from the seed of the Barbadoes cotton plant. Following close on the heels of their rivals, the English settled in Florida, and soon dominated the colony. With characteristic energy they took up the cultivation of cotton, utilising the islands lying along the sea-board of Georgia, separated from the mainland by salt marshes. Climate and soil favoured the plantations of cotton. The product was a fibre of superior quality, longer, finer, silkier, than any cotton seen in the world before. For two hundred and fifty years the cultivation of cotton spread over the American continent, but always for home consumption.

In 1770 the colonists, hearing of the market for raw cotton springing up in England, determined to have a share. Samples of Sea-island cotton were sent over to Lancashire, but the staple was not found suitable for use, and no business resulted. After the War of Independence, the planters took some time to settle down into regular industry; but in 1790 another attempt was made on the Lancashire cotton market. This time the samples of Sea-island cotton were placed in the hands of Robert Owen, afterwards famous as a social reformer, but then known as the ablest cotton spinner in the trade, and a young man of singular honesty. Owen found that the cotton produced a yarn of fine quality, but the colour was so bad that he disposed of the yarn, for a mere trifle, to a Scottish muslin manufacturer named Craig. Within two months Mr. Craig returned to Owen, offering to buy as much of the yarn as the spinner could supply. Very much surprised, Owen made enquiry, and learned that by bleaching Craig had brought the yarn to a fine purity of colour. With his characteristic candour Owen laid the facts before his employer and the manufacturers associated with him. The effect of his report was immediate. In 1791 the importation of American cotton to this country amounted to 189,361 lbs. The American cotton trade, begun in this haphazard manner, has become one of the most important and established factors in the history of the modern world.

COMPOUND QUANTITIES

Reduction of Compound to Simple Quantities, and of Simple to Compound Quantities. First Four Rules applied to Compound Quantities.

By HERBERT J. ALLPORT

34. We have defined a unit quantity to be a quantity with which we compare other quantities of the same kind, for the purpose of measuring their magnitude. Evidently, then, different kinds of quantities, such as money and time, must each have their own unit. But it is not always convenient to use the *same* unit, even when measuring quantities of the same kind. For instance, we speak of the distance between two towns as so many *miles*, and of a piece of string as measuring so many *inches*. It is therefore necessary to make lists, or *Tables*, showing the connection between the unit and its various multiples and subdivisions.

TABLES

35. The following tables are in general use in England at the present time.

MONEY.

The unit of English money is the pound sterling (£1)

4 farthings	= 1 penny (1*d.*)
12 pence	= 1 shilling (1*s.*)
20 shillings	= 1 pound (£1)

¼*d.*, ½*d.*, ¾*d.* are used to denote 1 farthing, 2 farthings, 3 farthings

TIME.

The unit of time is 1 day (a "mean solar day").

60 seconds (sec.)	= 1 minute (1 min.)
60 minutes	= 1 hour (1 hr.)
24 hours	= 1 day
7 days	= 1 week
365 days	= 1 year (1 yr.)
366 days	= 1 leap year

[See note on the Calendar.]

AVOIRDUPOIS WEIGHT.

For weighing common goods. The unit is the pound weight, 1 lb.

16 drams (drs.)	= 1 ounce (1 oz.)
16 ounces	= 1 pound (1 lb.)
28 pounds	= 1 quarter (1 qr.)
4 quarters	= 1 hundredweight (1 cwt.)
20 hundredweight	= 1 ton
14 pounds	= 1 stone

TROY WEIGHT.

For weighing precious metals. Troy weight is now illegal, except the ounce.

24 grains (grs.)	= 1 pennyweight (1 dwt.)
20 pennyweights	= 1 ounce (1 oz.)
12 ounces	= 1 pound (1 lb.)

APOTHECARIES' WEIGHT.

For weighing drugs.

20 grains	= 1 scruple (1 scr. or 1 ℈)
3 scruples	= 1 drachm (1 dr. or 1 ʒ)
8 drachms	= 1 ounce (1 oz. or 1 ℥)

Note: The grain Troy is the same as the grain Apothecaries': and 7000 grains = 1 lb. Avoirdupois.

LINEAR MEASURE.

The unit is the yard. 1 yd.

12 inches (ins.)	= 1 foot (1 ft.)
3 feet	= 1 yard (1 yd.)
5½ yards	= 1 pole (1 po.), rod, or perch
40 poles	= 1 furlong (1 fur.)
8 furlongs	= 1 mile (1 mi.)
3 miles	= 1 league (1 lea.)

1 chain, of 100 links = 22 yards, so that
10 chains = 1 furlong, and
80 chains, or 1760 yds. = 1 mi.

SQUARE MEASURE.

For measuring area. The unit is the square foot.

144 square inches (sq. ins.)	= 1 square foot (1 sq. ft.)
9 square feet	= 1 square yard (1 sq. yd.)
30¼ square yards	= 1 square pole (1 sq. po.)
40 square poles	= 1 rood (1 ro.)
4 roods	= 1 acre (1 ac.)
640 acres	= 1 square mile

10 square chains, or 4840 sq. yds. = 1 acre

CUBIC MEASURE.

For measuring volume, or solidity. The unit is the cubic foot.

1728 cubic inches (cu. ins.)	= 1 cubic foot (1 cu. ft.)
27 cubic feet	= 1 cubic yard (1 cu. yd.)

MEASURE OF CAPACITY

The unit is the gallon.

4 gills	= 1 pint (1 pt.)
2 pints	= 1 quart (1 qt.)
4 quarts	= 1 gallon (1 gall.)
2 gallons	= 1 peck (1 pk.)
4 pecks	= 1 bushel (1 bush.)
8 bushels	= 1 quarter (1 qr.)

36. Note on the Calendar. The mean solar day, i.e. the interval occupied by one revolution of the earth about its axis, is the unit of time. The mean tropical year, i.e. the interval between one vernal equinox and the next, is equal to 365·2422... solar days.

In the time of Julius Cæsar this number was not so accurately known. It was then considered to be 365·25 days. Thus, 4 years = 365·25 × days = (365 × 4) + 1. Hence, once in 4 years, an extra day was put in the calendar. The Roman year began in March [hence, *September*, the

seventh month, etc.), so the day was put on to the end of the year, making 29 days in February.

But, as the length of the year became more accurately known, it was seen that 1 extra day in 4 years was too much. Hence, in 1582, Pope Gregory ordered that the extra day should be omitted 3 times in 400 years.

Therefore, if the number which represents any particular year is exactly divisible by 4, that year is a leap year; except, *in those years represented by complete hundreds, such as* 1600, 1900, *etc., only those are leap years in which the number of hundreds is divisible by* 4.

For example, 1600 was leap year, since 16 is divisible by 4. 1900 was *not* leap year, since 19 is not divisible by 4.

The *object* of this arrangement is to keep the seasons of the year in the same place in the calendar. The Church required Easter to fall always in the same season.

It was not until 1752 that this *Gregorian Correction* was adopted in England. In that year eleven days were omitted from the calendar, Sept 3 to Sept 13 inclusive, being the days which should have been omitted in the years 300, 500, 600, 700, 900, 1000, 1100, 1300, 1400, 1500, 1700.

REDUCTION

37. So far, we have only dealt with *simple* quantities, *i.e.* quantities expressed in terms of a single unit, such as £33, or 27 tons. A quantity expressed in terms of more than one unit is called a *compound quantity.*

Thus £4 2s 10½d. and 5 yds. 2 ft. 8 ins. are each a compound quantity.

A compound quantity is expressed as a simple quantity, or a simple quantity is expressed as a compound quantity, by the process of Reduction.

38. Reduction of a compound to a simple quantity.

Example 1. Reduce £17 18s. 4½d. to farthings.

```
 £  s. d.
17 18 4½
20
358 s.
 12
4300 d.
   4
17202 far. Ans.
```

Explanation. From the Tables, we know 20s make £1. Therefore £17 = 17 × 20 shillings. Therefore, put the multiplier 20 under the 17. Do the multiplication, and add-in 18s at the same time. This gives 358 shillings.

Next, there are 12 pence in 1 shilling: so, multiply the 358 by 12, and add-in 4d. This gives 4300d. Finally, since there are 4 farthings in 1d., multiply 4300 by 4, and add-in 2 farthings (½d.).

Example 2. Reduce 23 po. 3 yds. 2 ft. to ins.

```
23 po. 3 yds. 2 ft.
 5½
118
 11½
129½ yds.
  3
390½ ft.
 12
4686 ins. Ans.
```

Explanation. 5½ yds. = 1 po. Multiply 23 by 5½, and add-in 3 yds. Thus: five 3's 15, and 3, 18, carry 1; five 2's 10, and 1, 11.

Next, take half of 23 (*i.e.* divide 23 by 2) and put the result under the 118, taking care to begin in the correct place—the tens' place in this case.

Add the two results, giving 129½ yds.

Now, since 3 ft. = 1 yard, multiply by 3, and add-in the 2 ft. Thus: 3 times ½ = 1½, carry 1; three 9's 27, and 1, 28, and 2, 30, carry 3; three 2's 6, and 3, 9, etc.

Similarly, since 12 inches = 1 ft., multiply the last result by 12.

EXAMPLES 3

Reduce to farthings: **1.** £904 1s. 5¾d.; **2.** £48 0s. 11¾d; **3.** £6501 18s 7d.

Reduce to halfpence: **4.** £98 14s. 2d.; **5.** £251 18s. 4½d; **6.** £1000 1s 1½d

Reduce: **7.** £42 5s 6d. to sixpences; **8.** £53 8s. 9d to threepences; **9.** £542 15s. to crowns; **10.** £58 7s 6d to halfcrowns; **11.** £1123 14s to florins. **12.** 1527 guineas to threepences

Reduce to seconds: **13.** 14 hrs. 23 min. 19 sec.; **14.** 5 dys 17 hrs 43 min; **15.** 3 wks 2 dys. 6 hrs.

Reduce to lbs: **16.** 5 tons 17 cwt. 3 qrs; **17.** 15 cwt. 2 qrs. 21 lbs; **18.** 73 tons 19 lbs.

Reduce: **19.** 1 ton 17 cwt. 2 qrs 18 lbs 14 drams to drams; **20.** 14 cwt. 97 lbs 11 oz to ounces

Reduce to inches: **21.** 3 fur. 18 po. 4 yds 9 ins.; **22.** 18 mls 6 fur. 11 po. 2 yds 2 ft; **23.** 1 fur. 187 yds 1 ft.; **24.** 3 mls 943 yds.

Reduce to sq in: **25.** 28 sq yds 8 sq. ft 84 sq in; **26.** 2 ro. 13 po. 19 sq yds. 5 sq ft

Reduce: **27.** 4 acres 1 ro. 23 sq yds. to sq. ft.; **28.** 15 ac 3127 sq yds to sq. yds.; **29.** 5 cu yds. 17 cu ft 1314 cu in. to cu. ins; **30.** 200 cu. yds. to cu ins.; **31.** 3 bush. 2 pks. 1 gall to pints; **32.** 7 qrs. 5 bush 3 pks. to galls.; **33.** 1 gall 3 qts. 1 pt. to pints; **34.** 14 qrs. 4 bush. 1 gall. to quarts.

39. Reduction of a simple quantity to a compound quantity.

Example 1. Reduce 721946 drams to tons.

```
16 { 4 ) 721946 drams.
   { 4 ) 180486 + 2  }
16 { 4 )  45121 oz. + 2 } 10 drs.
   { 4 )  11280 + 1 }
28 { 4 )   2820 lbs. } 1 oz.
   { 7 )    705       }
     4 )    100 qrs. + 5 } 20 lbs.
    20 )      5 cwt.
```

1 ton 5 cwt. 20 lbs. 1 oz. 10 drs. *Ans.*

Explanation. We know 16 drs. make 1 oz. Therefore the no. of oz. in 721946 drs. will be the no. of 16's in 721946.

Hence, divide by 16 (using *factors*). The quotient will be ozs. and the remainder (formed as in Art. 27, Ex. 1.) drams.

Similarly, we divide this quotient by 16 to find the no. of lbs., and so on.

Example 2. Reduce 9241205 sq. ins. to acres.

```
    ⎧12 ) 9241205 sq. ins.
144 ⎨12 )  770100 + 5        ⎫
     9 )    64175 sq. ft.    ⎬ 5 sq. ins.
              7130 sq. yds. 5 sq. ft.
                 4
     ⎧11 )   28520 qr.-yds.
*121 ⎨11 )    2592 + 8       ⎫
    40 )       235 sq. po. + 7 ⎬ 85/4 yds. = 21¼ yds.
     4 )         5 ro. 35 sq. pls.
1 ac. 1 ro. 35 sq. pls. 21 sq. yds. 5 sq. ft. 5 sq. in.
                                    2 sq. ft. 36 sq. in. †
1 ac. 1 ro. 35 sq. pls. 21 sq. yds. 7 sq. ft. 41 sq. in.
                                                   Ans.
```

Explanation. The principle is the same as before. But, on reaching square yards, we find a difficulty in reducing them to sq. poles, since (*) we cannot divide by 30¼. This is overcome by reducing the yards to *quarter* yds., and then dividing by the no. of *quarter*-yds. in a square pole, viz. 121. The remainder is found to be 85 quarter-yds., i.e. 21¼ sq. yds.

† The ¼ yd. is usually expressed in feet and inches, and added to the result in that form.

EXAMPLES 4

Reduce to £ *s.* *d.*: **1.** 50627 farthings; **2.** 79165 halfpence; **3.** 91647 pence; **4.** 14051 threepences; **5.** Fifty thousand farthings; **6.** A million halfpence; **7.** 5217 sixpences; **8.** 30120 halfcrowns.

Reduce to weeks, days, etc.: **9.** 92317 min.; **10.** 842508 secs.; **11.** Two million seconds.

Reduce to tons, cwts., etc.: **12.** 7924357 drs.; **13.** 435840 oz.; **14.** 37064 lbs.; **15.** 15000000 grains.

Reduce to lbs., ozs., etc., Troy: **16.** 24102 grains; **17.** 90700 grains; **18.** 42103 dwts.

Reduce: **19.** 201042 ins. to mls., fur., etc.; **20.** 142857 ft. to mls., yds., etc.; **21.** 345024 links to mls., fur., chains; **22.** 9184203 ins. to leagues, mls., fur., etc.; **23.** 15200548 sq. ins. to acres, roods, etc.; **24.** 201028463 sq. ins. to acres, yds., etc.; **25.** 428571 sq. ft. to acres, roods, etc.; **26.** 19146428 sq. yds. to sq. mls.; **27.** 7895432 cu. ins. to cu. yds.; **28.** 773014 cu. ins. to cu. yds.; **29.** 1920743 pints to bush.; **30.** 841793 galls. to qrs., bush., etc.

40. The processes of Arts. 38 and 39 are combined in such examples as the following:

Example 1. Reduce 14295 halfcrowns to guineas.

```
        14295 halfcrowns.
            5
    2 ) 71475 sixpences.
  ⎧3 ) 35737s. 6d.
21⎨7 ) 11912 + 1   ⎫
        1701 guineas + 5 ⎬ 16s.

1701 guin. 16s. 6d. Ans.
```

Explanation. Both a halfcrown and a guinea contain an exact number of sixpences. Hence, reduce the halfcrowns to sixpences, and then the sixpences to guineas.

Example 2. Reduce 3129 oz. Troy to cwts., etc.

```
         3129 oz.
           20
        62580 dwts.
           24
       250320
       125160
7000 ) 1501920 grs.
  ⎧4 ) 214 lbs. Avoir. 3920 grs.
28⎨7 )  53 + 2  ⎫
    4 )  7 qrs. + 4 ⎬ 18 lbs.
         1 cwt. 3 qrs. 18 lbs. 3920 grs. Ans.
```

Explanation. Reduce Troy weight to grains. Then, 7000 grs. = 1 lb. Avoir. ∴ divide by 7000 (short division). This gives 214 lbs. and 3920 grs. remainder. Reduce lbs. to cwt.

EXAMPLES 5

Reduce: **1.** £1000 to guineas; **2.** 297 threepences to fourpences; **3.** 3570 guineas to halfcrowns; **4.** 591 florins to halfguineas; **5.** 250 lbs. Troy to cwts.; **6.** 1460 chains to poles; **7.** 7240 guineas to crowns; **8.** 1 ton 2 cwt. to lbs., etc., Troy.

COMPOUND ADDITION

41. Compound quantities are added together as in the following examples. The method will be the same whatever system of units we may be using.

Example 1. Add together £17 4*s.* 6*d.*, £9 11*s.* 7¼*d.*, £43 18*s.* 9½*d.*, £4 1*s.* 5¾*d.*

£	*s.*	*d.*
17	4	6
9	11	7¼
43	18	9½
4	1	5¾
£74	16	4½ *Ans.*

Explanation. Write the quantities so that units of the same kind come in vertical columns.

First add the farthings.

Say 3, 4, 6 farthings = 1½*d.* Put down ½*d.*, carry 1*d.* Add the pence, including the 1*d.* carried. 6, 15, 22, 28*d.* = 2*s.* 4*d.* Put down 4*d.*, carry 2*s.* Add the shillings, adding the units' column first, then the tens': 3, 11, 12, 16, 26, 36*s.* = £1 16*s.* Put down 16*s.*, carry £1, and add the £'s as in simple addition.

Example 2. Add together 1 ton 3 cwt. 2 qrs. 17 lbs. 5 drs., 14 cwt. 19 lbs. 3 oz., and 3 tons 5 cwt. 3 qrs. 8 lbs. 14 drs.

tons	cwts.	qrs.	lbs.	oz.	drs.
1	3	2	17	0	5
	14	0	19	3	0
3	5	3	8	0	14
5	3	2	16	4	3 *Ans.*

Say, 14, 19 drs. = 1 oz. 3 drs., carry 1.
4 oz.
8, 17, 24, 34, 44 lbs. = 1 qr. 16 lbs., carry 1.
4, 6 qrs. = 1 cwt. 2 qrs., carry 1.
6, 10, 13, 23 cwt. = 1 ton 3 cwt., carry 1.
4, 5 tons.

COMPOUND SUBTRACTION

42. Compound quantities are subtracted as follows:

Example 1. From £18 4*s*. 2¼*d*. take £11 17*s*. 4½*d*.

£	*s*.	*d*.
18	4	2¼
11	17	4½
£6	6	9¾ *Ans*.

EXPLANATION. Write the smaller quantity under the larger, with units of the same kind in the same column. Then, make the lower line up to the top line, as in Art. 13.

Say, 3 far. and 2 far. = 1¼*d*., carry 1*d*.
1*d*., 5*d*., and 9*d*. = 1*s*. 2*d*., carry 1*s*.
1*s*., 8*s*., and 6*s*. = 14*s*., carry 10*s*.
10*s*., 20*s*. = £1, carry £1
£1, £2, and £6 = £8.

Thus, £6 6*s* 9¾*d*. must be added to £11 17*s*. 4½*d*. to make £18 4*s*. 2¼*d*.

43. The method of Art. 14 may be used in such examples as the following:

Example. How much will be left out of £17 9*s*. 6*d*., after paying bills of £2 14*s*. 4½*d*., £7 1*s*. 9½*d*., and £4 11*s*. 6½*d*.?

£	*s*.	*d*.
17	9	6
2	14	4½
7	1	9½
4	11	6½
£3	1	9½ *Ans*.

EXPLANATION. Write the £17 9*s*. 6*d*. first, and draw a line to separate it from the amounts written below.

Add up these latter, and make the sum up to £17 9*s*. 6*d*.

Thus, 2, 4, 6 far., and 2 far. = 2*d*., carry 2*d*.
2*d*., 8*d*., 17*d*., 21*d*., and 9*d*. = 2*s*. 6*d*., carry 2*s*.
2*s*., 3*s*., 4*s*., 8*s*., and 1*s*. = 9*s*.
10*s*., 20*s*. = £1, carry £1.
1, 5, 12, 14, and £3 = £17.

EXAMPLES 6

1. Subtract £219 17*s*. 4½*d*. from £432 4*s*. 2¼*d*.
2. What must be added to £1 19*s*. 7*d*., £4 1*s*. 3½*d*., £21 11*s*. 2¼*d*., £5 4*s*. 7¾*d*., to make the total amount to £54 9*s*. 6¾*d*.?
3. Subtract 15 cwt. 1 qr. 17 lbs. 5 oz. from 1 ton 2 qrs. 5 lbs. 4 oz.
4. Find the value of 11 guineas + 7 half-sovereigns + 3 crowns + 5 florins + 37 sixpences + 347 halfpence.
5. From 14 ac. 519 sq. yds. 7 sq. ft. take 9 ac. 1163 sq. yds. 8 sq. ft.
6. Add together 5 ac. 3 ro. 14 po. 18 yds., 16 ac. 1 ro. 28 po. 23 yds., 36 ac. 2 ro. 36 po. 19 yds., and 1 ac. 17 po.
7. Subtract 4 bush. 3 pks. 1 qt. from 7 bush. 1 gall. 1 pt.
8. Find the difference (in £ *s*. *d*.) between 79263 threepences and 65129 fourpences.

COMPOUND MULTIPLICATION

44. The sum of a given number of repetitions of a compound quantity is found by the method of [illegible] multiplication.

Example 1. Multiply £14 17*s*. 8½*d*. by 5.

£	*s*.	*d*.
14	17	8½
		5
£74	8	6½ *Ans*.

Say, 5 × 2 f. = 10 f. = 2½*d*., carry 2*d*.
5 × 8*d*. = 40*d*., and 2*d*. = 42*d*. = 3*s*. 6*d*., carry 3*s*.
5 × 7, 35, and 3, 38, put down 8, carry 3.
5 × 1, 5, and 3 = 8 (tens) = £4, carry 4.
5 × 4, 20, and 4 = 24.
5 × 1, 5, and 2 = 7.

45. If the multiplier has factors, each less than 13, and they are easily seen, proceed thus:

Example 2. Multiply £2 7*s*. 8¾*d*. by 54.

£	*s*.	*d*.
2	7	8¾
		9
21	9	6¾
		6
£128	17	4½ *Ans*

Here 9 × 6 = 54.
So first multiply by 9, as in Ex. 1 above, then multiply the product by 6.

Example 3. Multiply 4 cwt. 2 qrs. 8 lbs. by 33.

tons	cwt	qrs.	lbs
	4	2	8
			11
2	10	1	4
			3
7	10	3	12 *Ans*.

11 × 3 = 33.
Hence, 11 × 8 = 88 lbs. = 3 qrs. 4 lbs.
11 × 2 = 22, and 3, 25 qrs. = 6 cwt. 1 qr., etc.

46. If the multiplier cannot be expressed in factors less than 13, or if the factors are not readily found, the following method is used.

Example 4. Multiply £3 17*s*. 6½*d*. by 247.

£	*s*.	*d*.
3	17	6½
		10
38	15	5
		10
387	14	2
		2
775	8	4
155	1	8
27	2	9½
£957	12	9½ *Ans*.

EXPLANATION. We find 200 times the quantity, 40 times, and 7 times; then add the three results.
200 = 10 × 10 × 2; ∴ multiply by these factors, in order, giving £775 8*s*. 4*d*. Next, 40 = 10 × 4. We have already multiplied £3 17*s*. 6½*d*. by 10, so we have simply to multiply that result, viz. £38 15*s*. 5*d*. by 4, and write the product under the £775 8*s*. 4*d*. Finally, we multiply £3 17*s*. 6½*d*. by 7. The sum of these three products gives the required result.

COMPOUND DIVISION

47. In Art. 22 it was stated that division may be looked upon in either of two ways. When a quantity is to be divided into a number of equal parts, then,

(i.) if we know the number of parts, we can find the value of one part. This process is sometimes called *Partition*;

(ii.) if we know the value of one part, we can find the number of parts. This process is sometimes called *Quotition*.

The method of Partition will be understood from the following examples:

Example 1. Divide £16 11s. 5¼d. by 5.

```
  £   s.  d.
5 ) 16  11  5¼
   £3   6  3¼ Ans.
```

EXPLANATION. £16 divided by 5 gives £3 quotient, and £1 remainder. This £1 is 20s., which, with 11s. from the dividend, makes 31s. 31s. divided by 5 gives 6s. quotient, and 1s. remainder. Call this 12d., and 5d from the dividend, making 17d. Divide by 5, obtaining 3d. quotient, 2d. remainder. 2¼d. is 10 far., which, divided by 5, gives ½d.

Example 2. Divide £75 2s. 9¾d by 21.

```
      £   s  d
 3 ) 75   2  9¾
 7 ) 25   0 11   + 1 far.        )
      3  11  6¼  + 6 far × 3     ) 19 far.
   £3 11s 6¼d  + 19 far rem  Ans.
```

EXPLANATION 3 × 7 = 21.

After dividing by 3, there is 1 far. rem

Dividing this quotient by 7, we get £3 11s 6¼d and 6 far rem This means 6 far. from each of the 3 sums of £25 0s 11d Thus, the complete rem is 3 × 6 + 1 = 19 far.

Example 3 Divide £20748 19s. by 456.

```
         £    s  d.   £  s  d
456 ) 20748  19  0 ( 45 10  0½ Ans.
       2508
        228
         20
456 ) 4579 ( 10s
         19
         12
456 ) 228 ( 0d
          4
456 ) 912 ( 2f.
```

EXPLANATION. We divide £20748 by 456 exactly as in simple division (Art. 26).

There is a remainder of £228

Multiply the rem. by 20, and add in 19s. from the dividend. This gives 4579s.

Divide by 456, which gives 10s quotient and 19s. rem., i.e. 228d. 456 will not divide this, so we get 0d quotient.

Reduce the 228d to far. Then 912 far. divided by 456 gives 2f. quotient.

48. In Quotition, or the division of one quantity by another of the same kind, we first reduce the quantities to the same unit, and then proceed as in simple division

Example 1. £120 4s. 5½d is divided equally amongst a certain number of persons. If each of them gets £5 4s. 6½d. how many persons are there?

```
 £  s.  d.      £   s.  d.
 5  4   6½     120  4   5½
20              20
104s.          2404s.
 12              12
1254d.         28853d.
  2               2
2509 halfp.   57707 halfp.

2509 ) 57707 ( 23 persons Ans.
        7527
```

Here, we reduce each amount to halfpence.

The quotient of 57707 by 2509 is 23. ∴ there are 23 persons.

Example 2. How many times can 1 ton 4 cwt 22 lbs. be subtracted from 6 tons 12 cwt. 1 qr 18 lbs.? How many cwts., etc. will remain?

```
ton  cwt.  lbs.      tons  cwt.  qr.  lbs.
 1    4     22         6    12    1    18
20                    20
24 cwt.              132 cwt.
112                    4
470                  529 qrs.
224                   28
2710 lbs.            4250
                    1058
                    14830 lbs.

      2710 ) 14830 ( 5 times
   28 ( 4 )  1280 lbs. rem.
      ( 7 )   320
       4 )     45  qrs. 20 lbs.
               11  cwt. 1 qr. 20 lbs.
```

Here, reduce each to lbs. After the division we find 5 for quotient and 1280 lbs. remainder. This remainder is reduced to cwts. by method of Art. 39.

Thus the complete answer is that the subtraction can be done 5 times, and 11 cwt. 1 qr. 20 lbs. remains.

EXAMPLES 7

1. Multiply 5 mls. 6 fur. 54 yds. by 48.
2. Divide 184 tons 14 cwts. 3 qrs. 16 lbs. 13 oz. by 37.
3. Multiply £53 18s. 9½d. by 3042.
4. Divide £1946 13s. 11d. by 121, using factors.
5. Divide £1057 19s. 8d. by £3 9s. 7¼d.
6. How many halfcrowns will remain after £2 14s. 7d. is subtracted as often as possible from £87 19s. 2d.?
7. Divide £53 15s. 10d. among 10 men, giving 3 of them 10s. each more than the others. [Note: Subtract the extra 30s. from £53 15s. 10d. and divide the remainder equally among the ten men.]
8. Divide £11 9s. 6d. among 7 men, giving 2 of them twice as much each as the others get each.
9. A bat and ball together cost one guinea. If the bat cost 5 times as much as the ball, find the cost of each.
10. A woman bought 12 dozen eggs. If they had cost 3d. a dozen less, she could have bought 2 dozen more for the same money. What was the original price per dozen?
11. Coffee is bought at £6 10s. per cwt. and sold at 1s. 7d. per lb. How much is gained on 1 cwt.?
12. A packet containing 5 cigarettes and a coupon is sold for a penny; another packet is given for 5 coupons. How many cigarettes should be sold for a shilling?
13. Divide £29 15s. into an equal number of sovereigns, half-sovereigns, crowns, half-crowns, shillings, and sixpences.

CORRECTION. In last line but one of division 2, page 89, read number for *figures.*

CHARACTERISTICS OF IRON & STEEL

Iron in its modifications as Wrought Iron, Steel, and Cast Iron. A Short Introduction to the Fuller Course on Iron and Steel.

By Professor HENRY ADAMS

IRON [*Ferrum*; Symbol Fe, atomic weight 56] is a widely diffused metal known under three principal modifications as wrought iron, steel, and cast iron, each having very different properties primarily depending upon the amount of carbon (symbol C, atomic weight 12) entering into its composition. Briefly, wrought iron with very little carbon is fibrous, tough, soft, and ductile; may be forged, hammered, or rolled to various shapes. Steel, with more carbon, varies from fibrous to crystalline. When containing a small amount of carbon, it may be welded, and with more carbon may be cast. It can be forged and tempered, and is very tough and strong. Cast iron, containing the most carbon, is crystalline and brittle, fluid at high temperatures, and takes complicated shapes by casting in a mould.

Figure 28 gives a pictorial representation of the effect of carbon in iron. The block shown may be supposed to be formed of an infinite number of layers, the lowest being pure iron and the highest iron with as much carbon as it will hold. The black wedge shows the amount of carbon in the various layers if it could all be collected at one end.

Distinguishing Features. Workmen often require to distinguish these different modifications. Generally the shape and external appearance are sufficient to indicate the material, but there are precise tests. For instance, if made red hot, cast iron or malleable cast iron will fly to pieces when hammered. If plunged into water when red hot, steel will harden, while wrought iron will remain soft. They can also be distinguished very readily by the appearance of a fractured surface: wrought iron has a dull bluish fibrous fracture, with sometimes a small crystalline portion; mild steel has a silky appearance; while cast iron has a fine granular fracture generally on a dull grey colour. Cast steel has rather a more silvery fracture than cast iron, with very fine grain when of the best quality, as in tool steel. It is perhaps more difficult to distinguish between wrought iron and mild steel, particularly in work finished bright, but a drop of nitric acid will not produce any change upon wrought iron, while upon steel the colour of the spot will vary from brown to black according to the amount of carbon present, the reason being that the iron dissolves and leaves the carbon as a black deposit.

The following table by Bauerman shows very concisely the effect of carbon in iron:

Name.	Percentage of Carbon.	Properties.
Malleable iron	0·25	Is not sensibly hardened by sudden cooling.
Steely iron	0·35	Can be slightly hardened by quenching.
Steel	0·50	Gives sparks with a flint when hardened.
"	1·00 to 1·50	Limits for steel of maximum hardness and tenacity.
"	1·75	Superior limit of welding steel.
"	1·80	Very hard cast steel, forging with great difficulty.
"	1·90	Not malleable hot
Cast iron	2·00	Lower limits of cast iron, cannot be hammered
" "	6·00	Highest carburetted compound obtainable

Iron Ore. Iron is obtained by smelting various ores which are more or less rich in the metal. These ores may be classified as follows:

Oxides.—Magnetic Oxide, or Magnetite—from Sweden, Norway, North America, etc.

Red Hæmatite, or *Kidney Ore*—from Whitehaven and Ulverston. *Specular Iron Ore* is of the same composition, but of crystallised masses, and is found in Russia, Spain, Elba, etc.

Brown Hæmatite—differs from Red Hæmatite in containing water, and it is found at Forest of Dean, Alston Moor, Northamptonshire.

Carbonates.—Spathose Iron Ore, Spathic Ore, or Iron Glance—from Northumberland and Durham.

Argillaceous—Clay Ironstone or Clay Band—from South Wales, Dudley, North Staffordshire, Yorkshire, etc. Black Band Ironstone—from Ayrshire and Lanark, containing coaly impurities.

The Blast Furnace. Fortunately the coal measures occur close to the beds of ore, so that the fuel is on the spot and the cost of carriage is minimum. The hæmatite ores are nearly pure oxides, and they may be put direct into the blast furnace for producing the molten metal, but the other ores have to undergo a preliminary process of roasting. This consists of breaking the ore into pieces of convenient size, mixing it with coal in large heaps and allowing them to burn slowly so as to drive off the contained water, carbonic acid gas and sulphur. Or the ores may be roasted in a common kiln something like a lime kiln, or in a special form known as Gjers roasting kiln. The operation is known as calcining or roasting. The subsequent operation is as follows: the roasted ore, with earthy matter to form a flux, and fresh fuel to maintain heat, are smelted together in a blast furnace [29] from 50 to 100 feet high, to obtain the metal from the ore.

The blast furnaces are frequently in pairs, with a hoist between each pair for lifting the ore and fuel. The charge depends upon the par-

ticular kind of ore, but consists of, say, 5 cwt. of ore, 2 cwt. of limestone, and 5 cwt. of coke, repeated every half hour, the furnace being kept full.

In connection with the blast furnace is a large bed of moulding sand called a pig-bed, in which impressions are made by ramming the sand round wooden blocks three, four, or six feet long. Several rows of these impressions are made, and are connected by channels for conveying the molten metal from the blast furnace as in 30. The molten metal is run off every twelve hours, and when cool is broken up, the channels forming what are called *sows* and the separate impressions *pigs*.

The chemical action of the blast furnace is as follows: the silica, alumina, and iron in the ore and flux combine, by the aid of heat, to form a glassy slag, which floats on the molten metal and runs off near the bottom of the furnace, but at a higher point than the molten metal, which, being heavier, flows from the bottom. A small portion of the carbon in the fuel combines with the iron and keeps it fluid until it is drawn off at the tap hole. The remainder of the carbon of the fuel combines with the oxygen in the ore and the blast to form carbonic oxide or carbon monoxide (CO), carbonic acid or carbon dioxide (CO_2), etc., which pass out at the top, or are conveyed away to be used for raising steam by combustion under steam boilers. The reactions are shown in 31. Carbonic oxide is the gas dreaded in fiery mines and known as fire-damp. It causes explosions, burning with a blue flame. Carbonic acid is the fatal gas known as choke-damp, which is produced by the combustion of carbonic oxide and is the result of the explosions.

Classes of Pig Iron. Pig iron is classified under three main heads: *Bessemer iron*, *Foundry iron*, and *Forge iron*. Bessemer iron is made from hæmatite ores and used for conversion into steel on account of its freedom from impurities. Foundry iron is the name given to all pig iron having a grey fracture and large proportion of combined carbon; it is produced under a high temperature and full supply of fuel. This again is subdivided into three or six classes according to the ratio between the carbon chemically combined and that mechanically mixed.

Forge iron consists of white pig iron, almost free from uncombined carbon and suitable for conversion into wrought iron. It is produced with a low temperature or insufficient supply of fuel, and is frequently run from the blast furnace into iron moulds, rendering it brittle for ease in breaking up.

The foundry iron goes direct to the foundry, where the different qualities are mixed in various proportions according to the nature of the casting for which the metal is required.

The forge iron has to undergo other processes before the finished wrought iron is produced. The first process is refining, which is both a chemical and mechanical operation. This consists of melting the pig iron with coke or charcoal in an open hearth or refinery furnace [32] supplied with an air blast so as to impinge on the melted metal and furnish an oxidising atmosphere. This carries off a portion of the carbon, and at the same time removes a portion of the impurities in the form of slag. The melted metal is then poured into a cast iron trough lined with loam, kept cold by water circulating below, and the sudden chilling has the effect of causing the whole of the carbon to remain in chemical combination producing a hard silvery-white fracture. By this change the fluidity of the iron is reduced and the subsequent puddling process is facilitated. For common wrought iron the forge pig may go direct to the puddling furnace without undergoing the intermediate refining.

Puddling. There are two methods of puddling, called respectively dry puddling and wet puddling. Dry puddling is the process of obtaining wrought iron by burning the carbon out of refined cast iron in a reverberatory furnace [32]. The oxygen of the air, at the high temperature employed, combines with the carbon to form carbonic oxide gas which escapes, and with the silicon and other impurities which run off as slag. In hand-puddling the mass is stirred about until it is of sufficient tenacity to be lifted out of the furnace in balls or blooms of 60 to 80 lbs. each; a 5 cwt. charge takes about two hours to work off.

In Danks' rotary furnace the revolution of the furnace effects the same as hand labour. If the operation be stopped before the carbon is all removed, puddled steel is obtained. Wet puddling, or "pig-boiling," is the more modern process, in which grey unrefined pig-iron is converted direct. The bed of the reverberatory furnace is lined with broken slag, cinder, scale, etc., fused together, and over these a fettling of soft red hæmatite or *puddlers' mine* is placed.

The stages of the puddling process are—

(1) Graphitic carbon converted into combined carbon, and silicon partly oxidised by roasting and melting.

(2) Metal drawn from the sides, and mixed with that in the centre.

(3) Metal *boiled* for twenty minutes, impurities being oxidised by agitation of the mass.

(4) Pasty metal *balled* and re-balled ready for shingling.

After removal from the puddling furnace, at a welding heat, the blooms are put under a heavy trip hammer, a rotary squeezer, or a hydraulic press, to remove the slag and impurities from the spongy mass, and to solidify the metal. They are then passed through chilled rolls, flat or grooved, of various dimensions, to produce the shape required, being drawn down gradually to the finished size. After passing the bloom through the first series of rolls, it is known as puddled bar. These puddled bars are then cropped, piled, re-heated, welded, and rolled to form merchant bar. The material being again put through these processes becomes single, double, or treble best according to the number of repetitions. Cold rolling improves the tenacity and raises the limit of elasticity of wrought iron in a remarkable degree, but the ductility is somewhat diminished. It leaves the iron with a

34. Bessemer converter

35. Butt weld

36. Scarf weld

37. Vee weld

smooth, bright surface, free from the scale of black oxide which is left by hot rolling, and as it can be rolled exactly to gauge, there are many purposes for which it requires no further preparation.

Defects. There are two chief defects to which wrought iron is liable—cold-shortness and red-shortness. Cold-shortness is produced by the presence of phosphorus as an impurity; the iron is brittle when cold, but of ordinary character when heated; it cracks if bent cold but may be forged and welded at high temperatures. Red shortness is generally produced by the presence of sulphur, sometimes by arsenic, copper, and other impurities; the iron is tough when cold, but cannot be welded, and is difficult to forge at high temperatures.

Some parts of machinery require a hard wearing surface and a tough interior; the iron is then *case-hardened*. The piece is generally finished bright and then heated to a cherry red and placed in contact with broken prussiate of potash (K_4FeCy_6), scraps of leather, or other nitrogenous substances. The surface is thus converted into steel by the absorption of carbon and is hardened by quenching in water.

Steels. Steel may be made by the addition of carbon to wrought iron or the abstraction of carbon from cast iron; both methods are in use commercially, but the old classification by which the percentage of carbon alone determined the designation is now discarded, as some steel may have only the same amount of carbon as some wrought iron. It is the mode of manufacture which really determines the classification.

Blister steel is produced by a process called cementation. Bars of purest wrought iron are placed in a furnace between layers of charcoal powder, and kept at a high temperature (say, 1400° F.) for from five to fourteen days; the bars are now brittle, crystalline and more or less covered with blisters. This material is used for facing hammers, etc., but not for edge tools, and is largely used for conversion into other kinds of steel. *Spring steel* is blister steel heated to an orange red colour and rolled or hammered. *Shear steel* is blister steel cut into short lengths, piled into faggots, sprinkled with sand and borax to form a flux, and placed at welding heat under a tilt hammer. Single and double shear steel denotes the number of times the process is repeated. It is used for large knives, scythes, plane irons, shears, etc., frequently in conjunction with iron.

Bessemer steel is made from grey pig iron containing a large proportion of free carbon, a small quantity of silicon and manganese, but free from sulphur and phosphorus. The iron is melted in a cupola [33], somewhat similar to a small blast furnace, and run into a converter lined with fire-brick and suspended on hollow trunnions [34]. Air is blown through the metal for about twenty minutes to remove all the carbon; five to ten per cent. of spiegeleisen is then added, and blowing is resumed long enough to incorporate the two metals. The converter is then partly rotated and the molten metal poured out into a large ladle which is carried by a crane round a series of moulds into which the metal is poured to form ingots. The ingots, when cold, being porous, are reheated and put under a steam hammer, then rolled or worked as required.

Bessemer steel is used for rails, tyres, rolled joists, common cutlery and tools, roofs, bridges, etc. *Gilchrist-Thomas*, or *basic* steel, is similar to Bessemer, but there is a difference in the lining of the converter, which is basic, or non-siliceous, made from burnt dolomite or magnesian limestone. By this process the phosphorus is quickly and cheaply eliminated by combining with the lime, and inferior iron may consequently be employed.

Siemens' Steels. A very ductile steel is produced by the various open-hearth Siemens' processes, the principal of which is perhaps the Landore Siemens steel. The iron ore is treated in a rotary furnace with carbonaceous material and converted into balls of malleable iron, which are transferred direct to the steel melting furnace, where spiegeleisen is added. The result is steel of a very ductile quality, dense and uniform in texture, and by a careful proportioning of the materials any required degree of toughness and hardness may be obtained. Structural steel may be divided into three grades: *mild* or *soft* below 0·15 per cent. of carbon content and suitable for boiler plates and similar uses; *medium*, 0·15 to 0·30 per cent. of carbon, for joists and general structural purposes; *hard*, above 0·30 per cent. of carbon, for axles and shafts, etc., where wearing surfaces are desired.

Compressed steel is made by the application of pressure to the fluid metal, and the resulting steel is of superior density and tenacity, besides being free from blow holes.

Crucible Cast Steel. Crucible cast steel was originally made by melting fragments of blister steel in covered fireclay crucibles and running into iron moulds. It is now generally made direct from Swedish bars cut up and placed in crucibles with a small quantity of charcoal and the subsequent addition of spiegeleisen, or oxide of manganese. It may be forged at a low cherry red, but is unweldable; the fracture is grey and the crystals very minute. It is used for tool steel, and there are many varieties produced by slight differences in the ingredients, such as Heath's and Mushet's steels, Tungsten steel, Chrome steel, Harveyised steel, Nickel steel, and various high speed tool steels.

Dannemora cast steel may be taken as typical, the properties according to the amount of carbon being shown in the following table:

Carbon	Temper.	Tools suitable for.	Remarks.
$1\frac{1}{2}$	Razor	Turning, planing, drills, etc.	Great skill required in forging. Overheating will spoil.
$1\frac{1}{4}$	Turning Tool	Turning, planing and slotting tools, drills, small cutters and taps.	Not weldable.

No.	Temper.	Tools suitable for.	Remarks.
[illegible]	Punch	Mill picks, circular cutters, taps, rimers, small shear-blades, large turning tools and drills, punches and screwing dies.	May be welded with great care.
[illegible]	Chisel	Cold chisels, hot setts, medium size shear-blades, large punches, large taps, miners' drills for granite	Will weld with care
[illegible]	Sett	Cold setts, minting dies, large shear-blades, miners' drills; smiths' tools, as sett hammers, swages, flatteners, fullers, etc.	Will weld without difficulty.
[illegible]	Die	Boiler cups, snaps, hammers, stamping and pressing dies, welding steel for plane-irons, etc.	Will weld like iron

New varieties of steel besides those named are introduced from time to time, particularly for use in the construction of armour plates, but the reputation with which they start is not always maintained.

Cast Irons. Reverting to cast iron for foundry use, there are three usual divisions.

No. 1. *Grey.* This is soft and deficient in strength, very fluid when melted and used for ordinary castings; it contains from 0·6 to 1·5 per cent. of carbon chemically combined, and 2·9 to 3·7 per cent. mechanically combined.

No. 2. *Mottled.* This is of variable hardness and takes its name from its appearance; it is stronger than No. 1, and is used for larger castings; it has more carbon chemically combined and less mechanically.

No. 3. *White.* This is very hard, strong, and fusible, containing three to five per cent. of carbon all chemically combined. It is of more use for conversion into wrought iron than for foundry purposes; but all three varieties may be mixed in various proportions for different purposes. Grey cast iron gets stronger when remelted, partly by the burning out of some of the carbon and partly by the greater proportion which becomes chemically combined. Castings that have to be machined are more easily worked when of grey metal, but a certain proportion of No. 2 has generally to be introduced to secure the requisite strength.

Chilled Cast Iron. For certain purposes a very hard face is required, as on the tread of cast iron wheels, rolls for rolling mills, and points of Palliser shells, etc. This is obtained by running the metal into a mould of white or hard cast iron for the part requiring to be chilled, protected by a wash of loam, when the sudden cooling causes a chemical combination of the molten iron and carbon. The fracture is always silvery and the direction of the crystallisation strongly marked.

Malleable Cast Iron. Malleable cast iron is made by heating ordinary castings, preferably of white cast iron, from two to forty hours according to size, in contact with oxide of iron or powdered red hæmatite, which causes a partial conversion into wrought iron by the abstraction of carbon, and a consequent change from the brittleness of a casting to the toughness of common wrought iron; it is used for cheap spanners and work of that kind. Malleable cast iron is rather a misnomer, as the material can neither be forged nor welded.

Another mode of toughening cast iron is to melt with it from one-fourth to one-seventh of its weight of wrought iron scrap; some of the carbon in the cast iron unites with the wrought iron, and the mixture, having a smaller percentage of carbon as a whole, forms an approximation to steel. Although wrought iron in the ordinary way cannot be melted, but only becomes a pasty mass when heated, the addition of a minute quantity of aluminium, by Nordenfelt's *Mitis* process, enables it to melt and flow sufficiently to form castings having all the properties of wrought iron, except that they are perfectly homogeneous and free from stratification; Mitis metal will both weld and harden.

Metallography or Micro-metallurgy. The use of the microscope in connection with the structure of a chilled casting was first mentioned by Réaumur in 1722. In 1833 François followed with the microscope the successive steps in the reduction of iron from its ores. In 1864 Dr. Sorby, studying polished and etched specimens of iron and steel, said "steel must be regarded as an artificial crystallised rock, and to get a complete knowledge of it, must be regarded as such." About 1870 the writer recommended a study of the crystallisation of metals to an inquirer for subjects for original microscopical research in the *English Mechanic*, but the subject was not taken up practically until about 25 years later, when several investigators entered the field. From 1885 onwards many workers have been investigating the same subject, extending their labours to the micro structure of various alloys.

Forging, welding, and tempering are so intimately connected with wrought iron and steel that a brief description of these processes will be of some interest.

Forging. Wrought iron at a red heat may be hammered into various shapes called *forging*. When a piece is drawn down smaller, the process is called *swaging*, and when *jumped up* or hammered on the end to increase the thickness it is called *upsetting*. The more working the iron has undergone the more suitable it is for forging; common iron is not suitable, as the scale or slag in it causes it to crack. When the forging does not involve much alteration of shape, double-best may be used, but where flanging is required, as in boiler work, it is necessary to use treble-best.

Yorkshire iron is more ductile and malleable than any other, and is therefore used for important flanging or difficult forgings. For light and complicated work, such as boat hooks, charcoal iron is used. Mild steel may be forged, but it is necessary to proceed by easy stages, and it is of the utmost importance not to continue the work when the steel has reached a blue heat, or it will require annealing to remove the internal stresses that are caused.

Stamping between Dies is a modern method for making articles in wrought iron and mild steel, under the steam hammer (called drop forging) or in a hydraulic press (called pressing). The material is brought to forging heat and pressed in a single pair of dies or a graduated series, according to the amount of working it has to undergo. Spanners, draw-bar hooks, crane-hooks, steel chain, pans and dishes, elevator buckets, wheel barrow trays, and numberless articles of all kinds are thus manufactured.

Welding. Welding is the process of joining two pieces of wrought iron or steel by heating and hammering them together. To weld iron the pieces must be brought to a white heat, just scintillating, and the scale of black oxide must be swept off before they are put together. Steel requires a much lower heat, and the surfaces should be sprinkled with sand, borax, or silicate of soda, to protect them from oxidation and to aid the surface fusion. The welding temperature of steel depends upon the amount of carbon contained: hence the extra difficulty of welding two pieces of different composition. The average loss of strength in a weld is from 15 to 20 per cent., but the weld is often assisted by scarfing the two pieces together. There are three forms of welding applicable to a bar, the butt weld [35], the scarf weld [36], and the lock, vee, or grip weld [37]. The ends are first upset so as to allow of sufficient reduction in the hammering to make the weld solid without reducing the diameter below the normal size, then shaped as shown, brought to welding heat, and completed by hammering between hollow swages.

One form of welding consists in passing an electric current through the pieces to be joined. The ends are rounded so that they touch in the centre first, and the small area of contact offers great resistance to the passage of the current, which is thereby transformed into heat and surface fusion commences immediately. As the junction commences in the centre and proceeds uniformly to the outside, it is very efficient, and the weld is said to be of equal strength with the solid material, but unless great care is taken there may be a loss of 5 to 10 per cent.

Thermit welding is another form. Thermit is a mixture of aluminium and oxide of iron in fine grain and in chemical proportion. It can be ignited by a powder formed of finely divided peroxide of barium and aluminium, which may be lighted by a match. The thermit when fused has a temperature of about 5000 degrees Fahrenheit, and a little poured upon rail ends to be welded, confined in a suitable mould or case, quickly raises them to welding heat and pressure completes the joint.

Face Welding, equivalent to veneering, may also be accomplished by the hot rolling of clean metal ingots, of similar or different kinds, having a thin sheet of aluminium interposed. Thus a compound sheet of iron and copper may be produced in this way with any relative thickness of the two external metals.

Tempering. When steel is heated to a cherry red and suddenly cooled in water or oil it is rendered very hard. The exact change produced is not known, but it is supposed by some that the carbon is caused to take the crystalline or diamond form. This is the first part of the operation. If it is a tool that is being tempered, the end only is dipped in water and then brightened with a piece of grindstone, and watched until the heat travels down from the unquenched portion and causes a film of oxide to show on the brightened surface. When this reaches the desired colour the tool is plunged into water, and the hardness is found to be *let down* to the *temper* required. The following table of the colours corresponding to temperature will be found useful.

	Degrees Fahrenheit.
Lowest red heat visible in the dark ..	635
Faint red	960
Dull red	1290
Brilliant red	1470
Cherry red	1650
Bright cherry red	1830
Orange	2010
Bright orange	2190
White heat	2370
Bright white heat	2550
Dazzling white heat	2730
Welding or scintillating heat	2800

The colours at which the various tools are tempered will be found in the following table:

Colour of Film.	Temp. Fahr	Nature of Tool.
Very pale yellow straw	430	Lancets and turning tools for cast iron.
Shade of darker yellow	450	Razors and ditto.
Golden yellow	470	Penknives, turning-tools for iron.
Orange yellow	490	Cold chisels, drills, screw taps, wood tools.
Brownish yellow	500	Hatchets, plane-irons, chipping-chisels, saws for iron, tools for working granite, turning tools for brass.
Brown tinged with purple ...	520	
Light purple ...	530	Swords, ordinary springs, tools for cutting sandstone.
Full purple ...	550	
Full blue ...	570	Small saws, watch-springs, augurs.
Grey blue ...	600	Large saws, pit and hand saws.
Pale blue with tinge of green	630	Too soft for steel instruments.
Grey	750	

Tempering may be done in a bath of molten metal. Different proportions of lead and tin become fusible at temperatures varying from about 400 to 620 degrees Fahrenheit, and thus provide any requisite temperature between those limits. Watchmakers' drills and such small articles are sometimes tempered by making them red hot and thrusting them into a tallow candle. Some tool-makers have their own recipes, salt water, vinegar and water, urine, etc., being among the number.

HOW SCIENCE MAY TRANSFORM THE WORLD

The Remarkable Advance of Chemistry in Our Own Time and the Wonderful Secrets it may Hold for the Future

By Dr. SALEEBY

AT the present day chemistry is one of the most flourishing of all the sciences. Certainly none other, save medical science, can claim such a number of earnest students. Many large manufacturing firms in Germany think nothing of employing some *hundreds* of trained chemists in order to prosecute research in the interests of the house.

Hence it is that during recent years chemistry has made remarkable advances. It is not desirable here to anticipate the discussion of these, but it is the present purpose to indicate, as far as may be, the prospects of chemistry.

For convenience we may consider, first, the future of chemical practice, and then the future of chemical theory.

The Elements. Only a few years ago it might have been said that chemistry had no new elements to discover—save perhaps one or two elements in the stars or the sun, which were supposed to be unrepresented on the earth. But the prophecy would have been wrong, for the introduction of new methods has lately enabled Sir William Ramsay to discover not merely argon, but also some five or six new elementary gases, which occur in minute quantities in the atmosphere. Nevertheless, it is probable that only very few and very unimportant elements still remain undetected. The revelation of radium will probably prove to have been the last important discovery in this direction.

Nor is practical chemistry likely to witness any striking discoveries in new compounds in what is called *inorganic chemistry*, the chemistry which mainly deals with compounds that contain no carbon. Lately Dr. Marshall, of Edinburgh, has discovered the compounds known as the persulphates, but these are of small importance, and there are probably not many more to follow.

Synthesis. But the future of practical chemistry will be mainly concerned with the artificial production of complex compounds, containing carbon. Large treatises have already been written that are concerned solely with the artificial manufacture by *synthesis* (putting together) of products which have hitherto been obtainable only through the agency of the living animal or plant. This *chemical synthesis of vital products* will occupy a very important place in the chemistry of the future. Already the chemist can build up from the elements such complex substances as camphor, vanilla, alcohol, some sugars, and even the simplest forms of what is called albumin—best represented by white of egg. Even when these "vital products" cannot be built up from their elements, they may be obtained from coal tar. The chemistry of coal-tar will play a large part in the future of chemical science.

If we were to express the difference between the past and the future of chemistry in the shortest form, it would be said that past chemistry has been almost exclusively *analytic*—analysis being the process of breaking anything down into its constituent elements—and that, this process having now been carried practically to its natural limits, present and future chemistry are concerned with the opposite process of *synthesis*. Analytical chemistry is almost a perfect science; synthetic chemistry—the father of which, M. Berthelot, is alive to-day—is still in its infancy.

The Field of Synthetic Chemistry. But we must not imagine that synthetic chemistry is or will be concerned merely with the artificial building up of compounds already known to be produced by the living animal or vegetable organism. On the contrary, synthetic chemistry has already produced, and is daily producing, an illimitable series of new compounds which are absolutely unknown in Nature. The manufacture of these compounds is of some interest to the theorist, of course, for the theorist can afford to ignore no fact; but it is chiefly pursued for practical ends. Of these the least important is the service of the dyeing industry by the production of dyes superior to any that can be obtained from the vegetable world. But the most important end, and that which individually, perhaps, occupies the majority of these investigators, is the service of medicine.

Indeed, contemporary chemistry goes far to vindicate the teaching of Paracelsus, that "The true use of chemistry is not to make gold, but to prepare medicines." Not so long ago the study of *Materia Medica*, or "medical materials" (to translate very loosely), was practically a department of applied botany. But anyone who cares to compare the text-books on this subject written a generation ago with those now being published, will find that a most astonishing change has come over the treatment. The vegetable world is being slowly excluded from such text-books, and it is hard to say where the process will end. Perhaps the majority of the drugs on which the modern physician now relies were unheard of thirty years ago. Indeed, they did not exist. They have, most of them, been manufactured, for the first time in the history of things, in German laboratories. Amongst them are included drugs which are now in universal use, and invaluable to the physician. After chloroform and carbolic acid come a host of drugs which relieve pain, stimulate various

organs, procure sleep, and so forth. But physicians have not yet obtained the ideal anæsthetic, or the ideal hypnotic, or the ideal antiseptic. With these, and with many more, the chemistry of the future will be able to supply them.

The Solver of World Problems. Again, the chemistry of the future will be of incalculable importance in solving some of the most difficult problems that confront humanity. Of these there are not a few that might be named. At present, for instance, mankind is living on its capital of coal: it is to chemistry that we must turn for a new fuel when the coalfields are exhausted. But by far the most important problem which the chemistry of the future will have to solve—and doubtless will solve—is the problem known as the "fixation of the atmospheric nitrogen." The reader is already aware of the abundance of nitrogen in the atmosphere. Now this element is an essential part of the food of man and of the food of the plant—upon which, in the last resort, man lives. But plants cannot absorb nitrogen directly from the air any more than we can, though four-fifths of every breath we draw consists of this gas. The wheat plant and man cannot *fix* the atmospheric nitrogen. Man cannot even utilise nitrogen when it is presented to him in the form of its simple compounds. He can utilise it only when it has been "worked up" by the plant into those exceedingly complex compounds which we call the albumins or proteids. Now the plant *can* utilise the nitrogen which is presented to it in the simple compounds, later to be studied, which are called nitrates. The only exceptions to the rule that a plant can take in its nitrogen only as nitrates are furnished by a few plants of the order called Leguminosæ, whose roots are lived upon by certain "nitrifying bacteria," which can take in the free nitrogen of the "soil air" and hand it on to the plant. Hence the constant supply of nitrates is necessary for the growth of the corn of the world; and at present we are rapidly using up the store of nitrates, which mainly occur in South America. When there is no more nitrate to be obtained we shall be in a sorry plight. But it may quite reasonably be expected that, ere then, chemistry will have learnt how to fix the atmospheric nitrogen easily, cheaply, and in the enormous quantities that will be required. Already the fixation can be accomplished by the use of electricity, but only in very small quantities and at a prohibitive cost.

In the World's Food Supply. Many other problems connected with the future food supply of the world's population—which is increasing in numbers at an enormous rate—will be solved by the chemistry of the future. Doubtless we shall learn, for instance, to manufacture sugar quite cheaply, and thus to procure an unlimited supply of one of the most valuable of all foodstuffs.

Lastly, a word may be said as to the future of chemical theory; but the subject need not detain us long, since it will be referred to in the chapter on physical chemistry. But we may note that the theoretical advance of the last few years makes it more than probable that the chemists of the future will be able to manufacture the so-called elements themselves at will. The conventional values at present attached to gold and silver will have to be readjusted. These precious metals will be manufactured only for their beauty and durability in the arts. But other metals, even more valuable, and far more useful, will be manufactured—metals such as platinum, and others, which have special properties that render them of use.

Relation of Chemistry to Electricity. Further, theoretical chemistry will become completely allied and unified with those branches of physics which we call electricity and magnetism. Already the old terms, such as *chemical attraction* and *chemical affinity*, are beginning to be ruled out of date, for we are learning that these *affinities* really depend not, as the old Greek thinker thought, upon the "loves and hates of the atoms," but upon the electrical properties of the different elements.

It is, indeed, not too much to say that the whole theory of chemistry will be resolved into a mere subdivision of the theory of electricity. This prospective advance has been already initiated by the study of radium and radioactivity. Indeed, it seems hardly too much to say that chemical theory will ere long reach a complete and final stage. The laws discovered by the students of the past hundred years will take their place beside and among the laws which the physicist has discovered. Let us remember our definition of the province of chemistry, and we shall see that the science which deals with the consequences of the fact that matter is of different kinds must plainly be resolved, at last, into the science which treats of matter of whatever kind. This is another way of saying that the *chemical forces* of which we now find it convenient to speak are not special and peculiar, but are none other than particular manifestations of the *physical forces* which act everywhere. The forces of *valency* and *affinity* and so forth, which we must study later, are already being regarded as merely particular expressions of that omnipresent force which we call electricity.

But though chemical theory will in all probability have become perfected in another century, no limit can be set to the possibilities of practical chemistry. The number of possible compounds which may be manufactured in the laboratories of the future is almost infinite. Nor can their utility to mankind be measured.

The Relations of the Elements. We cannot look at the periodic law without coming to the necessary conclusion that the elements are related; and we cannot philosophically come to this conclusion without being led to the further conclusion that their relationship implies common origin and an ultimate identity of nature. We have already seen that it is necessary to reject the simple hypothesis that the atoms of all the other elements are

compounded of atoms of hydrogen, and we come upon this final parting of the ways: either the periodic law means nothing, the relationship of the elements is only apparent, a mere matter of chance—or the atoms are not atoms. As everyone knows, it is to this last conclusion that Chemistry has been forced.

Atoms, Animals, and Plants. Professor George Darwin's Presidential Address to the Meeting of the British Association in South Africa in August of this year (1905) has clearly put before every reader the amazing analogy between the atoms of the elements and the individuals of any species of animal or plant. The elements are species, their atoms correspond to the individuals of species, and they are subject to change, to variation, to origin, and to disappearance, just like any living species, and in virtue of the same underlying causes and principles of evolution, of which the chief is natural selection—which chooses the individual organism or the individual atom that is the fittest to survive in the environment or the surroundings in which it is placed. We must later consider this theory of atomic evolution; meanwhile we note its incompatibility with the theory that atoms are ultimates. We must regard atoms, on the contrary, as fleeting phases of matter, none of which are eternal, even though some of them may last for millions of years. Here, then, we leave the periodic law, which has been invaluable to us, and will proceed to consider in brief the main characters of the principal elements, their distribution, the principles of their preparation, and their more important compounds.

Elements in the Free State. Some of the Elements are found in nature as such, or, as we say, in the *free state;* but more usually they are found as compounds which have to be decomposed before we can obtain and free the element. Three very important elements constitute by far the greatest part of the entire crust of the earth. These are *Silicon, Aluminium* and *Oxygen*—the latter of which the earth's crust has doubtless imprisoned from the atmosphere.

The greater bulk of the earth's atmosphere is made up of Oxygen and Nitrogen, each being in the free or uncombined state. Three more elements much less abundant, *Phosphorus, Sulphur,* and *Carbon,* are found widely spread in rocks and minerals and in sea water, though their total amount is small compared with that of the elements already named. Of these, however, the last—Carbon—is in some ways of supreme importance, for when we turn to the kinds of matter in which life is displayed, we find that carbon is the most abundant element therein. Now Silicon is the most abundant element in the *inorganic* or *lifeless* world; and it is possible to draw certain interesting comparisons between the chemical properties of this element Silicon and the element Carbon. We note this resemblance because it is of use in aiding the memory of the student, but we do not dwell upon it, because we must regard it as casual and not as possessed of the deeper significance which at first sight is certainly suggested.

Rarer Elements. All the remaining elements are relatively less abundant; even iron constitutes only a small portion of the earth's crust, though we think of it as such a common element. Radium, again, is almost infinitely rare; but we are learning in the case of Radium and other very rare elements to explain their rarity in a way which would have astonished the older chemists. Nowadays we regard them as rare merely because their lives are so short; and thus they make but a poor show when we come to make comparative estimates of the amounts of the various elements at any given moment. Lead, for instance, is by no means an uncommon element; certainly no one thinks of it as rare; but there is reason to believe that lead is actually no other than a very prolonged and therefore conspicuous stage in the evolution of certain atoms, radium representing a very brief stage in the earlier part of that evolution. This may be very loosely but graphically expressed in the saying that lead is the last stage of Radium. So much for the relative abundance of the elements, but to this we may add a brief table from Sir William Ramsay, the world-famous Professor at University College, London, which gives us some idea of the relative amounts of the elements that occur at the surface of the earth, including land, sea, and sky—that is to say, the earth's crust, the waters of the oceans, and the atmosphere:

Oxygen	50·0	Titanium	0·30
Silicon	25·3	Carbon	0·20
Aluminium	7·3	Chlorine	0·15
Iron	5·1	Phosphorus	0·09
Calcium	3·5	Manganese	0·07
Magnesium	2·5	Sulphur	0·04
Sodium	2·3	Barium	0·03
Potassium	2·2	Nitrogen	0·02
Hydrogen	1·0	Chromium	0·01

The Metals. An ancient and familiar division of the elements is into *metals* and *non-metals.* Everyone knows what the obvious characters of a metal are. It usually has a characteristic appearance or metallic lustre; it is usually heavy, and has physical properties which make it of practical value. The metals are exceptionally good conductors of heat and of electricity. In all these characters they are contrasted with the non-metals. All the metals are solid at ordinary temperatures with one exception, *Mercury.* This division of the elements is not strictly scientific, and very little further reference will be made to it, but we may here consider the common characters which make it convenient to retain the old name, and the few words we have to say will form a suitable introduction to the course on METALLURGY.

There are now known more than fifty metals, of which six were familiar to the ancients and are mentioned in the Bible; these are Gold, Silver, Tin, Copper, Iron, and Lead. In time past it was attempted to frame rigid definitions of the metals, and the first definition, now more than 1000 years old, insisted on the properties of fusibility and malleability as the essential characters of metals. Fusibility is the quality of undergoing liquefaction without other change

when great heat is applied. Malleability is the property in virtue of which a substance can be beaten out with a hammer (Latin *malleus*).

The Alchemists. The Alchemists paid immense attention to the metals because gold is a metal, and it was naturally from the other metals that they expected to be able to manufacture gold—an idea by no means so remote from possibility as we used to think. The fact of solidity was also regarded as essential to a metal; thus mercury was not regarded as a metal until it had been frozen—that is to say, solidified by cold. When Antimony and similar substances were discovered, they were regarded as semi-metals because they were not malleable, but brittle when struck with a hammer. Antimony, bismuth, and some other elements we often still speak of as metalloids—the termination *oid* implying *likeness*; it almost corresponds to the English "ish," and the metalloids are not exactly metals but *metallish*. However, that distinction was shown to be of small value, and the definition of a metal came to rest upon the possession of metallic lustre and of great weight; but many of the non-metals have a metallic lustre, and amongst the metals is the element lithium, which is actually the lightest solid known. Hence it is now impossible to form a satisfactory definition of the metals.

A Working Definition of Metals. We have dealt with this subject at none too great length because there is much instruction for us in the history of the changes which increasing knowledge has brought in our chemical conceptions. One by one the characters supposed to be essential to metals have had to be given up, and finally we see that there is no rigid demarcation in nature that corresponds to our rigid conception. But we may frame a "working definition" of the metals which is quite useful. We may say that a metal is a substance which in the first place combines with oxygen to form what we call an oxide. The character of these compounds with oxygen is that, as a class, they have a particular affinity for the compounds of non-metals with oxygen. The compounds of metals with oxygen are called *bases*; the compounds of non-metals with oxygen are called *acids; and the union of a base with an acid results in the formation of a salt*. This is a good definition, for instances can be adduced to show that certain of the elements are capable of acting either as metals or as non-metals in accordance with it. Sometimes the union of such a metal or metalloid with oxygen has a basic character and sometimes an acid character. So much for the metals in general. [See METALLURGY.]

To be continued

HOW TO USE APPARATUS IN CHEMISTRY

Electrolytic Apparatus. Sometimes in the course of his experimental work the chemist has occasion to decompose a substance by means of electricity.

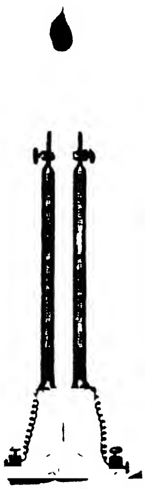
The instrument consists of three glass tubes united at one end. The two principal tubes form a U, and from the loop of the U the third tube springs parallel to the other two. The principal tubes terminate in little glass stop-cocks, while the third, or branch tube, tends in a bulb of sufficient capacity to hold the entire contents of all three tubes. The bulb is open at the top, and is about an inch above the stop-cocks. Two inches from the bend of the U a small piece of platinum foil is enclosed in each of the two principal tubes, and the foil is fastened to a platinum wire which is either fused into the wall of the tube passing through it, or passes through a small cork fitting into an opening in the slide of the tube.

In decomposing a fluid by means of electricity to electrolyse it, the fluid is poured into the bulb, the two stop-cocks being open, till the three tubes are full, though the bulb itself is empty. The stop-cocks of the principal tubes are then closed, and the wires from a powerful series of batteries are attached to the two little platinum plates. As the liquid is decomposed the gases arise in the principal tubes, and by their pressure drive the liquid up into the bulb.

Combustion Furnace. When resolving an organic compound into its elements to discover how much carbon, oxygen, hydrogen, and so forth there may be in it, we have to make use of a combustion furnace. There are a large number of furnaces in use, but they differ only in minor points of construction. Perhaps the most typical is that known as Erlenmeyer's furnace. This consists of twenty-four Bunsen burners, which lie beneath a fuel clay trough, on which the combustion tube lies. The combustion tube itself is simply a tube of very hard glass specially made for the purpose, and its exact form depends entirely upon the object of the analysis. It has either two straight ends, or one end is drawn out into a point and turned up. In either case it is laid on the fire-clay support, and cautiously attached to the auxiliary apparatus, which may be a gas holder for forcing air through it at one end, and a calcium chloride tube and potash bulbs at the other; or it may be an apparatus for collecting the nitrogen evolved. The order in which the different parts of the tube are heated also depends on the nature of the analysis, but the student will do well to be cautious in heating his tubes. If he is not careful he will cause them to bulge and possibly to crack. Again, by turning on the gas too suddenly he may crack the fire-clay support.

Heat Regulation. Besides requiring great heat, the chemist may find it necessary to keep an object at a fixed temperature. This is effected by means of gas regulators, working automatically. The principle of all these is this: An arrangement of glass tubes is made so that the gas has to pass over the face of some mercury on its passage to the burner. This mercury is in reality a thermometer, and as the temperature rises it tends to cut off the gas supply. Perhaps the best of these heat regulators is that made by Reichert, of Vienna, though quite efficient instruments can be made by the chemist himself.

To operate Reichert's regulator, the bulb of the thermometer tube is inserted in the oven, or flask, which should be maintained at a certain temperature. The auxiliary burner is placed beneath the object, being connected by tubing—preferably of metal, but often of india-rubber—to the regulator. A second thermometer is also inserted in the object. By means of an ordinary burner the temperature is raised to within a degree of the desired point. Then the common burner is removed, and the gas allowed to pass through the regulator, the pin-hole burner of which is lighted. After a few minutes the thermometer will reach the desired temperature, and the regulating screw must then be turned till the mercury is just touching the bottom of the inner tube. If, when that is done, the temperature of the oven or flask rises the slightest fraction above the indicated point, the mercury will cut off the gas and the pin-hole burner will keep the object just warm. At the same time, when the temperature falls below the selected point, the larger burner should be called into play and the heat at once increased. An hour's experimenting with one of these burners should enable the student to keep an oven at a fixed temperature day and night for weeks.

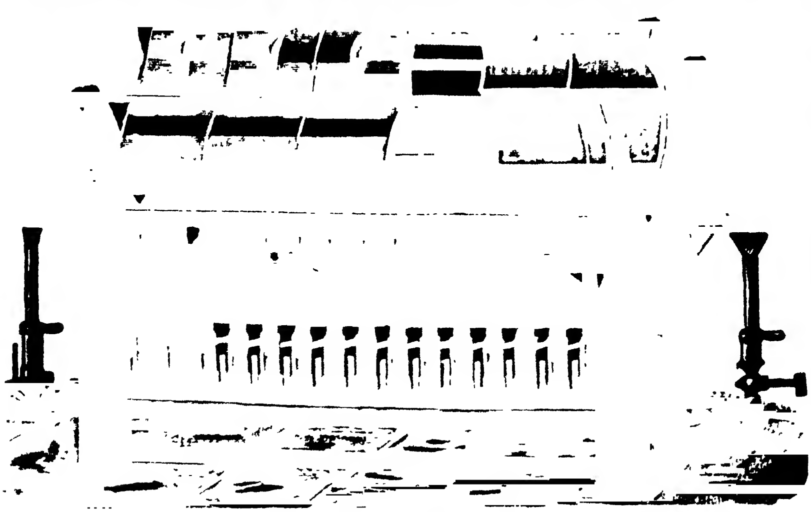


DECOMPOSING TUBE

Distillation. What is the importance of being thus able to regulate heat? It is important in many ways. In distillation much time and trouble is saved by this means. In many important operations of Organic Chemistry it is desirable to distil substances at varying temperatures. But first a word on the ordinary methods of distillation will be helpful.

The fluid to be distilled is placed in a retort which should be fitted with an extra tube through which a thermometer passes. The liquid should not fill more than a third of the retort. Overfilling these awkward vessels is responsible, perhaps, for more breakages than anything else. At the end of the retort is a condenser, through which a stream of water continually passes, and the condenser ends in the flask destined to receive the distillate. Note that the end of the retort must be fitted to the condenser with a cork or rubber tubing, but unless the distillate is very volatile there is no need in general practice for the condenser to be united to the receiver; in fact, in most cases it is preferable that it should be quite free in the neck of the flask. In simple distilling the liquid is heated to its boiling point, and there kept boiling briskly, while the vapour passes over the condenser and returns to the fluid state.

In fractional distillation the matter is different. It is generally preferable to use a flask fitted with a cork through which two holes are bored. Through one of these holes the thermometer of the heat regulator is passed, and through the other is passed a wide glass tube having a branch tube bent downwards, reaching out of its side. In the upper half of this tube we fit our standard thermometer, closing the top and taking care that when the desired temperature is reached the column of mercury in the thermometer shall just pass through the cork. The bent side-tube is attached to the condenser. Then the liquid in the flask is brought to the lowest of the temperatures at which we wish to distil, the gas regulator is adjusted, and the operation progresses automatically. When nothing more can be seen dripping into the receiver, allow five minutes to pass, put on a clean receiver, unscrew the regulator of the gas controller, raise the temperature to the next point, and repeat these operations till the temperature has been successfully dealt with. It is always advisable to allow five minutes' grace; many a promising distillation has been ruined by over haste.



COMBUSTION FURNACE

LATIN. ENGLISH. GERMAN

Latin and English, by G. K. HIBBERT, M.A., Classical Master at Broadgate School, Nottingham; German, by Dr. OSTEN, Dramatist, and P. G. KONODY

LATIN

By Gerald K. Hibbert, M.A.

Section I. GRAMMAR

Nouns: Fourth Declension: *-u* stems. [The Third Declension will be taken next lesson.] Nominative ends in *-us* (mostly masculine) and in *-u* (always neuter).

	Singular.	*Plural.*
N. V.	gradus, *a step*	gradūs
Acc.	gradum	(gradūs)
Gen.	gradūs	graduum
Dat.	gradui	gradibus
Abl.	gradu	(*or* gradubus)
N. V. A.	genu, *a knee*	genua
Gen.	genūs	genuum
Dat.	genu	genibus
Abl.	genu	(*or* genubus)

A few nouns of this declension ending in *-us* are feminine: *e.g.*, *manus* (hand), *acus* (needle), *domus* (house), *tribus* (tribe), *porticus* (porch), *anus* (old woman). *Domus* makes dat. sing. *domui* or *domo*, abl. *domo*, acc. pl. *-us* or *-os*, gen. *domuum* or *domorum* (partly second and partly fourth declension).

Fifth Declension: *-e* stems.

All nouns in this declension have nominative in *-es*, and are feminine (except *dies*, which is common gender in singular, and masculine in plural).

	Singular.	*Plural.*
N. V	dies (*day*)	dies.
Acc.	diem	dies.
Gen.	diei	dierum
Dat.	diei	diebus
Abl.	die	diebus

Pronouns — Personal: (purely substantives).

First Person

	Singular.	*Plural.*
Nom.	ego, *I*	nos, *we*
Acc.	me, *me*	nos, *us*
Gen.	mei, *of me*	*nostri, *or* nostrum, *of us*
Dat.	mihi, *to* or *for me*	nobis, *to* or *for us*
Abl.	me, *by me, etc.*	nobis, *by us, etc.*

Second Person

	Singular.	*Plural.*
Nom.	tu, *thou*	vos, *ye*
Acc.	te, *thee*	vos, *you*
Gen	tui	*vestri *or* vestrum
Dat.	tibi	vobis
Abl.	te	vobis

* Note. *Nostrum* and *vestrum* are *Partitive* genitives—that is, used in phrases like "many of us" (*multi nostrum*), "two of you" (*duo vestrum*), where the genitive stands to the nominative in the relation not of a possessor, but of a whole to a part. But "love of us" would be *amor nostri.*

Third Person

For *he, she, it*, the Demonstrative Pronouns *hic*, *is*, or *ille* (see below) are used. Thus, masculine *hic* (he), feminine *haec* (she), neuter *hoc* (it).

Demonstrative. Used either as adjectives or substantively: thus (1) *hic puer* = this boy, (2) *hic* = he.

1. Simple or Unemphatic.

Singular.

	Masc.	*Fem.*	*Neut.*
Nom.	is (*that*, or *he*)	ea (*she*)	id (*it*)
Acc.	eum	eam	id
Gen.	ejus	ejus	ejus
Dat.	ei	ei	ei
Abl.	eo	ea	eo

Plural.

Nom.	ii	eae	ea
Acc.	eos	eas	ea
Gen.	eorum	earum	eorum
Dat.	iis *or* eis (*all genders*)		
Abl.	iis *or* eis		

2. Emphatic

Hic, this (near me): the demonstrative pronoun of the first person.

Singular.

Nom.	hic	haec	hoc
Acc.	hunc	hanc	hoc
Gen.	hujus		
Dat.	huic		
Abl.	hoc	hac	hoc

Plural.

Nom.	hi	hae	haec
Acc.	hos	has	haec
Gen.	horum	harum	horum
Dat.	his		
Abl.	his		

Iste, that (near you): the demonstrative pronoun of the second person. (Often used contemptuously—*e.g.*, *isti* = those contemptible friends of yours. In law, *hic* = my client, *iste* = my opponent, the defendant.)

Singular.

Nom	iste	ista	istud
Acc.	istum	istam	istud
Gen.	istius		
Dat.	isti		
Abl.	isto	ista	isto

Plural.

Nom.	isti	istae	ista
Acc.	istos	istas	ista
Gen.	istorum	istarum	istorum
Dat.	istis		
Abl.	istis		

Ille, that (near him): the demonstrative pronoun of the third person = that yonder, that out there. (Often means "the distinguished": *Cato ille* = the great Cato.) Declined like *iste*.

Definitive.

Idem, the same: (compound of *is* and *dem*.)

Singular.

	Masc.	*Fem.*	*Neut.*
Nom.	idem	eadem	idem
Acc.	eundem	eandem	idem
Gen.		ejusdem	
Dat.		eidem	
Abl.	eodem	eadem	eodem

Plural.

Nom.	eidem	eaedem	eadem
Acc.	eosdem	easdem	eadem
Gen.	eorundem	earundem	eorundem
Dat.		eisdem	
Abl.		eisdem	

Ipse, self. Declined like *ille*, except that the neuter sing. nom. and acc. is not *ipsud*, but *ipsum*. Examples of its use: *ego ipse* = I myself; *illo ipso die* = on that very day. It can be used of any person (with *ego*, *tu*, etc.) and in any case.

Reflexive. (Third Person.)

Singular and Plural.

Nom.	(wanting: use *ipse* for "he himself.")
Acc.	se (*or* sese), *himself, herself, itself, themselves.*
Gen.	sui, *of himself*, etc.
Dat.	sibi, *to* or *for himself*, etc.
Abl.	se (*or* sese), *with himself*, etc.

Possessive.

Singular.

	Masc.	*Fem.*	*Neut.*	
1*st person*	meus	mea	meum	(*my, mine*)
2*nd person*	tuus	tua	tuum	(*thy, thine*)
3*rd person* (*Reflexive only*)	suus	sua	suum	(*his own, her own, etc.*)

Plural.

1*st person*	noster	nostra	nostrum	(*our*)
2*nd person*	vester	vestra	vestrum	(*your*)
Also	cujus	cuja	cujum	(*whose*)

Decline *meus, tuus, suus*, and *cujus* like *bonus*; *noster* and *vester* like *niger*. *Meus* has vocative masc. *mi*; *tuus* and *suus* have none.

NOTE. *Suus* is reflexive only, and cannot be used for the ordinary possessive of the third person. *Se* and *suus* can only be used when the person they denote is the same as the nominative to the principal verb in the sentence in which they occur, as "Brutus killed *himself* (*se*) with *his own* (*suo*) dagger." For the ordinary third person possessive use genitive of *is, hic*, or *ille*; thus, *sumus ejus servi* = we are his slaves.

Verbs. Latin verbs, like English, have two voices, Active and Passive; two numbers, singular and plural; and three persons in each number, thus 1st pers. *amo*, I love; 2nd, *amas*, thou lovest; 3rd, *amat*, he loves. Note that the pronouns *ego, tu*, etc., are not expressed, but are implied by the different personal endings.

SCHEME OF THE FOUR CONJUGATIONS.

[*Must* be learnt by heart.]

There are four regular Conjugations:

Conjugation.		*Pres. Indic.*	*Infinitive.*	
1*st*	*A-verbs*	amo	amA-re	*I love*
2*nd*	*E-verbs*	moneo	monĒ-re	*I warn*
3*rd*	*Consonant or U-verbs*	rego induo	reG-ĕre indU-ĕre	*I rule* *I put o*[n]
4*th*	*I-verbs*	audio	audI-re	*I hear*

Active Voice.

Indicative Mood.

	Singular.			*Plural.*	
	1*st person*	2*nd*	3*rd*	1*st*	2*nd*	3*rd*

PRESENT.

Am-o	as	at	amus	atis	ant
(*I love, or am loving, etc.*)					
Mon-eo	es	et	emus	etis	ent
(*I warn, or am warning, etc.*)					
Reg-o	is	it	ĭmus	ĭtis	unt
(*I rule, or am ruling, etc.*)					
Aud-io	is	it	imus	itis	iunt
(*I hear, or am hearing, etc.*)					

FUTURE SIMPLE.

Amā- Monē- } bo	bis	bit	bimus	bitis	bunt
(*I shall love, or warn, etc.*)					
Reg- Audi- } am	es	et	emus	etis	ent
(*I shall rule, hear, etc.*)					

IMPERFECT.

Ama- Monē- Regē- Audiē- } bam	bas	bat	bamus	batis	bant
(*I was loving, etc.*)					

PERFECT.

Amav- Monu- Rex- Audiv- } i	isti	it	imus	istis	ērunt (*or* ēre)
(*I have loved, or I loved, etc.*)					

FUTURE PERFECT.

Amav- Monu- Rex- Audiv- } ero	eris	erit	erimus	eritis	erint
(*I shall have loved, etc.*)					

PLUPERFECT.

Amav- Monu- Rex- Audiv- } eram	eras	erat	eramus	eratis	erant
(*I had loved, &c.*)					

Subjunctive Mood.

PRESENT.

Am-em	es	et	emus	etis	ent
Mon-eam	eas	eat	eamus	eatis	eant
Reg-am	as	at	amus	atis	ant
Aud-iam	ias	iat	iamus	iatis	iant

IMPERFECT.

Ama- Monē Regĕ- Audi- } rem	res	ret	remus	retis	rent

	Singular.			*Plural.*	
	1st person	*2nd*	*3rd*	*1st*	*2nd*	*3rd*

PERFECT.

Stems	1st	2nd	3rd	1st	2nd	3rd
Amav- Monu- Rex- Audiv-	erim	eris	erit	erimus	eritis	erint

PLUPERFECT.

Stems	1st	2nd	3rd	1st	2nd	3rd
Amav- Monu- Rex- Audiv-	issem	isses	isset	issemus	issetis	issent

Imperative Mood.

PRESENT TENSE—

2nd sing.	*2nd plural.*
Ama (*love thou*)	Amate (*love ye*)
Monē	Monete
Regĕ	Regite
Audi	Audite

FUTURE TENSE—

2nd sing.	*3rd sing.*	*2nd pl.*	*3rd pl.*
amato	amato	amatote	amanto
(*thou must love, &c.*)			
moneto	moneto	monetote	monento
regito	regito	regitote	regunto
audito	audito	auditote	audiunto

Infinitive Mood.

PRES. AND IMPERF.		PERF. AND PLUPERF.	
ama- monē- regĕ- audi-	rĕ (*to love, &c.*)	amav- monu- rex- audiv-	isse (*to have loved, &c.*)

Gerund (VERBAL NOUN).

	Nom. and Acc.	*Gen.*	*Dat. and Abl.*
amand- monend- regend- audiend-	um	i	o

Participles.

PRESENT.	FUTURE.
amans, *loving*	amaturus, a, um
monens	moniturus, a, um
regens	recturus, a, um
audiens	auditurus, a, um

Supines.

amatum	amatu
monitum	monitu
rectum	rectu
auditum	auditu

NOTE. The Gerund and the two Supines are verbal nouns or substantives, supplying cases to the infinitive: thus, *spes regendi* (genitive of the gerund *regendum*) = the hope of ruling; *mirabile auditu* (abl. of supine) = wonderful to hear.

The participles are verbal adjectives, and are declined as such: future participles like *bonus*, present participles like *ingens* (see next lesson).

The present, perfect, and supine stems must be known in order to conjugate a verb; from these the other parts of the verb may be formed. Therefore it is well to learn what are called the Principal Parts of every verb: that is, the present infinitive, the perfect indicative, and the supine in -*um*. Thus of *amo* the principal parts are *amare, amavi, amatum*. The following table will be found useful for reference, showing how all the tenses (both active and passive) are derived from these three principal parts:

DERIVATION OF THE VERB FORMS.

From Present Infinitive stem.

Pres. act. and pass.	Infin. pres. a. and p.
Fut. simple a. and p.	Gerund and gerundive
Imperf. a. and p.	Participle pres. act.
Imperative a. and p.	

From Perfect stem.

Perfect active	Pluperfect active
Fut. perf. active	Infin. perf. active

From Supine stem.

Supines	Perfect pass.
Fut. part. act.	Future perf. pass.
Fut. infin. pass.	Pluperf. pass.
Perf. part. pass.	Perf. Infin. pass.

Notice that the Imperative Active is formed by dropping the *re* from the Present Infinitive: *amare, ama; audire, audi*, etc.

Note also: The Present, Future, and Present Perfect (*i.e.* "*amavi*" translated "I have loved," not "I loved") are called *Primary* tenses; the Imperfect, Pluperfect, and simple Perfect ("*amavi*," "I loved"), Historic tenses.

SECTION II. SYNTAX.

RULE 1. If one verb is predicated of two or more subjects, it will be in the plural—*e.g., Puer et puella equum amant* = the boy and the girl love the horse.

RULE 2. If there are two or more subjects of different grammatical persons, the verb agrees with the first person rather than the second, and with the second rather than the third—*e.g., Si tu et Tullia valetis, ego et Cicero valemus* = if you and Tullia are well, Cicero and I are well. [NOTE. The Romans put "I" first: they said, "*ego et Caius*," where we say, "Caius and I." Therefore when Wolsey wrote "*Ego et rex meus*," he was a good scholar, though a poor courtier.]

RULE 3. When an adjective qualifies nouns of different genders, it agrees with the masculine rather than with the feminine—*e.g., Frater mihi* (or *meus*) *et soror mortui sunt* = my brother and sister are dead. If the subjects are all lifeless things, no matter what their gender, the adjective is neuter—*e.g., Divitiae et gloria jucunda* (neut. pl.) *sunt* = riches and glory are pleasant.

SENTENCES TO BE PUT INTO LATIN.

Both ... and—Et ... et.	**Therefore**—Ergo.
Wind—Ventus, -i.	**Money**—Pecunia.
Storm—Procella.	**I show**—Monstro, -are.
Dream—Somnium.	**Wisdom**—Sapientia.
Experience—Experientia.	**Many**—Multi (*pl.*).
I hope—Spero, -are.	**I blame**—Culpo, -are.
Too much—Nimis.	**Deed**—Factum.
Less—Minus.	**I lead**—Duco, ducere.
I give—Do, dare, dedi, datum.	**Desired**—Optatus, -a, -um.
I say—Dico, dicere, dixi, dictum.	**Haven**—Portus, -ûs.

1. God rules both the winds and the storms.
2. This thing (omit "thing," and put "this" in neuter) is not the same as (*ac*) that, and never (say "nor ever," *neque unquam*) will be.
3. In (his) dreams he heard himself warning his friends.
4. Experience warns us not (use *ne* with subjunctive mood, negative of *ut*) to hope too much.

5. If she had loved (subjunctive) herself less, she would have been happy.

6. Both you and I will warn this boy not to give (his) books to that poet (say, as in No. 4, "that he may not give," using *ne*).

7. Cæsar himself has said it: therefore it is true.

8. Love glory and not money: so (*ita*) shalt thou show true wisdom.

9. Many of us will blame you on account of this day's deeds.

10. Through waves and storms God leads us to the desired haven.

KEY TO THE ABOVE SENTENCES.

1. Deus et ventos et procellas regit.
2. Hoc non est idem (*neut.*) ac illud, neque unquam erit.
3. In somniis se audivit amicos monentem (*acc. of present participle, agreeing with* se).
4. Experientia nos monet ne nimis speremus.
5. Si se (*or* ipsam) minus amavisset, fuisset beata.
6. Et ego et tu hunc puerum monebimus ne libros illi poetae det.
7. Caesar ipse hoc dixit: ergo verum est.
8. Ama gloriam, non pecuniam: ita veram sapientiam monstrabis.
9. Multi nostrum te (*or* vos) ob hujus diei facta culpabimus.
10. Per undas et procellas (*or* procellasque) Deus nos ad optatum portum (*not* dative) ducit.

SECTION III. TRANSLATION.

VOCABULARY.

Monumentum, -i—A monument.
Quaero, -ere—I seek.
Circumspicio — I look round.
Regnum—A kingdom.
Mundus, -i—World.
Minister, -ri—Servant.
Certo, -are—I strive.
Alius, -a, -um—Other.
Laudo, -are—I praise.
Recipio, -ere—I receive.
Visus, -ûs—Sight.
Fides, -ei—Faith.
Servo, -are—I save.
Regno, -are—I reign.
Sed—But.
Dormio, -ire—I sleep.
Ambulo, -are—I walk.
Seculum—Generation.
Venio, -ire—I come.
Voluntas — Will (*Nominative*).
Sicut—As.
Caelum—Heaven.
Terra—Earth.

SENTENCES TO BE TRANSLATED INTO ENGLISH.

1. Si monumentum quaeris, circumspice.
2. Regnum meum non est ex hoc mundo: si ex hoc mundo esset regnum meum, ministri mei certavissent.
3. Multi alios laudant, ut ab illis laudentur (*pres. subj. passive of* "laudo").
4. Et Jesus dixit ei, Recipito visum: fides tua te servavit.
5. Nero post Tiberium, sed ante Vespasianum regnavit.
6. Dormiens ambulabat.
7. Amavisse non idem est ac amare.
8. Illi (*dat. sing.*) sit gloria in secula seculorum.
9. Veniat regnum tuum; fiat (= *let be done*) voluntas tua, sicut in caelo, ita etiam in terra.
10. Ama hanc puellam, sed mone illum puerum ne stultus (*foolish*) sit.

KEY TO THE ABOVE SENTENCES.

1. If you seek a monument, look around.
2. My kingdom is not of (literally "from") this world; if my kingdom were of this world, my servants would have striven (*si* usually takes subjunctive).
3. Many men praise others, in order that they may be praised by them.
4. And Jesus said to him, Receive (thy) sight: thy faith has saved thee.
5. Nero reigned after Tiberius, but before Vespasian.
6. He used to walk (note the force of the imperfect) in his sleep (literally "sleeping," pres. part. of *dormio*).
7. "To have loved" is not the same (thing) as "to love."
8. To him be the glory for generations of generations (a frequent use of *in* = during, for).
9. Let thy kingdom come: let thy will be done, as in heaven, so also on earth.
10. Love this girl, but warn that boy not to be foolish (that he may not be; *ne* is negative of *ut*, which = in order that).

To be continued

ENGLISH

By Gerald K. Hibbert, M.A.

Number. In English there are only two numbers, Singular and Plural. A noun is said to be Singular when it denotes a single object, and Plural when it denotes two or more things of the same kind—*e.g.*, *book*, *books*.

The plural is formed from the singular in several ways.

1. By far the commonest method is to add *es* (Anglo-Saxon *as*) to the singular: this becomes *s* when the pronunciation admits of it.

a. The full syllable *es* is added only when the singular ends in a sound of *s*—*i.e.*, *s sh*, soft *ch*, *x*, *z*. Examples: *churches*, *foxes*, *lashes* (but *monarchs*).

b. The letters *es* are also added after several words ending in *-o* (*cargoes*, *potatoes*), and one in *-i* (*alkalies*); but they are not sounded as a separate syllable in this or the two following cases. (A few words in *-o* simply add *-s*, as *solo*, *tyro*, *canto*, *grotto*, *quarto*, *octavo*, and all in *-io* and *-oo*.)

c. *-es* is also added after *y* preceded by a consonant, the *y* being changed to *i*: *body, bodies*. *Qu* counts as a consonant: *soliloquy, soliloquies*. But if a vowel precedes the *y*, *-s* alone is added, the *y* remaining unchanged—*e.g., chimneys, boys, moneys* (avoid the spelling *monies*).

d. *-es* is also added to words of Anglo-Saxon origin ending in *f, fe*, and *lf*, preceded by any long vowel sound except *oo*, and the *f* is changed into *v*. Examples: *life, lives*; *calf, calves*; *loaf, loaves*. But nouns in *oof, ff, rf*, and nouns in *f* of Norman-French origin, take simple *-s*, and retain the sharp sound of the *f*—*e.g., chiefs, roofs, skiffs, turfs, reefs*.

NOTE: *thief, thieves*; *staff, staves*; *wharf, wharves*; *scarf, scarves*.

All other nouns except those to be immediately mentioned add *s* to the singular—*e.g., cats* (sharp *s*), *dogs* (flat *s*).

2. By adding *-en*, as *ox, oxen*; *brother, brethren*; *child, children* ("children" is a double plural, the old English plural being "childer"); *eye, eyne* (Spenser, Shakespeare); *shoe, shoon*; *cow, kine*; *hose, hosen*.

3. By changing the vowel sound of the word, as *man, men*; *foot, feet*; *mouse, mice*; *tooth, teeth*. To this head also belong *brethren* and *kine*, as well as to 2.

4. By leaving the singular unchanged—*e.g., sheep, deer, swine*. *Cf.* also: twenty *brace* of partridges, ten *thousand* horse (*i.e.* cavalry), ten *sail* of the line.

DOUBLE PLURALS. Some nouns have two plurals, differing in meaning.

Brother	Brothers (*by birth*)	Brethren (*of a society*)
Die	Dies (*for stamping*)	Dice (*for play*)
Penny	Pennies (*separate coins*)	Pence (*lump sum*)
Index	Indexes (*of a book*)	Indices (*in Algebra*)
Pea	Peas (*separate seeds*)	Pease (*collective*)
Genius	Geniuses (*gifted men*)	Genii (*spirits, ghosts*)
Cloth	Cloths (*kinds of cloth*)	Clothes (*garments*)

NOUNS USED ONLY IN SINGULAR. Names of materials or substances, and of qualities: as *water, gold, humour*. These nouns can, of course, take a plural, denoting different sorts of the same thing—*e.g., mineral waters*.

NOUNS USED ONLY IN PLURAL. Names of instruments or articles of dress made double (*scissors, trousers*); portions of the body, diseases, games, ceremonies, etc. (*entrails, mumps, billiards, matins*).

NOUNS IN SUSPENSE BETWEEN SINGULAR AND PLURAL. *Alms* (Old English *aelmesse*), *riches* (French *richesse*), and *eaves* (Old English, *efese*) are really singular, though often treated as plural—*e.g.*, "Who asked *an* alms"; "Riches fineless [endless] *is* as poor as winter, To him that ever fears he shall be poor."

Amends, means, news, pains, wages, are strictly plural, but are often used as singular—*e.g.*, "The wages of sin is death"; "A means to an end"; "To make an amends." *News* is now always singular: "Ill news flies apace" (*cf.* "These ill news," in Shakespeare).

Small-pox is strictly a plural, from singular *pock*.

PLURALS OF COMPOUND NOUNS. In most compounds the constituent parts have so completely coalesced that there is no difficulty about forming the plural in the ordinary way—*e.g., rain-bow, rain-bows, horse-box, horse-boxes*.

But compounds of a noun and an attributive word or phrase, in which the parts have not coalesced into a single word, add the *-s* to the noun—*e.g., courts-martial, knights-errant, fathers in-law*. When the compound consists of *two nouns* imperfectly coalesced both take the sign of the plural—*e.g., knights-templars, men-servants, lords-lieutenants, lords-justices*.

PLURALS OF FOREIGN WORDS. A number of nouns borrowed from foreign languages retain their proper plurals. Thus:

LATIN.

Nouns in *a*	make *æ*:	nebula, nebulæ
„ *um*	„ *a*:	erratum, errata
„ *is*	„ *es*:	axis, axes
„ *ix* (*ex*)	„ *ices*:	vertex, vertices; appendix, appendices
„ *us* (masc.)	„ *i*:	terminus, termini
„ *us* (neut.)	„ *era*:	genus, genera
„ *ies*	„ *ies*:	series, series

GREEK.

Nouns in *on*	make *a*:	phenomena, automata
„ *sis*	„ *ses*:	crises, parentheses
„ *ma*	„ *mata*:	miasmata

MISCELLANEOUS. Cherub, cherubim; seraph, seraphim; beau, beaux; madame, mesdames; bandit, banditti; virtuoso, virtuosi.

Case. Cases are the different forms which a Noun or Pronoun assumes to denote its relation to other words in a sentence. In Modern English we have three cases, *Nominative, Possessive, Objective*.

In Anglo-Saxon there were five cases, as in Latin—Nominative, Genitive, Dative, Accusative and Instrumental (or Ablative). The last was retained only in pronouns and dropped in nouns; the Dative gradually came to be used for the Accusative as well as for itself, and was called the Objective. The Possessive represents the old Genitive.

The *Nominative* is the case of the Subject of the sentence, and denotes the person or thing about which we are speaking. It answers the question *Who?* or *What?*—*e.g.*, "Time flies." When the Nominative names the person spoken *to*, rather than *of*, it is called the Nominative of Address, or sometimes the Vocative (*voco* = I call)—*e.g.*, "*Son*, go work in my vineyard."

The *Possessive* is the Case by which we show that something belongs to the person or thing for which it stands—*e.g.*, "Joseph's brethren." It is the only case in nouns in which a case suffix is now used. The Possessive Case in the

singular, and in those forms of the plural not ending in *s*, is formed by adding *'s* to the nominative case—*e.g.*, "Women's rights." But when the plural ends in *s*, the possessive is indicated in writing by putting the apostrophe after the *s*, as "boys' clothes."

NOTE. The use of the apostrophe is modern. The old Possessive suffix was *es* (seen in Wednesday—*i.e.*, Wodenes day), and the apostrophe shows that the *e* has been dropped. The *'s* is *not* an abbreviation of *his*: so "For Jesus Christ His sake" is incorrect.

The simple apostrophe is sometimes used with singular nouns that end in an s sound—e.g., for justice' sake; for righteousness' sake. This is admissible, but we must write "Chambers's Journal," not "Chambers' Journal," for we do not omit the *'s* in speaking.

In the case of a complex name, the possessive suffix is attached only to the last word of the name—*e.g.*, "The Prince of Wales's carriage"; "With Mr. and Mrs. Brown's compliments."

The *Objective* Case is that form of a noun (or pronoun) which denotes that the noun or pronoun stands for the object of the action indicated in some verb in the active voice, or which comes after a preposition. A noun is therefore in the Objective Case when it is the object of a verb or is governed by a preposition. The Objective Case answers the question "*Whom? What?*" In Nouns the Objective Case is the same in form as the Nominative; usually, therefore, we distinguish the two by their position in the sentence, the Nominative coming before the verb, and the Objective after—*e.g.*, "Manners (nom.) maketh man (obj.)"; "Daniel (nom.) was in the den (obj. after *in*) of lions."

The Objective, besides representing the Latin accusative (direct object, as above), also represents the Latin dative (indirect object, *to* or *for*) —*e.g.*, "Tell me the old, old story," where *me* is indirect and *story* direct object; "Saddle *me* the ass"; "He answered *him* never a word"; "He plucked *me* (for me) ope his doublet"; "Knock *me* (for me) at this gate."

Syntax of the Noun. The Syntax of the noun deals with the manner in which a noun is related to the other words in a sentence.

NOMINATIVE CASE.

1. Complementary Nominative. The verbs *to be, to become*, and Passive verbs of *naming, making, appointing, deeming*, &c., take a nominative after them as well as before: "Is it *I*?"; "John the Baptist is called *the Elijah* of the New Testament." In colloquial language we say, "It's me," "That's him," but such expressions are incorrect.
2. Nominative Absolute (corresponding to Ablative Absolute in Latin, and Genitive Absolute in Greek). The Nominative may be used with a Participle, forming with it a clause *grammatically* independent of the rest of the sentence, *i.e.* an *absolute* clause —*e.g.*, "They pressed on into the heart of the mountains, *the scenery becoming more and more sombre at every step*." This sentence is complete grammatically, even if we omit the words in italics. Similarly, in "Paradise Regained:"

   "And when to all his angels he proposed
   To draw the proud king Ahab into fraud,
   That he might fall in Ramoth, *they demurring*,
   I undertook that office."

   The participle is sometimes omitted: "Yet he himself, *time to himself best known*, Remembering Abraham, etc." ("Paradise Regained"), where "being" is omitted before "best known."

POSSESSIVE CASE. This is rarely used except where the Noun denotes a living thing: in such expressions as "the cannon's mouth," "the Church's one foundation," the objects are personified. Traces of the old genitive case (which the Possessive replaced) are seen in "a month's notice," "a day's wages," "at their wit's end."

In familiar language the Possessive is often used alone, without the noun on which it depends: as "St. Paul's" (Cathedral), "Prince's" (Restaurant), "a poem of Tennyson's."

OBJECTIVE CASE.

1. The Objective usually follows the verb, but when it differs in form from the Nominative it may stand before the verb, without causing any ambiguity: as "He saved others: *himself* he cannot save."
2. Verbs of *making, appointing, calling, thinking* take a *Complementary Object* in addition to the direct object: as, "They hailed him (direct) father (compl. obj.) of a line of kings."
3. The verbs *ask, teach, forgive, banish*, etc., often take a second Objective—*e.g.*, "We banish you our territories"; "I ask you pardon." These verbs can take an Objective even in the Passive Voice: "He was denied his rights."
4. The Cognate Objective, or Objective of kindred meaning, is used after many *intransitive* verbs: "I have fought the good fight"; "He laughed his great laugh." There is, of course, here a transitive force in the verb.
5. The Objective is used after intransitive verbs and after adjectives to denote extent, duration, age, value: as "The plain stretched *miles* in each direction."
6. The objective is used after certain old Impersonal Verbs, when it is the virtual, though not the grammatical subject—*e.g.*, "It repenteth *me* that I have set up Saul to be king" (= I repent).

APPOSITION. When two or more nouns are used together, as names of the same thing, they are said to be in Apposition; they are always of the same *case*. "So hand in hand they passed, *the loveliest pair*" (nominative).; "We have found him of whom Moses . . . did write, *Jesus of Nazareth*" (objective).

Sometimes a Noun stands in apposition to a whole sentence: "They dragged her away shrieking, *a sight* to move the hardest heart."

CORRECT THE FOLLOWING SENTENCES:

1. The boy stood on the burning deck,
   Whence all but he had fled.
2. Whom do men say that I am?
3. This injury has been done me by my friend, he whom I treated like a brother.
4. Oh, a cherubim thou wast that did preserve me.
5. Where nothing save the waves and I
   Shall hear our mutual murmurs sweep.

To be continued

GERMAN

By P. G. Konody and Dr. Osten

THE German and English languages are connected by descent. The English is derived from the Old Saxon, one of the branches of the ancient Teutonic languages.

But historical influences, principally the influx of Latin elements due to the Norman Conquest, and the self-acting processes of natural development, have extensively altered the English language. By suppressions, insertions, inflections and manifold other alterations, phonetic and structural, the English language has performed her individualisation. The two languages reveal at present only superficial affinities, and differ fundamentally in the pronunciation, as well as in the rules of transformation, in the different categories of words which, according to the modifications of quantity, gender, and tense, have to be produced.

One of the most remarkable differences may be noticed in the intensity of sound needed for forming German and English words. German sounds far louder than English, as may be easily perceived by anybody frequenting some German assembly. This phenomenon is due to the fact that the German produces his words in the middle and at the back of his mouth, whilst English words are produced in the front. The difference is, of course, due to the nature of the sounds themselves, which in German comprise gutturals and compounds unknown in English.

The principal objects the English student of German ought to keep in view at the beginning are the careful study of the pronunciation, and the regular and constant enlargement of his stock of German words. The German language contains an enormous number of words, and the perfect command of a certain amount of vocables, gradually extended according to the general progress, seems indispensable.

As regards the German pronunciation, the student should not be discouraged by the initial difficulties, which consist mainly in producing sounds which have no equivalent in English. Once he has mastered these sounds, all will be plain sailing, as every letter has practically only one pronunciation, and every written or printed letter is clearly sounded. Such variations in the pronunciation of the same letters in English, as the *a* in ball, have, far, dance; or the *ough* in rough, plough, cough, dough, thorough, and through, could never occur in German. The student should make it a point from the very beginning to practise the clear, clean pronunciation of the German vowels, which must be conceived as strictly isolated sounds, while in English they are frequently toned down, a very slight *y* being sounded after the *e*, or a *u* after the *o*.

To each explanation in the following chapters the necessary instances are given of selected vocables, which must be learnt by heart and recapitulated daily. Moreover, the student will find abundant practice in translations from one language into the other. The length of the vowels, and the stress which has to be laid on decisive syllables, or words, in compounds, are indicated by separate signs. The principal rules must, of course, be thoroughly remembered, as well as the main features of the numerous exceptions, of which the complete command can only be acquired by practical experience.

An examination paper, with a key, will be given at the end of each lesson.

PRONUNCIATION.

Signs used for indicating the pronunciation: Long, ¯; short, ˘; very short, °; stress, ʹ; division of syllables and of compound words, -.

THE PRINTED LETTERS (TYPES).—The German types are cut in the characteristic Gothic style, and differ from the Latin types used in the English language by their pointed shape, but the difference is in some cases very slight. The following small letters can be easily recognised by their close similarity with their Latin equivalents:

Latin types: b, c, e, g, i, j, l, m, n, o, p, q, r, s,
German types: 𝔟, 𝔠, 𝔢, 𝔤, 𝔦, 𝔧, 𝔩, 𝔪, 𝔫, 𝔬, 𝔭, 𝔮, 𝔯, 𝔰,

Latin types: t, u, w, y;
German types: 𝔱, 𝔲, 𝔴, 𝔶.

The other letters of the small alphabet appear somewhat differently shaped:

Latin types: a, d, f, h, k, s, v, x, z;
German types: 𝔞, 𝔡, 𝔣, 𝔥, 𝔨, ſ, 𝔳, 𝔵, 𝔷.

The capitals show essentially distinctive forms, except those of rotund character—D, O, Q, U.

Latin Capitals: A, B, C, D, E, F, G, H, I,
German Capitals: 𝔄, 𝔅, ℭ, 𝔇, 𝔈, 𝔉, 𝔊, ℌ, ℑ,

Latin Capitals: J, K, L, M, N, O, P, Q, R,
German Capitals: 𝔍, 𝔎, 𝔏, 𝔐, 𝔑, 𝔒, 𝔓, 𝔔, ℜ,

Latin Capitals: S, T, U, V, W, X, Y, Z;
German Capitals: 𝔖, 𝔗, 𝔘, 𝔙, 𝔚, 𝔛, 𝔜, ℨ.

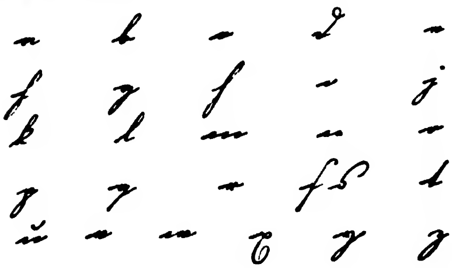
The letters of German handwriting differ greatly from the printed Gothic types; but though a knowledge of them will be found distinctly useful, it is not absolutely essential, as everybody in Germany is able to read Latin characters, which are now frequently used in writing. It will therefore only be necessary for the student to be able to *read*, not to write German handwriting. Even in printing, the use of Latin type is spreading more and more in Germany, especially in works of science and in the economic part of newspapers.

Beware of confounding the following very similar letters:

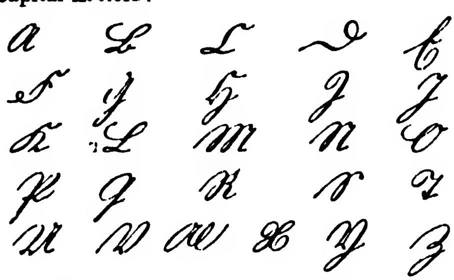
𝔟 and 𝔥; 𝔠 and 𝔢; 𝔣 and ſ; 𝔫 and 𝔲; 𝔬 and 𝔳; 𝔯 and 𝔵; 𝔅 and 𝔙; 𝔑 and ℜ; 𝔐 and 𝔚.

THE ALPHABET OF GERMAN HANDWRITING.

Small Letters:



Capital Letters:



To facilitate the knowledge of German type, some of the following explanations in English are partly printed in German type.

THE GERMAN ALPHABET.

Each of the German vowels has but one pronunciation, varying only in length. Thus the German 𝔄, 𝔞, is *always* pronounced *as in father*, though in certain words the sound is shorter. It varies in quantity, but not in quality. The same rule is to be observed with the other simple vowels —𝔢, 𝔦, 𝔬, 𝔲.

The simple consonants are on the whole pronounced as in English, except the ℭ, 𝔠 (like *ts* in *bits*); the 𝔊, 𝔤 (like *g* in *go*); the ℜ, 𝔯, which is more rattling than in English; the 𝔙, 𝔳 (generally like *F, f*); the 𝔚, 𝔴 (like the English *V, v*); and the ℨ, 𝔷 (like *ts* in *bits*). The 𝔖, 𝔰 is pronounced sharp or soft, according to its position in the word.

The simple vowels 𝔞, 𝔬, and 𝔲 are subject to modification, this modification being indicated by ʺ above the vowel—𝔞̈, 𝔬̈, 𝔲̈. Letters thus marked are pronounced differently, and are generally used to express changes in the number, tense, degree, and volume (diminutives) of different classes of words.

The *double vowels* (with few exceptions) and the double consonants are pronounced as if they were simple, only the former long, the latter sharper. By doubling the consonant the preceding vowel becomes short.

In German all letters are pronounced, except the 𝔢 after 𝔦, and the 𝔥 after any vowel at the end of a word, or between a vowel and a consonant. In such cases the 𝔢 and 𝔥 are not to be considered, strictly speaking, as letters, but merely as signs to indicate the lengthening of the preceding vowel. Another case where the 𝔥 is not pronounced is after 𝔱, in such words as Theil (part), which is pronounced "tile"; but the practice of introducing it in this position is being gradually abandoned, so that in all modern books the word is spelt Teil.

The exact pronunciation of the whole alphabet, the principal rules, exceptions, and examples, will be found in the following tables, which the student is emphatically advised to read repeatedly, until he has completely mastered them.

TABLE I.

Latin.	German Print.	German Name.	Pronunciation.	Latin.	German Print.	German Name.	Pronunciation.
A a	𝔄 𝔞	Āh	As a in *fäther*.	N n	𝔑 𝔫	Ĕn	No difference.
B b	𝔅 𝔟	Bēh	Bay.*	O o	𝔒 𝔬	Oh	As in *short*.
C c	ℭ 𝔠	Tsēh	Tsay.*	P p	𝔓 𝔭	Pēh	Pay.*
D d	𝔇 𝔡	Dēh	Day.*	Q q	𝔔 𝔮	Kvēh or Kōō	Kvay or Koo.
E e	𝔈 𝔢	Ēh	Like the a in *fate*.	R r	ℜ 𝔯	Ĕrr	As in *berry*.
F f	𝔉 𝔣	Ĕff	As in *effort*.	S s	𝔖 ſ 𝔰†	Ĕss	No difference.
G g	𝔊 𝔤	Gēh	Gay.*	T t	𝔗 𝔱	Tēh	Tāy.*
H h	ℌ 𝔥	Hāh	The h aspirated, the a as in *fäther*	U u	𝔘 𝔲	Oo	As in *bōōt*.
I i	ℑ 𝔦	Ēe	As in *bee*.	V v	𝔙 𝔳	Fow	Ow as in *gown*.
J j	𝔍 𝔧	Yŏt	As y in *yăcht* (shorter).	W w	𝔚 𝔴	Vēh	Vay.*
K k	𝔎 𝔨	Kāh	The a as in *fäther*.	X x	𝔛 𝔵	Ĭks	Like ix in *six*.
L l	𝔏 𝔩	Ĕll	No difference.	Y y	𝔜 𝔶	Ypsēēlōn	Y like i pronounced with rounded lips.
M m	𝔐 𝔪	Ĕm	No difference.	Z z	ℨ 𝔷	Tsĕt	Ts as in *nets*.

* Remember to pronounce the vowel clearly, without sounding the slight y, which is merely used in the phonetic spelling as the nearest approach to the actual sound.

† The form 𝔰 is only used at the end of the syllable or word.

TABLE II.

Signs. Above letters and syllables ¯ when long; ˘ when short; ˙ when very short; ′ stress.

Letters.	German Name.	German word.	Pronunciation.	Translation into English.	Rules and Exceptions.
A a 𝔄 𝔞	Āh	𝔊𝔞𝔟𝔢 𝔅𝔞𝔩𝔩 ℌ𝔞𝔫𝔡	Gābĕ Băll Hănt	gift ball hand	The German A a is *always* pronounced as in the English *father* and *arm*, only sometimes long or short.
B b 𝔅 𝔟	Bēh	𝔅𝔞𝔩𝔩 𝔅𝔯𝔲𝔡𝔢𝔯 𝔊𝔯𝔞𝔟	Băll Broodĕr Grāp	ball brother grave	Beh sounds like the English b; at the end of words and prefixes like a mild p.
C c ℭ 𝔠	Tsēh	ℭ𝔢𝔡𝔢𝔯 ℭ𝔞𝔱𝔬 ℭ𝔩𝔞𝔰𝔰𝔢*	Tsāydĕr Kāhtō Klăssĕ	cedar Cato class	The words beginning with tseh are of foreign origin; pronounce like ts before e or i, like k before all other letters.
D d 𝔇 𝔡	Dēh	𝔇𝔲 𝔇𝔬𝔯𝔫 𝔅𝔞𝔫𝔡	Doo ŏ as in short Bănt	thou thorn ribbon	At the end of words like a mild t.
E e 𝔈 𝔢	Ēh	𝔈𝔫𝔤𝔩𝔞𝔫𝔡 𝔈𝔡𝔲𝔞𝔯𝔡 𝔏𝔢𝔟𝔢𝔫	Áynglănt Áydooart Lāybĕn	England Edward life	When short like e in *bet*. When long like a in *fate*.
F f 𝔉 𝔣	Eff	𝔉𝔢𝔡𝔢𝔯 𝔉𝔦𝔰𝔠𝔥	Fāydĕr Fish	feather, pen fish	The sound of f is identical in both languages.
G g 𝔊 𝔤	Gēh	𝔊𝔞𝔯𝔱𝔢𝔫 𝔊𝔢𝔟𝔢𝔫 𝔈𝔴𝔦𝔤	Gărtĕn Gāybĕn Ayvĕech (like ch in *loch*)	garden give eternal	*Always* like the g in *go*; except at end of words—like 𝔠𝔥, but less guttural.
H h ℌ 𝔥	Hāh	ℌ𝔢𝔯𝔷 ℌ𝔬𝔥𝔩 𝔖𝔱𝔯𝔬𝔥	Hărts Hōhl Shtrōh	heart hollow straw	As in English, but before consonants and at the end of words mute, to indicate the long sound of the preceding vowel.
I i ℑ 𝔦	Ee	ℑ𝔠𝔥 ℑ𝔤𝔢𝔩	Eech (softer than ch in *loch*) Eegl	I hedge-hog	I like i in *bill* when short, or like ee in *bee* when long; *never* like i in *mine*.
J j ℑ 𝔧	Yŏt	ℑ𝔞 ℑ𝔢𝔡𝔢𝔯 ℑ𝔬𝔠𝔥	Yāh Yaydĕr Yŏch (like ch in *loch*)	yes every yoke	J *always* like y in *yacht*; *never* like the j in English *jail, jaw*, etc.
K k 𝔎 𝔨	Kāh	𝔎𝔫𝔦𝔢 𝔎𝔞𝔥𝔫 𝔎𝔦𝔯𝔰𝔠𝔥𝔢	˙K-nee Kān Keershĕ	knee boat cherry	K *always* sounds as in *king*; is *never* mute as in *knee, knowledge*, etc.
L l 𝔏 𝔩	Ĕll	𝔏𝔞𝔫𝔡 𝔎𝔩𝔞𝔤𝔢 𝔉𝔞𝔩𝔩	Lănt Klāgĕ Făll	land complaint fall	L as in English, but *always* sounded; it is *never* mute in German as in *half*.

* Now generally spelt 𝔎𝔩𝔞𝔰𝔰𝔢.

TABLE II.—*continued*

Signs. Above letters and syllables ¯ when long; ˘ when short; ° when very short; ′ stress.

Letters.	German Name.	German word.	Pronunciation.	Translation into English.	Rules and Exceptions.
M m 𝔐 𝔪	Ĕm	Mann Magen Mund	Mănn Măghĕn Moont	man stomach mouth	As in English. U as in *pull*.
N n 𝔑 𝔫	Ĕn	Nagel Narr Name	Năghĕl Nărr Nămĕ	nail fool name	As in English.
O o 𝔒 𝔬	Ōh	Ohr Holz	Ōhr Hŏlts	ear wood	As in *stōne* when long, and in *pŏt* when short.
P p 𝔓 𝔭	Pēh	Pelz Politik	Pĕlts Pollytéék	fur politics	As in English.
Q q 𝔔 𝔮	Kvēh, *or* Kōō	Qual Quadrat	Kvāl Kvădrắt	pain, torment square	Q is *always* followed by u.
R r ℜ 𝔯	Ĕrr	Rabe Rolle Herr	Răbĕ Rŏllĕ Hăyrr	raven roll Mister, Sir	More rattling and better audible than the English r, especially the double rr.
S s 𝔖 𝔰 ſ	Ĕss	Salz Rose Gras	Zălts Rōzĕ Grās	salt rose grass	Before vowels like the English z; at the end of syllables and before consonants sharp, as in *slave*.
T t 𝔗 𝔱	Tēh	Tag Hut Nation	Tăch (as in *loch*) ū as in *boot* Nătsiōn	day hat nation	Before the termination ion derived from the Latin, the t is pronounced ts.
U u 𝔘 𝔲	Ōō	Uhr Buch Mutter	ūh as in *boot* ch as in *loch* Mŭttĕr	clock, watch book mother	Like o in *move* when long, and oo in *book* when short.
V v 𝔙 𝔳	Fōw	Vater Volk Vivisektion	Fāhtĕr Fŏlk Vĭvĭsĕktsiōn	father people vivisection	Like the English f, except in words of Latin origin, where the v sounds as in English.
W w 𝔚 𝔴	Vēh	Wille Bewegung	Villĕ Băyvāygŏong	will movement	Like the English v; *never* like w in *will*, *well*, etc.
X x 𝔛 𝔵	Ĭks	Axt Text	Akst Tekst	axe text	As in English.
Y y 𝔜 𝔶	Ўpsēēlŏn	Yacht Martyrium Mystik	(ch as in *loch*) Mărtēēreeōōm Mís-tik	yacht, pinnace martyrdom mysticism	Before a, o and u as in English; in all other cases like e.
Z z ℨ 𝔷	Tsĕt	Zorn Tanz	Tsŏrn Tănts	anger, wrath dance	Like ts in *feats*, *sheets*, etc., *always* sharp.

TABLE III.

Signs. Above letters and syllables ¯ when long; ˘ when short; ˙ when very short; ʹ stress.

Modified Vowels. Letters.	Modified	German word.	Pronunciation.	English Translation.	Rules and Notes.
A a	Ä ä	Ähre ängstlich Käse	Äirĕ ĕngstlēech Käizĕ	ear of corn anxious cheese	When short as e in *bet*; when long like ai in fair.
O o	Ö ö	böse Öl Tölpel	bŏzĕ Ŏl Tŏlpĕl	bad, angry oil dunce, block-head	Almost like the i in *girl* when long; and like e in *tell*, with rounded lips, when short.
U u	Ü ü	Mühle Müller grün Rübe	Mülĕ Mŭller grün Rübĕ	mill miller green turnip	As the French u long. As the French u short.
Diphthongs. Letters.	Compound				
A i a i	Ai ai	Saite Waise Hai	Zitĕ Vīzĕ Hī	string orphan shark	Like the i in *kind*.
A u a u	Au au	Auge Haus grau	g as in *go* Hows	eye house grey	Like ow in *cow*, *gown*, etc.
E i e i	Ei ei	Ei reich verzeihen	I ch as in *loch* fertsĕihĕn	egg rich to forgive	Like the i in *kind*.
E u e u	Eu eu	Eule Treue Heu	Oilĕ Troi-ĕ Hoy	owl fidelity hay	Like oi in *oil*.
Ä u ä u	Äu äu	Bräute Kräuter Gräuel	Broitĕ Kroitĕr Groi-ĕl	brides herbs horror	Like oil in *oil*.
Double Vowels.					
	Aa aa	Haar Paar Saat	 Zaat	hair pair seed	Double vowels sound like the simple vowels, but are always pronounced long. When a prefix ending with an e or o precedes a word beginning with an e or o, the two vowels must be pronounced separately, as in be-einträchtigen, be-einflussen, co-ordination, co-operation, etc.
	ee	Meer See Beere	Mäyr Zäy Bäyrĕ	sea lake berry	
	oo	Loos Boot Moor	Lohs Boht Mohr	lot, allotment boat moor	
	ii	Liniiren	Lēenēeeerĕn	to draw lines on, to rule	Very rare form. These vowels are always pronounced separately. The long i-sound, which would correspond to the aa, ee, oo, is expressed by ie.

TABLE IV.

Signs. Above letters and syllables ¯ when long; ˘ when short; ° when very short; ′ stress.

Compound Consonants.		German word.	Pronunciation.	English Translation.	Rules and Notes.
C h c h	Ch ch	Rache Herrlich Brauch Chemie China Christ Champagner	Rachĕ ch as in *loch* (*see* Notes) ch like k ch like sh	vengeance magnificent custom chemistry China Christian champagne	ch sounds as in the Scotch *loch*; after the vowels e and i and the diphthong ei it has a milder sound, also in some words of foreign origin; in other words it is pronounced like k; in some words, derived from the French, like sh.
c h s	chs	Lachs Sechs	Lăks Zĕks	salmon six	chs sounds like x, except in cases in which ch and s are put together by declension, etc.
c k	ck	Fackel Rock	Făkkĕl Rŏck	torch coat	Like a sharp and short k, used instead of kk.
P f p f	Pf pf	Kopf Pfründe	Kŏpf Pfründĕ	head prebend	In pf both consonants must be audible, though pronounced together.
P h p h	Ph ph	Phantom Philister	Phantŏ́m Philĭ́ster	phantom Philistine	Like f, as in English words of Greek origin.
P ſ p s p ſ	Pſ ps pſ	Psalm Gyps	ps as in *caps* Gĭps	Psalm plaster	The p, s and l well audible.
S c h ſ c h	Sch ſch	Schaf Tasche	Schāf Tăshĕ	sheep pocket	Like the English sh in *shave*.
S p ſ s p	Sp ſp (sp)	Spaß Splitter, Sprung Knospe, Espe	Shpāss Shplittĕr Shprŭng K-nŏspĕ, Ĕspĕ	joke, fun splinter leap bud, asp	When followed by consonants l, r, or vowels, like shp; when preceded by a vowel or between two vowels, like sp in *crisp*, *hospital*.
ſ ſ ſ z	ſſ ß ß=ſz	Masse Blaß, paſſt	Very sharp as in *gossip* and short *a* Sounds like s in *sense* and short *a*	mass, bulk pale (it) suits	ss between two vowels of which the first is short; sz at the end of some words. ss changes into sz in conjugation forms of verbs.
S t ſ t	St ſt	Stock Mast Fürst, Obst	Shtŏck Măst	stick, cane mast prince, fruits	When followed by vowels, like sht. When preceded by vowels, like st. When preceded and followed by vowels, like st. When preceded and followed by consonants r, b, like st.
T h t h	Th th	That rathen	Tāt Rāthĕn	deed, action (to) advise	Always like t; *never* like the English th.
T z t z	Tz tz=zz	Gesetz Tatze	Găyzĕts Tătsĕ	law claw, paw	Sharper than ts in *sheets*. Used instead of zz.
Double Consonants. ff, ck (kk), ll, mm, nn, pp, rr, ſſ, tt, (zz).		Affe, Hölle Kamm, Mann Rippe, Narr Essen, Kette		monkey, hell comb, man rib, fool (to) eat, chain	The double consonants short and sharp.

Beware of pronouncing:

A, a any other way than in *father* (though the sound is at times shorter);

C, c any other way than *ts* in *hats* (except before a, o, and u, when it is pronounced like a k, by which it is now generally replaced);

G, g any other way than in *go*;

I, i any other way than in *bit* (short) and *bee* (long);

Th, th any other way than *t*;

V, v any other way than *F, f* (except in words of Latin origin);

W, w any other way than *V, v*;

Z, z any other way than *ts* in *bits*.

Beware of suppressing, in the pronunciation of words, the letters k, l, and w, which are sometimes mute in English (*knowledge, folk, who*). Mute in German are only the h and e, when used as a means of lengthening the syllable.

Lesson I.

1. How do you pronounce the German I, i ?
2. What is the difference between the English and the German pronunciation of the *th* ?
3. How is the German b pronounced at the beginning and at the end of a word ?
4. Which general rule decides the pronunciation of German vowels ?
5. Is the pronunciation of the *r* alike in German and English ?
6. In how many ways can the German a be pronounced ?
7. Is there a similar sound to the German compound ch in the English language ?
8. How is the German s influenced by the preceding vowels or consonants ? Does the sound of the German s differ according to the position of the letter at the end or in the middle of syllables or words ?
9. To which English sounds does the German c and z bear resemblance ?
10. Is it permissible to pronounce German words containing a w as it is done in *well, will*, etc.
11. To which letter in the English alphabet does the German v correspond ?
12. Which German letters are sometimes mute, and what purpose do they serve ?
13. How is the sound of the German ü produced ?
14. With which English letter does the pronunciation of the German ê correspond, and in which word is the English letter thus pronounced ?
15. How many classes of vowels does the German language contain ?
16. Are the compound consonants always pronounced in the same way ?
17. Which is the pronunciation of the compound consonant sp, when followed by a consonant ?
18. Is there any difference between the pronunciation of the English *f* and the German ?
19. Does the German compound consonant ch always keep its pronunciation, or is it subject to alterations ?
20. Which is the pronunciation of the German ch when followed by s and when preceded by s ?

Examples of Lesson I.

1. Bild, picture ; Insel, isle ; Winter, winter.
2. Thee, tea ; Thron, throne ; Thurm, tower.
3. Bank, bench, bank ; Bibel, bible ; grob, coarse, rude.
4. Mann, man ; Magen, stomach ; Welt, world ; geben, (to) give ; Esel, donkey ; Lippe, lip ; Sieg, victory ; wir, we ; Gott, God ; Bote, messenger ; kurz, short ; gut, good.
5. Ring, ring ; hart, hard ; hurtig, quick ; Trommel, drum.
6. Maler, painter ; Mast, mast.
7. Loch, hole ; lachen, to laugh.
8. Sonne, sun ; Besitz, property ; Gans, goose.
9. Capital, capital ; Citrone, lemon ; Clavier, piano.
10. Wagen, carriage ; Wolf, wolf ; wir, we.
11. Veilchen, violet ; Verachtung, contempt ; Ventil, valve.
12. Muhme, cousin ; Liebe, love.
13. Kühe, cows ; Thüre, door.
14. Hörner, horns ; Hölle, hell ; König, king.
15. Land, land ; Berg, mountain ; Wild, game ; Kohle, coal ; Mund, mouth ; Bär, bear ; Getöse, noise, din ; Türke, Turk ; Laib, loaf ; Thau, dew ; Eis, ice ; neu, new ; Häuer, cutter, miner ; Aal, eel ; Speer, spear ; Boot, boat.
16. Stark, strong ; Obst, fruit ; Ast, branch ; Horst, eyrie, thicket ; Gestalt, figure.
17. Sprache, language ; Spritze, syringe ; spleißen, to split, to cleave.
18. Jagd, chase, hunting ; Jammer, lamentation ; bejahrt, aged.
19. Drache, dragon ; Fächer, fan ; Nachricht, intelligence, report, news ; Orchester, orchestra ; Chef, chief ; Chor, chorus, choir ; Chocolade, chocolate.
20. Fuchs, fox ; Ochs, ox ; Sachse, Saxon ; Mischung, mixture ; Wäsche, washing.

THE SOIL AND ITS CULTIVATION

Soils; their Constitution and Values. How to Understand Them. Their Fertility. Treatment of Bad Soil

By Professor JAMES LONG

IF it were possible to remove the surface and subsoil of a field perfectly, we should probably expose the rocks from which both have been produced. Both soil and subsoil are practically formed by the weathering and disintegration of the rocky surface of the earth. It is true that much cultivated soil owes its presence to glacial action or to the fact that it has been deposited by water, and this especially marks the fertile *alluvial* soils (soils which have collected by the action of running water), which are so frequently found in valleys and adjacent to rivers. The cultivated soil of to-day is, however, something more than pulverised rock. It contains *humus*—decomposed vegetable matter—which is largely the result of the work of man. The decayed roots of plants and farm manure all assist in the accumulation of humus, the value of which it is difficult to overestimate.

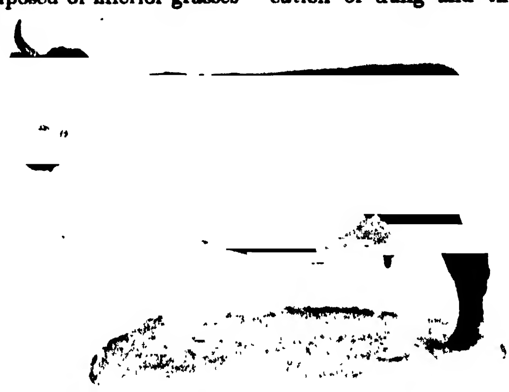
Depth of Soil. A soil may vary from 3 inches, especially on chalky downs, to 14 or even 15 inches in depth. Were it possible for the plough to do its work still further below the surface, the depth might be increased, and with great advantage. On many farms, however, the plough has never penetrated more than 10 ins., with the result that what is termed a hard "pan" is formed, through which plant roots penetrate and water percolates with difficulty. The decomposition of the subsoil, as of rock, depends upon the action of air, water, and heat. If we take a piece of hard tenacious clay or a lump of chalk, and expose it to the action of frost, we find after a thaw that it has been reduced to powder. Similarly, during summer, clay and other heavy soils laid up in ridges by the plough, dried by the sun, and wetted by rain, are so weathered that they break up, if not equally as fine, yet to the great benefit of the farmer. So it is in minor degree with the rock substances beneath; hence, the importance of deep cultivation, as of trenching or double digging in the garden, the surface soil being always kept at the top, and hence, too, the service rendered to man by the earth worms in constructing channels in all directions, and thus enabling air and water to find their way below.

The Perfect Soil. A perfect soil is one which consists of nearly equal quantities by volume of clay soil, sandy soil, chalky or calcareous soil, and vegetable soil rich in humus, and which is composed of finely divided particles. A good soil contains from 50 to 60 per cent. of sand; from 25 to 30 per cent. of clay; with pulverised limestone or chalk, and humus, each about 7 to 10 per cent.; sand, clay, and humus, usually represent about 90 per cent. of an average fertile soil. The soil contains both soluble and insoluble materials. The soluble portions are those of which plants make use in building up their structure; portions of the soluble matter are, however, commonly lost by drainage, and here we see the important part which is played by water, which is a large constituent of all soils, varying in quantity with their character, the climate, and the season. Plants are unable to utilise solid materials; the food they take up must be in solution. Water derives its power to dissolve soil substances, not only from the carbonic acid which is liberated in the soil by the decomposition of humus, but by that with which it is charged when falling in the form of rain.

Variations in Colour. Soils differ in colour owing to the presence of minerals, as *oxide of iron*, an oxide being a compound of oxygen and a substance which combines with it, and which imparts to it a red tint, while it differs in mechanical texture and character, owing to the fact that it is the product of different forms of rock, as limestone, granite, red sandstone, slate, or clay. Soil is termed heavy when it is chiefly composed of clay, and cold when the clay, more or less pure, comes close to the surface. A clay soil is a soil which contains over 50 per cent. of clay. A loam, which is regarded as a free, open, kind, and mellow soil, contains from 25 to 30 per cent. of clay, a clay loam coming between the two, and covering a clay subsoil; a sandy loam contains less than 25 per cent. of clay, and a sandy soil fit for cultivation less than 10 per cent. of clay. Soils over limestone or chalk with more than 20 per cent. of either are regarded as calcareous.

The four materials, clay, sand, limestone or chalk, and vegetable matter or humus, are essential to all soils. The clay provides tenacity and water-retaining power. The sand provides for the admission and percolation of water and air, as well as for free working and warmth. Limestone, or chalk, when pulverised, adds other important properties. It supplies a plant food, it neutralises acids, it attracts moisture, it improves the texture of the soil, and assists in the decomposition of materials which are intended as foods for plants, especially aiding, as we shall see later, in the process of *nitrification* (the chemical change resulting from the activity of soil organisms, of the nitrogen of humus into nitric acid). The vegetable matter of a soil assists in the retention of moisture. As it decomposes, it imparts warmth to the soil, and provides carbonic acid—which, as we have seen, enables water to dissolve certain necessary soil constituents—together with ammonia, which in its turn supplies plant life with nitrogen (the element forming $\frac{4}{5}$ths of the atmosphere).

How to Judge the Value of a Soil. The expert is usually able to value land from its colour, its texture, the depth of the surface soil, and the plants which grow upon it, from weeds to timber trees. If we select a field, and with a spade dig a few feet deep, we should not only be able to ascertain the approximate depth of the surface soil, but of the under, or subsoil, and possibly to reach the hard rock beneath. A good soil, from the farmer's point of view, is deep, of rich dark colour, such as brown or red, the pastures are thick, growing abundant clover, the woods and hedgerows strong and healthy, and the weeds, like the cultivated crops, vigorous and robust. Good land, too, should slope towards the south, and be well drained and provided with water for stock, but water should never lie on the surface. On the contrary, inferior land is that which is wet, with a thin or spongy surface soil, or which produces weak, poor crops, deficient clover in the pastures, and weeds and trees which indicate its second-rate character. Where pastures are largely composed of inferior grasses and such weeds as *couch*, or twitch (a grassy weed, *Triticum repens*), and especially where moss is prevalent, they may be regarded as either extremely poor in condition or naturally inferior. Bad land is also indicated by the presence of heather and bracken, rush and sedge, beech and fir; excessive water contributes to its sourness, and absence of humus to its poverty and physical insufficiency.



MR. M. J. SUTTON'S PRIZE DEXTER COW, IRISINE

Method of Comparison. The difference between a poor soil, especially one chiefly composed of sand, chalk, or gravel, and a rich soil, such as that of an old garden, may be readily ascertained in the following way. A given weight of each should be taken, carefully weighed, and dried until the weight remains constant, until, in fact, the whole of the moisture has been driven off. If now weighed, the loss sustained will represent the water contents. If we now burn the dry soil remaining with equal care, and again weigh the residue, the difference between the dry matter submitted to ignition and that remaining will represent the organic matter of the soil, practically consisting of humus. The unburnt ash represents the inorganic or mineral proportion.

We have seen that water plays an important part in the formation of soils and in the conveyance of soluble matter to the plant; it does something more; by its action upon the surface, especially where that surface is uneven, it removes or washes away the finer portions as, for example, during rain, and enables them to collect, as may be noticed on the lower side of a road, or in the furrows of an arable field. Some of the richest soils are those known as alluvial, which have been deposited practically as they are by water. We may take another example of a water-deposited soil from the warping of land in Lincolnshire. As the Humber rises, its water is flooded over land which has been selected for improvement, and allowed to remain at rest until it has deposited the fine particles of soil which it holds in suspension. In this way, by repeated floodings, a foot of *alluvium* may cover the surface, and thus immensely add to the value of the land and its crop-bearing character. Thus, water may not only contain matter in solution, but matter in suspension.

Fertility. In the practice of farming, matter essential to the growth and life of plants is removed in the crops which are harvested and carried away. This fertility is renewed in various ways; by the decay of the organic matter within the soil,—as animal manure, and the roots of plants; by the application of dung and the artificial or chemical fertilisers; by the ammonia brought down in the rain; by the weathering of the subsoil which follows deeper ploughing, stirring, or sub-soiling; and, where *leguminous* plants (plants of the order *Leguminosæ*) are grown, by the aid of the nitrogen which, under given conditions, they are able to extract from the atmosphere; and, lastly, as regards pasture land, by the aid of the droppings, both liquid and solid, of highly-fed animals. Fertility not only depends upon the presence of plant food in an available condition, but on sufficient moisture and on the bacteria (very minute organisms), which are essential to *nitrification*. These organisms, which require moisture, air, and heat—hence the greater rapidity of nitrification in summer—decompose organic matter, the nitrogen of which, being converted into nitric acid, unites with a base, such as *carbonate of lime* (a compound of carbonic acid and a base), and thus forms a combination of which the roots of plants can make use.

Again, the *bacteria* responsible for the collection of atmospheric nitrogen are essential, that this element may be supplied to the leguminous herbage, clover, beans, peas, and vetches, among others. Their presence is denoted by the tiny nodules which will be found on the roots of these plants.

How Plants are Fed. Only a small proportion of the food of plants, or of the materials of which they are composed, is obtained from the soil. In all, there are some 15 of the chemical

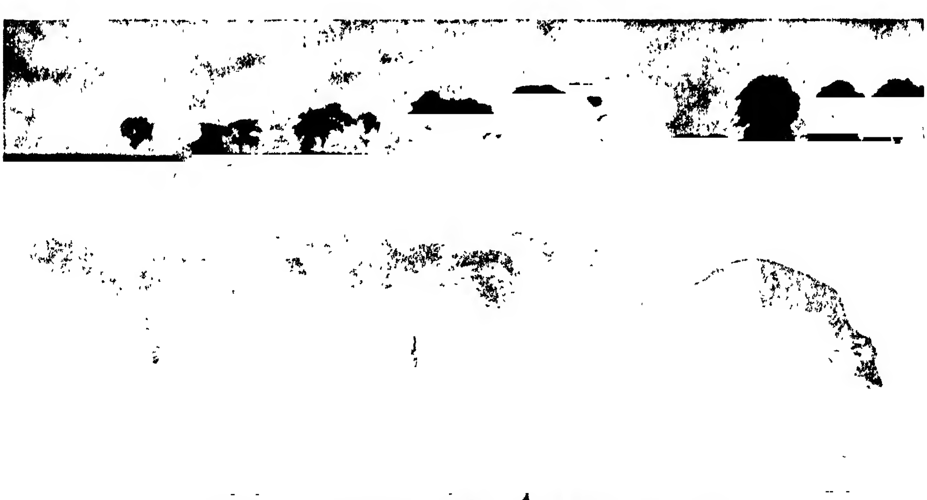
elements which are closely related to plant life. They include carbon, oxygen, nitrogen, hydrogen, and sulphur, all of which are combustible, and the minerals phosphorus, potassium, calcium, magnesium, sodium, and iron, all of which are essential. Of these the most important to the farmer are nitrogen, potassium, phosphorus, as phosphoric acid, and calcium (an alkaline earth metal), as lime, all of which it is necessary to supply with some frequency to old cultivated soils, as the supplies become exhausted, owing to the fact that they frequently run short, being utilised by plants more quickly than they are provided by Nature. That the materials named are present in plants can be proved by analysis, the mineral matter of soil being found in its ash after burning. The chief constituent of plant life is carbon, of which it is estimated that 3½ volumes exist in every 10,000, and that 28 tons, as carbonic acid, or carbon dioxide, are present in the air over every acre of land. Oxygen, which forms about one-fifth of the atmosphere, comes next in order, and of this it has been calculated that 21,000,000 lbs. are over every acre of land.

LINCOLN RAM: A CHAMPION AT THE ROYAL SHOW

Constituents of Soils. Brief reference may now be made to some of the chief materials found in soil. Clay is chiefly composed of silica and aluminium. It is seldom pure, but is tenacious, resisting the passage of water and of air; it is cold when wet, but liable to bake hard in summer. It has the property of retaining the most valuable constituents of both animal and artificial manure. Clay land is often termed season land, owing to the fact that it can only be cultivated under opportune conditions.

Sand is useless for crop-growing, owing to its want of tenacity, its inability to retain water, its destitution of organic matter and plant food, and its great warmth in summer. Just as clay needs sand and humus to improve its texture, so does sand need humus and clay to make it homogeneous, fertile, and able to retain water.

Effect of Lime on the Soil. A calcareous soil, whether over limestone or chalk calcium carbonate, is usually deficient in both organic matter and clay, while at the same time it may be excessively rich in carbonate of lime, which, when burnt, produces oxide of lime or quicklime, one of the most valuable aids to farming. Lime sweetens a sour soil by neutralising its acids; it assists in the retention of moisture, and in the improvement of texture. It enters into the composition of plants, and thus assists in the formation of the bones of animals; it further aids in the decom-



MR. W. R. FLOWER'S DORSET HORN SHEARLING EWES

position of organic matter, liberating nitrogen compounds, and by its action upon clay and other mineral constituents of the subsoil it provides a supply of potash.

How Soils are Improved. The improvement of soil is effected partly by Nature and partly by man. Improvement depends upon the addition of materials which provide food for plants, and which modify their texture as well as upon methods of cultivation, such as ploughing, cultivating, harrowing, rolling, and draining. In dry weather the surface of a field may be exceptionally dry, and even capped with a thin crust. This is chiefly owing to the evaporation of moisture. If this cap is broken by a sharp-toothed harrow or by the cultivator, water is induced to travel upwards from below, and to supply growing plants; hence the practice of stirring with the horse-hoe between the rows of roots, cabbage, or potatoes, or of harrowing a young plant of wheat in early spring. Where a *pan* exists, below which the plough has not penetrated, the upward movement of water is checked. Stirring often and deep is essential in good farming.

The movement of soil water is imperative in order that it may convey to plants the soluble materials of which they are in need. This movement is aided by artificial drainage where natural drainage does not exist; hence the importance of draining heavy clays and soils in which water is stagnant. Rain water adds nitrogen to soil, which, in the form of nitric acid and ammonia, it takes up in its passage through the atmosphere, but this important contribution of nature is of little avail, if, owing to want of drainage, a soil is impermeable, cold, and its water-table high, or, in other words, where water rests stagnant near the surface.

Restoring the Balance. Soils which contain an excess of one constituent, as clay, sand, gravel, peat, or chalk, are improved only by the addition of such materials, and by such a form of cultivation as will bring them approximately to the condition of loam. Long manure—*i.e.*, dung containing plenty of straw—sand, road scrapings, and chalk reduce the tenacity of clay, assist in making it pervious to air and water, raise its temperature, and make it less difficult to till. Sand and other light soils are improved by the addition of short manure—the produce of cows and pigs—by clay and by marl—a form of clay more or less rich in carbonate of lime. Such soils are thus made more homogeneous, compact, and tenacious; they hold water better, retain soluble plant food more perfectly, and are less liable to starve growing plants. A chalky soil, which is frequently thin, is equally improved by the addition of clay and heavy dung. One of the best methods, however, of increasing its fertility is that of growing turnips, sainfoin, and clover, by the aid of acid phosphatic manures, that they may be consumed by sheep which are folded upon them, and which are simultaneously supplied with rich foods such as cake and corn. Soils of a peaty character, which are usually sour, and sometimes a mass of spongy vegetable matter, are immensely improved by the aid of lime or chalk.

LEICESTER SHEARLING RAM

CHAMPION DARTMOOR RAM

Where peaty soils can be cultivated by the plough, liming or chalking may be followed by the employment of phosphates and potash salts, sown with vetches, clover, or some similarly suitable leguminous plant, with or without ryegrass, rye, or oats, and so prepared for potatoes and other suitable crops. There are, however, so many variations in soils of this character that the grower should observe what has been accomplished in the practice of his neighbours. The paring and burning of soil, whether with the object of destroying weeds or improving its texture, is not to be recommended. The nitrogen of a soil is principally found within nine inches of its surface; burning, therefore, is followed by a serious loss of this valuable constituent.

One of the most important methods of improving soils of extreme texture, such as clay or sand, is, as already mentioned, of ploughing-in green crops, such as mustard, rape, or vetches, to which the Germans add lupins with great success. These crops grown by the aid of potash salts and phosphate of lime, not only increase the percentage of humus or organic matter, but add nitrogen and carbonic acid.

To be continued

SHORTHAND

Second Instalment of the Special Course of Shorthand Taught by Sir Isaac Pitman & Sons on their Twentieth Century Plan

FOR the complete representation of words in shorthand there must be not only signs for the consonant sounds, as already explained, but also characters for the representation of the vowel sounds. The consonants form, as it were, the skeleton, while the vowels may be compared to the softer portions of the body. For example, the consonant characters represent merely two hard consonant sounds *chay, kay*, but if we add the soft vowel sound of long ē thus we get the shorthand representation of the word *check*.

Grammarians when dealing with the ordinary longhand alphabet inform us that "The vowels are *a, e, i, o, u*, and sometimes *w* and *y*." But these letters are quite inadequate for the indication of the twelve broad typical vowel sounds which are heard in the pronunciation of English words, and hence in Pitman's Shorthand four scales of signs, containing three each, are employed for the representation respectively of six long and six short vowel sounds. This method of dealing with the vowel sounds has a greater element of novelty than the consonant portion of the phonographic alphabet, but ability to detect the correct vowel sounds which are heard in any word will be gained after a little practice. It is absolutely necessary that the entire list of vowels should be thoroughly memorized.

Long Vowels. The six long vowels are as follow:

AH, EH, EE, AW, OH, OO,
as heard in the words
Alms, Ale, Eel, All, Oak, Ooze.

They should be pronounced as single sounds; thus, *ah* as in *alms* [not *a-aitch*]; *eh* as in *ape*; *ee* as in *eel*; *aw* as *awe* [not *a-double-you*]; *oh* as *owe*; *oo* as in *ooze*. They may be remembered by repeating the following sentence:

Pa may we all go too.
ah, eh, ee, aw, oh, oo.

The dots and dashes, representing the long vowels are numbered 1, 2, and 3, thus:

1. *ah* 1. *aw*
2. *eh* 2. *oh*
3. *ee* 3. *oo*

They are hence called *first-place, second-place,* and *third-place vowels* respectively.

There are three distinct positions at the side of each consonant where the respective vowel signs may be placed, namely, at the beginning, the middle, and the end. These places are also numbered 1, 2, and 3. They are counted from the point where the consonant begins. In the case of down-strokes, the vowel places count from the top downwards, thus

In the case of up-strokes, the vowel places count from the bottom upwards, thus

In the case of horizontal strokes from left to right, thus

The vowel signs are put in the places which correspond with their numbers; thus

tah (1), *teh* (2), *tea* (3), *taw* (1), *toe* (2), *too* (3);

lah (1), *lay* (2), *lee* (3), *law* (1), *low* (2), *loo* (3).

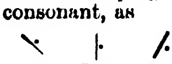
The vowel signs must be written at a little distance from the consonant. If allowed to touch (except in a few cases which will be mentioned hereafter), they would give rise to mistakes. A dash vowel may be written at any angle that is distinct, the right angle being generally most convenient; thus

or *two;* or *foe;* or *Joe.*

When a vowel is placed on the left-hand side of a perpendicular or sloping consonant, it is read *before* the consonant, as

ape, ate, age.

When a vowel is placed on the right-hand side of a perpendicular or sloping consonant, it is read *after* the consonant, as



pay, Tay, jay.

When a vowel is placed above a horizontal consonant, it is read *before* the consonant, as

ache, eke, own.

When a vowel is placed below a horizontal consonant it is read *after* the consonant, as

kay, key, no.

The best way to learn the vowels will be to repeat each one both before and after a consonant, in this manner:

aht ate eet awt oat oot tah teh tee taw toe too

and so on with the other consonants. In doing this the student will familiarise himself with the vowels that are strange to him, namely *ah*, *aw*, and *oo*, and discover the way to write a great number of words phonetically. For instance :

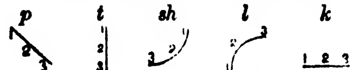
pooh, *ought*, *owed*, *dough*, *though*, *ooze*,

neigh, *knee*,

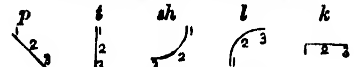
are written phonetically. In order to arrive at the correct vowel sound of any word the student must, until proficient, run over the scale of vowels till he has determined which is the one he requires.

The following diagrams further illustrate the positions of the vowels.

A VOWEL BEFORE A CONSONANT.



A VOWEL AFTER A CONSONANT.



In writing shorthand the student should strike the consonant first, and then fill in the vowel in the proper place.

Long vowels between two consonants. FIRST and SECOND-PLACE long vowels, when occurring between two consonants, are written *after the first stroke;* as

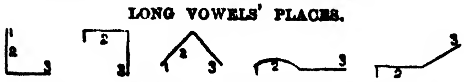
talk, *gate*.

But in order to avoid an awkward position for the sign, THIRD-PLACE vowels are written *before the second stroke;* as

team, *teach*, *read*.

The vowel is still in the third-place, as indicated in the following diagram :

LONG VOWELS' PLACES.



Short Vowels. In addition to the six long vowel sounds, there are six corresponding short vowel sounds in English, which are heard respectively in the words

păt, *pĕt*, *pĭt* ; *nŏt*, *nŭt*, *fŏŏt*.

The correspondence between long and short vowels is shown as under :

The short sound of *ah* in *palm* is *a* (say *ah* quickly) in *pat*.

The short sound of *eh* in *pate* is *e* (say *eh* quickly) in *pet*.

The short sound of *ee* in *peat* is *i* (say *ee* quickly) in *pit*.

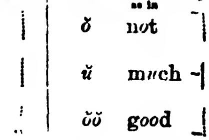
The short sound of *aw* in *nought* is *o* (say *aw* quickly) in *not*.

The short sound of *oh* in *note* is nearly *u* (*uh*) in *nut*.

The short sound of *oo* in *food* (say *oo* quickly) is *ŏŏ* in *foot*.

By *drawling* a word containing a short vowel, the corresponding long vowel will be heard. Compare *pick*, *peek* ; *cot*, *caught*.

Similar signs are employed for the short as for the long vowels, namely, dots and dashes; but the signs for the short vowels are written lightly, in order to indicate their short and lighter sound, thus :



Sound	as in	Sign	Sound	as in	Sign
ă	that		ŏ	not	
ĕ	pen		ŭ	much	
ĭ	is		ŏŏ	good	

The order of the short vowels may be remembered by saying the following sentence :

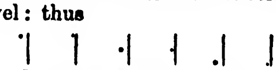
That pen is not much good.

The student will find the exact value of the short vowels by pronouncing each in conjunction with a following consonant. In order to gain familiarity with them, he should write them before the different consonants, and pronounce the combination, thus

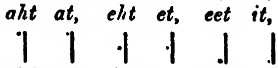
at *et* *it* *ot* *ut* *ŏŏt*

ad *ed* *id* *od* *ud* *ŏŏd*

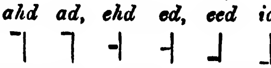
and so on with other consonants from *p* to *r* (down). When he has done this, he should contrast each short vowel with its corresponding long vowel : thus



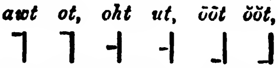
aht *at*, *eht* *et*, *eet* *it*,



ahd *ad*, *ehd* *ed*, *eed* *id*,



awt *ot*, *oht* *ut*, *ōōt* *ŏŏt*,



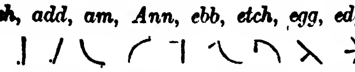
awd *od*, *ohd* *ud*, *ōōd* *ŏŏd*.

ahm *am*, *ehm* *em*, *eem* *im*,

awm *om*, *ohm* *um*, *ōōm* *ŏŏm*.

As a result of this practice, many common words will be made, of which the following are examples :

at, *ash*, *add*, *am*, *Ann*, *ebb*, *etch*, *egg*, *edge*, *ell*,



it, *itch*, *if*, *ill*, *odd*, *off*, *or*, *up*, *us*.

Short Vowels between two consonants. FIRST and THIRD-PLACE short vowels are written in the same position as their corresponding long vowels ; as

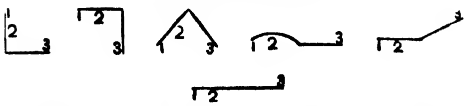
tack, tick, pap, pip, rock, rook.

SECOND-PLACE short vowels are written *before the second consonant;* as

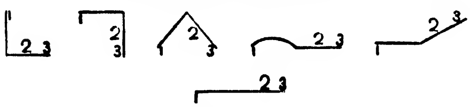
get, wreck, butt, tub, gull, lug.

Compare the places of second-place long and short vowels in the following diagrams and words:

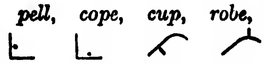
SECOND-PLACE LONG VOWELS AFTER THE FIRST CONSONANT.



SECOND-PLACE SHORT VOWELS BEFORE THE SECOND CONSONANT.



pale, pell, cope, cup, robe, rub,



take, Teck, roam, rum.

Diphthongs. There are four double vowels, or diphthongs, namely, ī, *ow, oi, ū,* as heard in the words *vie, vow, boy* and *due.* The first three are represented by a small acute angle, and the fourth by a small semicircle, thus

I OW OI U

The triphthong *wī*, as heard in *wife*, is represented by a small right angle, thus WI

The diphthong *oi* is written in the first-place, and therefore always at the beginning of a stroke, as

toy, coy, Roy.

The diphthong ū is written in the third-place, and therefore always at the end of a stroke, as

cue, your.

The diphthongs ī and *ow* and the triphthong *wī* may be written either in first, second, or third-place, as is most convenient, as

isle, tile, fowl, vowel, twibill.

Both ī and *wī* may be joined initially to a down-stroke, as

item, ivy, ice, ire; white, wife.

Both *ow* and *oi* may be joined initially to upward *l*, as

owl, oil.

Both *ow* and ū may be joined finally to a downstroke, as

bough, vow, pew, due.

After the consonant *n*, the diphthong *u* may be written thus, *new*, and *ow* thus, *now;* ī is joined to *n* thus, *nigh.*

Learners sometimes confuse the diphthong ī with the short vowel ĭ; also ū with the short vowel ŭ, and *ow* with the long vowel *oh.* The following pairs of words illustrate the contrast between diphthongs and vowels:

bite, bit; right, writ; tube, tub;
(noun) (verb)

use, us; rout wrote; sow, sow.

When a diphthong and vowel, or two vowels occur between two stroke consonants, each should, if convenient, be placed against the consonant to which it naturally belongs; thus,

newer, Louisa.

All the shorthand examples in this lesson should be carefully copied out.

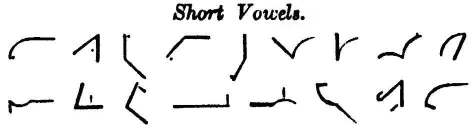
EXERCISE.

Write the shorthand form and place the longhand translation after it, as in the first line.

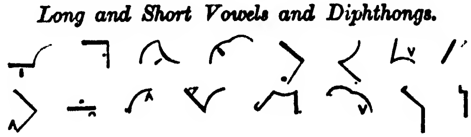
Long Vowels.

bah, saw, say, oat, ease, chew.

Short Vowels.



Long and Short Vowels and Diphthongs.



Write the shorthand word after the longhand in the following words.

The student is directed by a small capital letter when to write the letters L, R *and* H *downward.*

They, caw, awl, page, thief, HAWK, jeeR, folk, doom, dub, lad, yawL, bullock, mug, animal, mighty, loud, allow, HEW, wideR, envoy, Elijah, China, loyal, hope, value, Johnny, bunch, name, meadow, refuge, shook, notch, aRgue, attack, veal, shoRe, canaL, widow, gulf, farm, fury, tide, shaRe, naiL, HOY, manage, boy.

[A Key to the above exercise will appear in the next lesson.]

HOW TO USE SURVEYING INSTRUMENTS

Dealing with the Chain, Optical Square, Cross Staff Head, Box Sextant, Prismatic Compass, Vernier, and Transit Theodolite

By Professor HENRY ROBINSON

THE simplest form of survey is that carried out by means of the chain. The chain usually employed is "Gunter's" chain [1]. It is 66 feet long, divided into 100 equal parts which are called links, each link therefore is 7·92 inches long. Every ten links are indicated by brass tags. The centre, or 50 link, tag is circular in shape, and is generally larger and more conspicuous than the others. At ten links' distance from each side of the 50 link tag are tags with four teeth denoting 40 and 60 links (according to the direction of the chaining). Following these are three-teeth tags, denoting 30 and 70 links, and in their proper places tags carrying two teeth and one tooth, and marking 20 or 80 links, and 10 or 90 links respectively.

1. GUNTER'S CHAIN

The advantages of a 66 feet chain are that it bears the following relations to the standards of measurements in this country:

Statute Mile	=	1,760 yards = 5,280 feet.
,,	=	80 chains (of 66 feet).
,,	=	8 furlongs.
1 Square Mile	=	6400 square chains.
1 Acre	=	10 square chains.
,,	=	100,000 square links.
,,	=	4,840 square yards.
,,	=	4 roods (1,210 sq. yards each).
,,	=	160 perches.

The chain is thus a decimal part of an acre or mile, and this facilitates calculations.

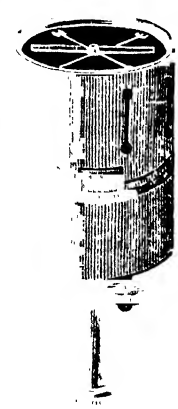
The usual accompaniments of a chain are 10 arrows (or pins) made of iron or steel, which are pointed at one end and have a ring at the other, to each of which is tied a piece of red cloth to make it clearly visible from a distance.

2. CROSS STAFF HEAD
Octagonal

Before surveying, the chain should always be tested, as it is liable to stretch with constant use.

Chaining a Line. In chaining a line (the direction of which is indicated by poles, or ranging rods), the man in front, who is usually called the leader, takes the ten arrows, and on being ranged in line by the man behind (or follower), he inserts one arrow into the ground and then proceeds for the next chain, the follower collecting these arrows as he goes on. The leader can greatly facilitate the speed of the chaining if he approximately takes up his position in the line by ranging himself by means of the previous arrow and the back pole. Some system of signals should be arranged between chainmen, that they may know in which direction to move. To prevent errors in long lines, it is usual at the end of the 10 chains (or after the whole of the arrows have been used) to cut a *station* in the ground. All the arrows are then taken by the leader. This means, that in the event of an error being made owing to the loss of a pin, or for any reason, it is only necessary to go back to the last 10 chain *station*, or *tally* as it is called.

The positions of any points to be surveyed are fixed by means of an offset staff, which is 10 links in length, each link being visible by difference of colour on the pole. The position is fixed by a right angle being set up (by the eye) from the chain line, and the distance to the point is measured with the offset staff. If there are two or more points to be taken on this offset, as, for instance, where two sides of a path are being measured, it is usual to enter the distances separately with a plus sign between them, thus: 30 + 15. In this case 30 shows the distance of the nearest point of the path from the chain line, and 15 is the width of the path. These offsets are limited as to distance on account of the inaccuracies that arise if a series of offset measurements are taken with the eye alone to preserve the continuity of the perpendicular. If offsets of any length are required, some form of instrument should be employed, as the *cross staff* or *optical square.*



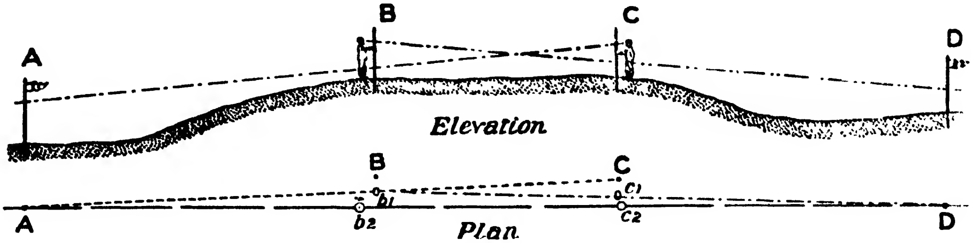
3. CROSS STAFF HEAD
Cylindrical

Cross Staff Heads. A simple form of the cross staff head can be made from a cylindrical piece of wood about four inches long and three inches in diameter, having two fine diametrical saw cuts at right angles to each other and about three inches deep. This is generally fixed to the top of an old ranging rod.

Fig. 2 shows an octagonal form of cross staff head. On

each of four rectangular sides of the octagon are plain sight slits, the remaining alternate sides having sight slits and rectangular slots with vertical hairs.

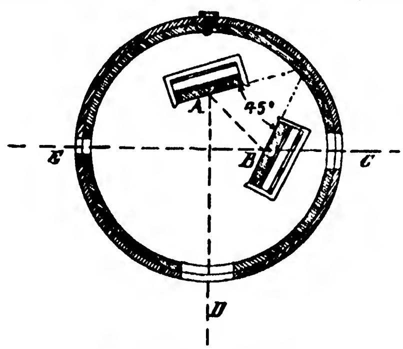
The adjustable cross staff [3] is another form of this instrument. It is more useful than those at B and C [5], so that they can respectively see the posts D and A. Operator C ranges B in line with A, making the line Cb_1A on the plan. Operator B then ranges C in line with D, making the line Bc_1D. This operation is repeated until all the four posts are



5. DOUBLE RANGING

just described, as it is possible to read angles, or take *bearings*, with it. It is cylindrical in form, divided into two parts, as shown by the illustration. The upper portion centring on the lower portion carries a vernier and a compass. The lower part has a grand circle divided into degrees. The vernier is revolved round the grand circle by the screw. The slotting for the upper portion is similar to that of the instrument described above, the lower portion having four slots diametrically opposite each other.

Optical Square. This is a small hand instrument used for setting out right angles. The optical construction is the same as that of the box sextant, only the mirror glasses A and B [4] are permanently fixed with their faces at an angle of 45° to each other, which gives a reflection of 90°. The sighting, or observation hole, E, is diametrically opposite the vision hole C. The glass B has the upper portion silvered (the lower being clear) to receive the reflection thrown by the mirror A. Sighting through the clear portion of the glass B along a chain line having the direction EBC, an object at right angles to the line of direct vision will be reflected by the mirror A on to the silvered portion of the glass B.



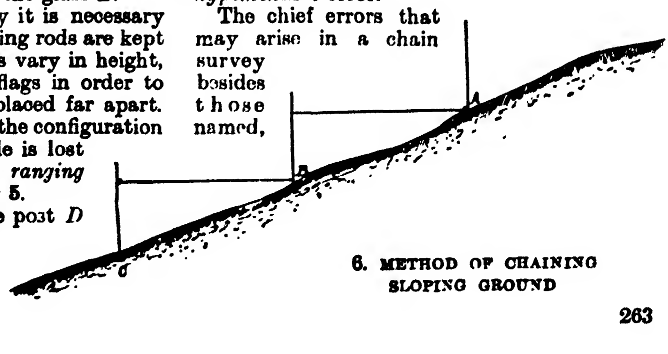
4. OPTICAL SQUARE

In ranging lines for a survey it is necessary to be very careful that the ranging rods are kept absolutely vertical. These rods vary in height, and should be mounted with flags in order to catch the eye when they are placed far apart. It often happens that, owing to the configuration of the ground, the forward pole is lost sight of. To meet this, *double ranging* has to be adopted, as shown by 5.

It being impossible to see the post D from A, owing to the rising ground intervening, two men take up intermediate positions in line, as shown by the line Ab_2c_2D on the plan.

At the ends of all survey lines, and at intermediate positions where other lines join, *stations* should be cut and a note of the chainage, etc., recorded on a piece of paper put in the hole. If the survey is to extend over any length of time, square-headed pegs should be driven into the ground, in order to enable the points to be picked up afterwards. When the ground is irregular, the chaining may frequently have to be done in short lengths, in order to get the true horizontal distance from point to point. This is usually done by bringing the point up to a ranging rod held truly vertical, and then by starting from the point thus found on the ground to the next point as illustrated by [6]. A being the first point, the handle of the chain is held there, and the first 50 links are measured off horizontally to B, and then plumbed to the ground (by dropping a stone or by a weighted cord) fixing point B. The remaining 50 links are measured off in the same way, and the point C fixed, and an arrow inserted there. The error which arises by measuring the sloping ground from A to C is what is termed *hypothenusal* error.

The chief errors that may arise in a chain survey besides those named,

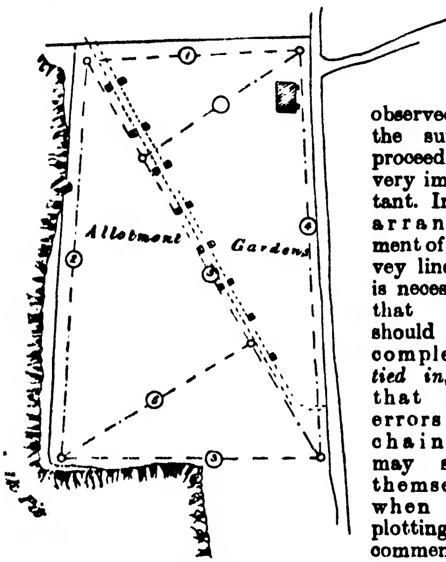


6. METHOD OF CHAINING SLOPING GROUND

and which have to be guarded against, are due:

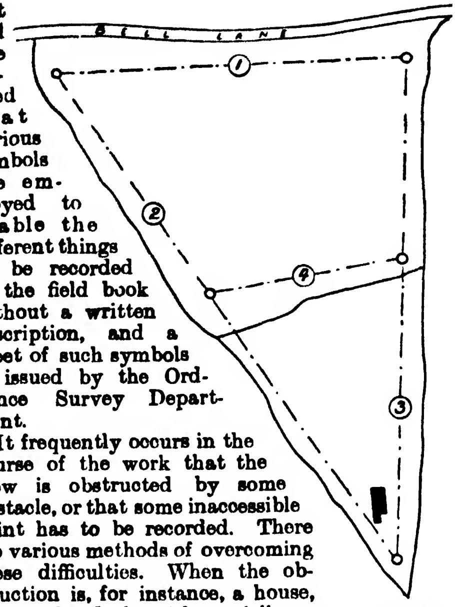
a. To the chain not being held tight.
b. To the handles not being held close against the arrows.
c. To the stretching of the chain by constant use.
d. To not keeping in proper alignment.

Considerable skill is required in determining the arrangement of lines for a survey best calculated to get the least number and yet to take in all the points satisfactorily. Also accurate notes are necessary, and sketches of all objects observed as the survey proceeds are very important. In the arrangement of survey lines it is necessary that they should be completely *tied in*, so that any errors in chaining may show themselves when the plotting is commenced, by the lines not properly joining. This can be illustrated by several sketches. The first [7] is that of a triangle which in itself is not complete, without the tie line, as shown. In the event of one of the lines being chained too short or too long, the only thing that would happen would be an alteration in the shape of the triangle, which, if the error were only slight, would not be noticeable. The tie line prevents this occurring. The second diagram [8] shows the arrangement of ties for a rectangular field, the position of the diagonal being chosen so as to act as a survey line to pick up the footpath. A more elaborate arrangement of lines is shown in 9. These tie lines are sometimes termed *chain angles*.



8. CHAIN SURVEY

For the purposes of plotting the survey, great care is required in keeping the field notes. The usual form of field book is shown in 10.

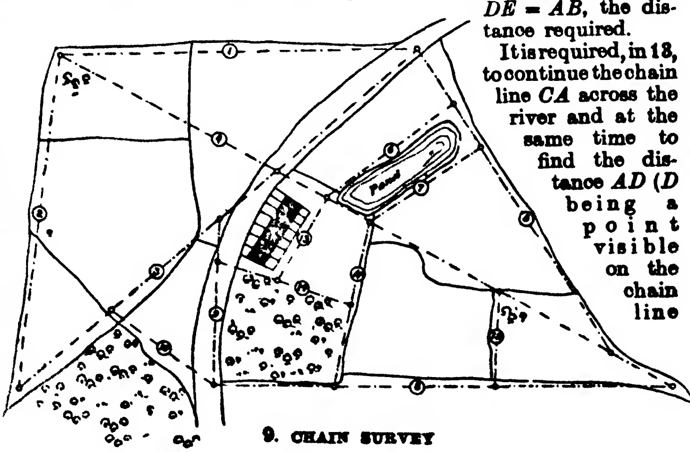


7. CHAIN SURVEY

It will be noticed that various symbols are employed to enable the different things to be recorded in the field book without a written description, and a sheet of such symbols is issued by the Ordnance Survey Department.

It frequently occurs in the course of the work that the view is obstructed by some obstacle, or that some inaccessible point has to be recorded. There are various methods of overcoming these difficulties. When the obstruction is, for instance, a house, it may be dealt with as follows. In 11 *Aa* is the chain line, which has to be continued towards *D*. Perpendiculars are set up at *A* and *a*, and equal distances, *AB* and *ab*, are measured to clear the obstacle. *Bb* is then ranged forward to *c* and *C*, and at these points similar perpendiculars are set up, the distances *cd* and *CD* measured, and made equal to *AB* and *ab*. *Dd* is therefore the direction of the chain line produced, and the length *bc* is the chainage of *ad* that could not be measured. The distance apart of the points *Aa* and *dD* should be sufficient to obtain a good range. Other methods are shown in 12 and 13. At *A* on the chain line *AA* in 12, a perpendicular *AC* is set up and is produced to *D*, making $AC = CD$. At *D* a perpendicular is set up and a straight line carried through *BC*, cutting it at *E*, making $DE = AB$, the distance required.

It is required, in 13, to continue the chain line *CA* across the river and at the same time to find the distance *AD* (*D* being a point visible on the chain line



9. CHAIN SURVEY

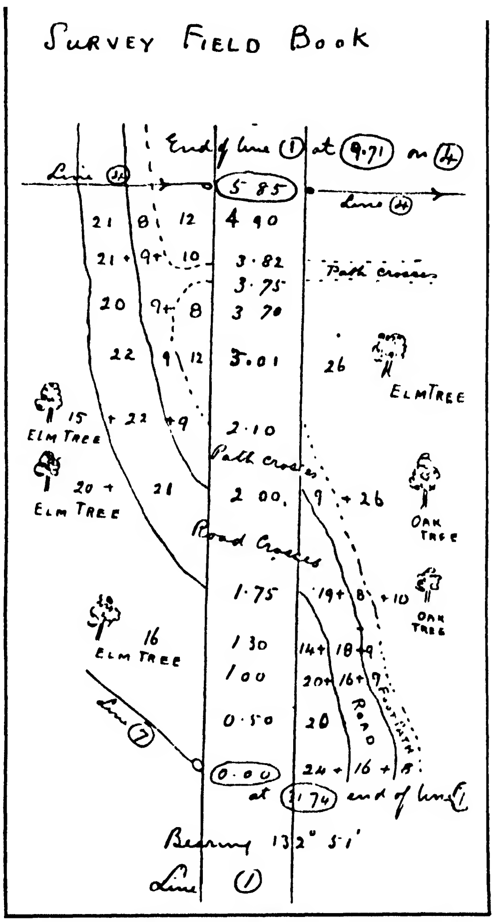
produced), and to clear the wood which obstructs the chainage. At A set up a perpendicular AB, and at B set up a perpendicular to BC, cutting the chain line produced at D.

$$\text{Then } CA : AB :: AB : AD$$

$$\therefore AD = \frac{AB^2}{AC.}$$

As it is possible to chain AB and AC, the distance AD can be calculated. If AB is made equal to $2AC$ the distance AD is $4AC$.

In the event of no instrument being available for setting up perpendiculars to a chain line, it can be accomplished by means of the chain alone. The proportions of the sides of a right-angled triangle may be as 3,4, and 5, or multiples of these numbers. It is required to set up a perpendicular to any point A [14] on a chain line. On each side of A measure off 30 links to B and C, and pin the chain handles down at these two points. If the centre brass tag of the chain be taken hold of and the chain pulled tight, a perpendicular can be ranged through the point D thus found. The triangle will, of course, have sides equal to 30, 40, and 50 links, and AD is perpendicular to the chain line BC.

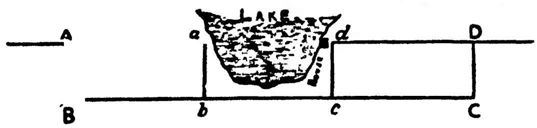


10. REDUCED FACSIMILE OF PAGE FROM A SURVEYOR'S NOTE-BOOK

It is necessary to be able to plot the position of the true north with regard to the lines of the survey. For extended surveys accurate methods must be adopted which will be explained hereafter, but for small surveys the following method suffices. At some convenient point on the survey we have a pole erected truly vertical, and with the pole as centre describe a circle round it. At any convenient time before noon mark the point at which the shadow of the pole thrown by the sun cuts the circle, and at the same number of hours after noon mark another point on the circle. The bisection of the angle formed by these two points and the pole give the north. In case the sun should be obscured at any time during the day, it is necessary to take several points at the right intervals before and after noon, so that there will be several chances of getting a result.

The most usual form of survey is by chaining the lines, and fixing their positions with regard to one another by angular measurements. In small surveys a combination of angular work and chainwork may be adopted. That is to say, the main lines may be checked by means of reading the angles between them, while the filling in of the minor details may be left to be done by the chain. In any case, the main lines are chained to get their lengths, and the tying of them together is done by reading with an instrument the angles they make with one another. In all work of this description the greatest care must be taken to place the instrument exactly over the point of intersection of the lines between which the angle is intended to be taken; also that in reading the angles the telescope of the instrument be first directed to the left-hand object, in order that the angle may be read from zero onwards, as the graduations of the instrument are from left to right. The instruments generally employed are the *Theodolite*, *Box Sextant* and *Prismatic Compass*, which are described in their proper place. The theodolite is the one chiefly used, the smaller instruments being employed in detail work, or for work involving less accuracy. In this part of the subject, dealing with small theodolite surveys, the lines are all chained in the ordinary way. For work of greater magnitude the lengths of the lines are calculated, as explained later. It is never advisable to trust to one reading of an angle, but it is usual to *repeat* the angle as follows. After the first angle has been taken and the plates clamped the instrument is again turned on the first point, but with this difference, that instead of starting with zero on the first point, the telescope (with the angle just observed on the plate) is sighted on to the point, so that the

second reading should be the sum of the two angles. This should be repeated a third time, and the sum of the differences of the three angles thus obtained, divided by three, will give the mean angle. An illustration of this is as follows:

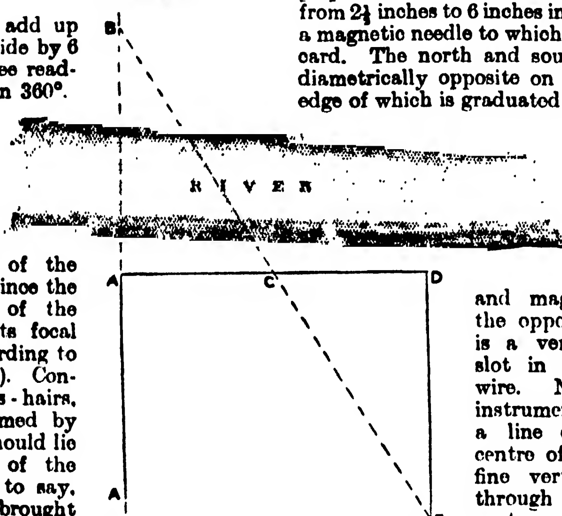


11. OBSTRUCTION TO CHAIN LINE

	ANGLE.	DIFFERENCE.
1st reading	175° 30′	175° 30′
2nd „	351° 0′	175° 30′
3rd „	166° 30′	175° 30′
	3)	526° 30′
	Mean =	175° 30′

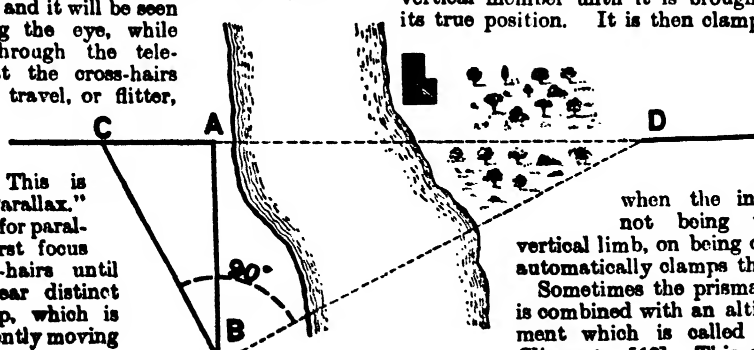
It is incorrect to add up the readings and divide by 6 unless the whole three readings come to less than 360°.

Parallax. The eyepiece of the telescope of any instrument, such as the theodolite, serves to give a distinct and magnified view of the image. Therefore, since the magnifying power of the eye-piece is large, its focal range is small (according to its magnifying power). Consequently the cross-hairs, and the image formed by the objective lens, should lie in the focal plane of the instrument, that is to say, the image must be brought on to the cross-hairs. The plane of the cross-hairs is fixed, while that of the image moves backwards and forwards, according to the movement of the objective lens (as when focussing). Therefore, the coincidence of the image and cross-hairs in the focal plane is imperfect, and it will be seen by moving the eye, while looking through the telescope, that the cross-hairs appear to travel, or flitter, over the surface of the image. This is called "Parallax." To adjust for parallax we first focus the cross-hairs until they appear distinct and sharp, which is done by gently moving the eye-piece in or out. The objective lens is then moved until the image comes into perfect focus. These operations are repeated until there is no perceptible movement of the cross-hairs. When once the adjustment for parallax has been made for the day, no further attention is required so long as the same person uses the instrument, but another individual with a different focal range would have to carry out adjustments to suit his vision. It should be remembered that adjustment for parallax should be made previous to that for Collimation, which is explained elsewhere.



12. CHAIN LINE OBSTRUCTED BY RIVER: METHOD OF CROSSING

Prismatic Compass. This instrument [15] consists of a circular metal box, varying from 2½ inches to 6 inches in diameter, containing a magnetic needle to which is attached a circular card. The north and south of the needle are diametrically opposite on the card, the rim or edge of which is graduated into degrees and half degrees. The north of the needle is fixed at 180°, the south at 360°, or zero. The box is fitted on one side with a combined sighting slot (*s*) and magnifying prism. On the opposite side of the box is a vertical limb, with a slot in it, carrying a fine wire. Now, assuming the instrument is resting at zero, a line drawn through the centre of the slot (*s*) to the fine vertical wire will pass through the card at 360°, its centre, and 180°. In taking a reading we sight through the slot, and bring the fine wire on to the distant object, the "bearing" of which has to be determined. The card will sway a little, but this can be checked by a finger clamp at the base of the vertical member until it is brought to rest in its true position. It is then clamped, and the reading taken. The prism and vertical limb can be shut down when the instrument is not being used. The vertical limb, on being closed down, automatically clamps the needle.

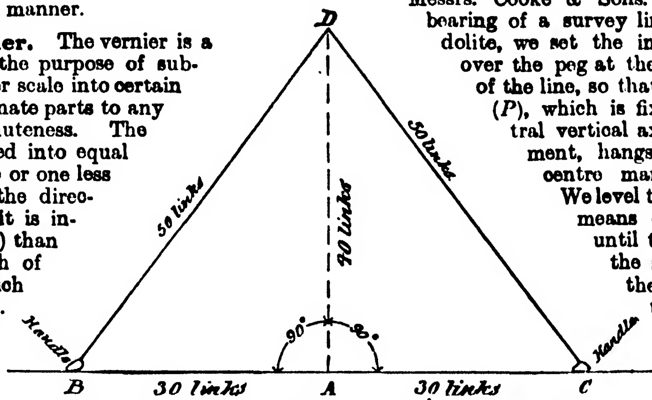


13. CHAIN LINE OBSTRUCTED BY RIVER: METHOD OF CROSSING

Sometimes the prismatic compass is combined with an altitude instrument which is called a *Prismatic Clinometer* [16]. This consists of a prismatic compass (as previously explained) and a circular box con-

taining a loaded and graduated card. The instrument stands on a base. By looking through the slot, as depicted by the illustration, and tilting the instrument on its base till the alignment of the slot, hair, and the object is correct, the degrees of inclination can be read in the ordinary manner.

The Vernier. The vernier is a scale made for the purpose of subdividing another scale into certain equal proportionate parts to any degree of minuteness. The vernier is divided into equal parts, one more or one less (according to the direction in which it is intended to read) than an equal length of the scale to which it is to work. Fig. 17 depicts a scale (A), divided into degrees, which are subdivided into half degrees. The length of the vernier for this scale is taken to equal 29 of the subdivisions or half degrees. This length is equally divided into 30 parts. Each part will, therefore, be $\frac{1}{30}$th (or one minute) less than a half degree subdivision. From this it will be seen that if the vernier arrow is moved forward one minute on the great scale it will be recorded on the vernier scale. Figure 17 shows a vernier indicating an equal number of degrees on a great scale (A), while 18 shows a vernier indicating a reading of 23° 12′ on the great scale (B).



14. SETTING UP A PERPENDICULAR WITH THE CHAIN

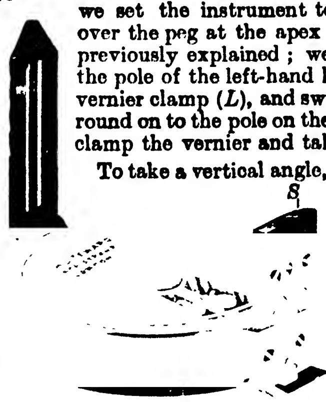
Box Sextant. The box sextant is a hand instrument [19] for measuring angles up to 130°. It consists of a circular metal box (about 3½ inches in diameter) containing two glasses, one movable and the other fixed. The fixed glass is silvered on the upper half, the lower being clear, while the movable or reflecting glass is silvered all over. The thumbscrew D operates the movable mirror. The angle between the object observed by the eye and the reflected object is recorded by the vernier on the index arm which works along the grand circle. The method of obtaining the angle between two objects is as follows: Sight (by means of the telescope T) through the clear portion of glass on to the left-hand object; operate the screw D until the right-hand object appears (by reflection) on the upper or silvered portion of the fixed glass. When the reflected and the observed object coincide, the reading may be taken, and the value of the angle obtained. In order to facilitate the reading of the vernier a magnifying glass is provided.

In cases where the objects are not far apart the telescope is dispensed with and drawn out, the opening in which it rested being covered by a slide with a small hole in its centre. Looking through this hole serves the same purpose as looking through the telescope.

The Transit Theodolite. This instrument [20] is explained by one made by Messrs. Cooke & Sons. To take the bearing of a survey line with a theodolite, we set the instrument firmly over the peg at the commencement of the line, so that the plumb-bob (P), which is fixed to the central vertical axis of the instrument, hangs truly over the centre mark on the peg. We level the instrument by means of the screws (s) until the air bubble in the spirit level is in the centre. Having the instrument level, we clamp the vernier (A) to zero on the graduated circle (B) by means of the clamping screw (L). The final adjustment of the vernier is made by the tangent screw (T). Now release the clamp (K), which will enable the whole instrument to be revolved (without altering the zero), and set it up by the compass needle attached to the instrument to magnetic north. The final adjustment is made by the tangent screw t_1. The instrument being now at zero and pointing to the magnetic north, release the vernier and swing the telescope round from left to right until it rests on the pole on the end of the line. Carefully adjust the telescope by the tangent screw (T) until the cross-hairs in the instrument cut the centre line of the pole. The bearing can now be read by the vernier, and will be a *forward bearing.* This operation is repeated with the instrument set up at the other end of the line and the telescope turned on to the first pole. The reading obtained will be a *backward bearing;* the difference between the two should be 180°, which is a check on the work.

To take a horizontal angle with the theodolite we set the instrument to zero and place it over the peg at the apex of the two lines as previously explained; we then turn it on to the pole of the left-hand line. Releasing the vernier clamp (L), and swinging the telescope round on to the pole on the right-hand line, we clamp the vernier and take the reading.

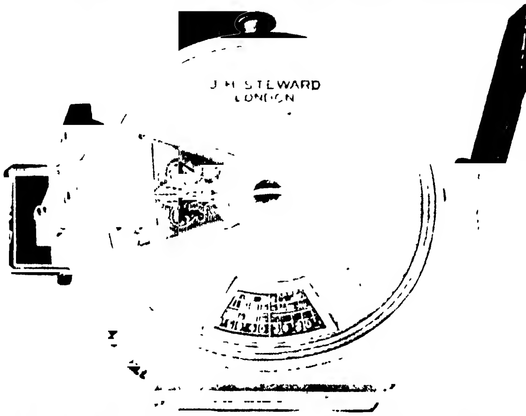
To take a vertical angle, set the vernier (V) (on the vertical graduated circle D) to zero, depress the telescope for a negative angle, and raise it for a positive angle, obtaining the value by means of the vernier.



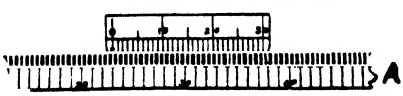
15. PRISMATIC COMPASS

The vertical motion of the telescope is governed by the clamping screw (H) and the tangent screw i_4.

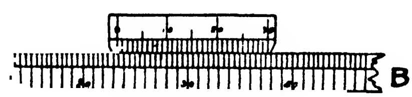
Theodolite Adjustments. In adjusting the levels on the horizontal plate perpendicular to the vertical axis of the instrument we set up the instrument firmly on good solid ground, release the lower clamping screw and turn the head until the longer of the two levels lies in a direction parallel to an imaginary line joining the centres of two of the foot-screws. The shorter tube then lies towards the third. Now level the instrument by means of the foot-screws, so that both bubbles lie in the middle of their runs. Then turn the head of the instrument one half round in azimuth, that is to say, through an angle of 180 degrees. If the bubbles remains true they are in perfect adjustment, but if not, then by means of the capstan-headed lock-nuts (c, c), by which the larger one is attached to the horizontal plate, correct it for half the error only, and for the other half by means of the foot-screws.



16. PRISMATIC COMPASS AND ALTITUDE INSTRUMENT



17. THE VERNIER



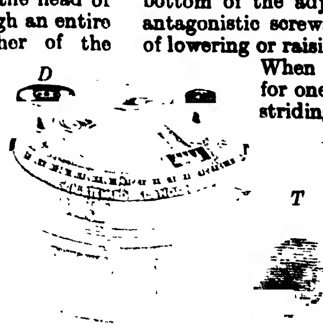
18. THE VERNIER

Now complete the revolution of the head, bringing it to its first position, and again notice this bubble. If it is not quite exact, the same operation must be repeated, that is to say, half the error must be again eliminated by means of the capstan-headed nuts, and the other half by means of the foot-screws. By repeated trials this level can thus be eventually exactly corrected, after which the smaller bubble may be compared with and adjusted by it, and when the head of the instrument can be twisted through an entire revolution without disturbing either of the bubbles from their positions in the middle of their runs, the levels are in perfect adjustment.

The same adjustment can be made by reference to the level which is mounted on the vernier arms of the vertical circle, sometimes called the azimuth level. This bubble is of more delicate construction than those on the horizontal plate, so that by its use greater accuracy may be attained. It must first be carefully corrected, so that the head of the instrument may be turned in azimuth through an entire revolution without disturbing the position of the bubble, after which the levels situated on the horizontal plate can be compared with and adjusted by it. The operation is, however, of somewhat longer duration, and as the method given above will be found sufficiently accurate for all practical purposes, no further description of it is given here.

Transit Axis Adjustment. The adjustment of the transit axis so as to be truly horizontal is effected by means of the antagonistic screws (a, a) situated just below one of the Y bearings, and can be carried out with the aid of a striding level. It is an adjustment that is not likely to require much attention, for having once been carefully corrected by the maker of the instrument nothing but very rough usage can possibly displace it again.

Having levelled the instrument carefully by means of the bubbles on the horizontal plate, and noticed that this adjustment is perfect, turn back the caps which cover the ends of the transit axis in its bearings. Now erect the striding level on the top of the axis just over the bearings, and observe it carefully. (Reverse it, in order to examine its own adjustment, and if any error be discovered, this must be corrected before proceeding further.) If the bubble does not remain in the middle of its run, it must be made to do so by slightly opening or closing the slit in the bottom of the adjustable Y, by means of the antagonistic screws (a, a), which has the effect of lowering or raising the end of the transit axis. When the adjustment is completed for one position, the bubble in the striding level ought to remain steady while the head is twisted in azimuth through an entire revolution.



19. BOX SEXTANT

This same adjustment may be accomplished without the aid of a striding level in the following manner: Set up the instrument at about forty or fifty feet distance from

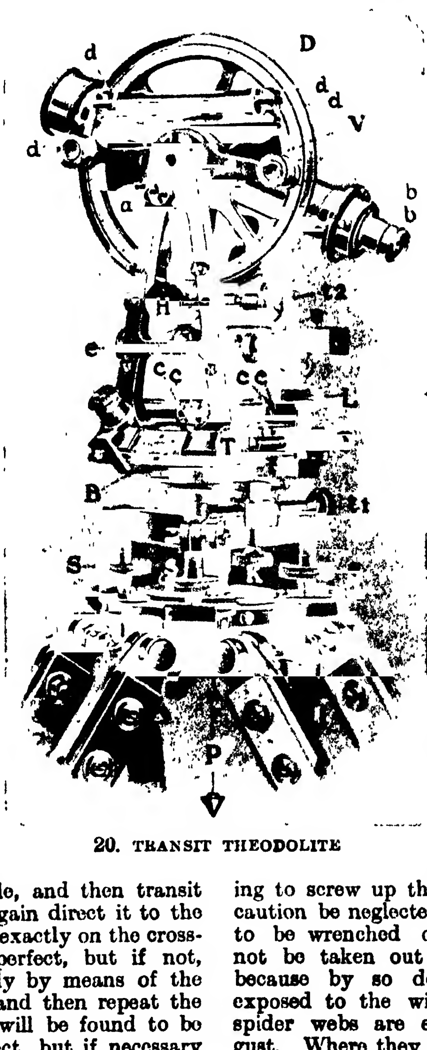
a high wall or other object of considerable elevation, level it carefully, and direct the telescope to some small point situated as high up as possible, and bring the cross lines to bear exactly upon it. All parallax (as previously explained) must now be carefully eliminated. Tilt the telescope and make a small mark on the wall near to the foot, at the point of intersection of the cross lines. Now turn the telescope 180 degrees in azimuth, transit it, and again direct it to the upper mark, after which tilt it as before and see if the point of intersection of the cross lines exactly corresponds with the lower mark. If it does so the transit axis is truly horizontal, but if not, half the error must be corrected by means of the antagonistic screws (*a*, *a*) as previously described, and the operation repeated in order to ensure accuracy.

Horizontal Collimation. The adjustment of the central line of vision of the telescope perpendicular to the transit axis, in other words, *horizontal collimation*, is effected by means of the pair of antagonistic screws (*b*, *b*) situated near the eye end of the telescope.

Having carefully levelled the instrument, direct the telescope to some small object, such as a pin-hole in a piece of white paper, fixed at as great a distance as can be distinctly seen, and by means of the lower tangent screw bring the centre of the webs to fall exactly upon it, all clamps being firm. Now having turned back the covers of the bearings and loosened one of the clipping screws (*e*, *e*) at the lower extremity of the vernier arm, gently lift the upper part of the instrument and reverse the transit axis in its bearings. Release the clamp to the vertical circle, and then transit the telescope, after which again direct it to the previous object. If it falls exactly on the cross-hairs the adjustment is perfect, but if not, correct half the error only by means of the antagonistic screws (*b*, *b*) and then repeat the operation. This time it will be found to be almost, if not quite, correct, but if necessary again divide the error by means of the screws, and so on until the adjustment is perfect. No adjustment is provided or required for vertical collimation with this instrument.

To adjust the level attached to the vernier arms of the vertical circle, so that when the central line of vision of the telescope is horizontal, and the zero lines of the vertical verniers coincide with the zero diameter of the vertical circle, the bubble may be in the middle of its run, we manipulate the capstan-headed lock-nuts (*d*, *d*) that attach the level bubble to the vernier arms.

Having levelled the instrument carefully by means of the bubbles on the horizontal plate, bring the bubble in the azimuth level to the middle of its run by means of the antagonistic screws (*e*, *c*) at the end of the clipping arm. Now set the zero diameter of the vertical circle to coincide exactly with the zero lines on the vertical verniers, and clamp it there. Observe an ordinary levelling staff held at as great a distance as it can be distinctly seen, and take the reading by the horizontal web. Now release the clamp and transit the telescope, and again adjust the zero diameter of the vertical circle to the zero lines on the verniers. Revolve the head in azimuth one half turn, bringing the telescope to its former position, and once more take the reading of the staff. If it is not the same as previously observed, correct half the error by the antagonistic screws at the end of the clipping arm and then repeat the operation until all error is by this means eliminated. When the adjustment is complete correct the azimuth level by means of the capstan-headed lock-nuts, so that the bubble remains in the middle of its run.



20. TRANSIT THEODOLITE

The adjustments referred to above must be carried out with the greatest care in order to avoid damaging the instrument. For example, in operating the capstan-headed nuts, care must be taken to unscrew one before attempting to screw up the other. Should this precaution be neglected, the screw heads are apt to be wrenched off. The eye-piece should not be taken out of its tube in the field, because by so doing the cross hairs are exposed to the wind, and if constructed of spider webs are easily broken by a sudden gust. Where they are constructed of platinum wire, or are marked on glass, these precautions are unnecessary.

After the instrument has been used in the field, and before being placed in its box, it should be carefully wiped over with a duster slightly oiled.

To be continued

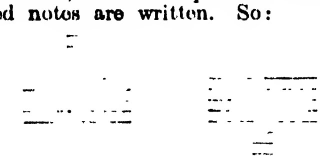
THE WHOLE LANGUAGE OF MUSIC

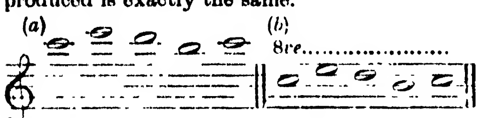
Illustrated Interpretations of the Terms and Phrases employed, with Explanations of Scales, Modes, and Key-signatures.

By J. CUTHBERT HADDEN

WE return now for a little to the Stave. If we were to fill up the whole of our Great Stave of 11 lines and 10 spaces, we should still leave unexpressed a very large number of musical sounds. Count, for instance, the keys of a piano: there are 85 notes in the compass of seven octaves. Even human voices take us beyond the limits of the Great Stave. How, then, are the extreme sounds, high or low, shown in musical notation? They are expressed on what might be called a borrowed stave, borrowed just as it is required. Little lines are added temporarily, and on these, or in the spaces so created, the required notes are written. So:



These additions are called technically *Leger lines*, "leger" being simply the French word for "light." There is no limit to the addition of leger lines, though for convenience, and not too greatly to distract the eye, a series of notes which would run much above or much below the stave is often written an octave higher or lower than the pitch required, and the direction added to render the passage an octave lower or higher as the case may be. Thus (*b*) is less troublesome to write than (*a*), and the effect produced is exactly the same.



The term *octave* ought perhaps to be explained here. As only seven letters are used in naming the lines and spaces of the stave, it is obvious that when one set of seven is exhausted we must begin with another. The name-letter with which we begin the second series will of course be the eighth of the first series, and it is from this circumstance that the term octave (or eighth) is derived. The arrangement that any sound and its octave shall bear the same name is, as Dr. W. H. Cummings observes, in accordance with nature, for we find that, although there is a difference in pitch or height, yet the two sounds (test it on the piano) so accord together that they seem to be almost like one sound.

In the writing of music much space is saved by the use of abbreviations, signs for repeats, for "embellishments," for manner of performance, and the like. We will take the *Repeats* first. These are indicated in various ways. If the composer wants the performer to repeat from the beginning he employs the term *Da Capo* or its abbreviation *D.C.* In that case the repetition continues until the term *Fine* occurs, or a *Pause* mark (𝄐) is seen over a double bar. Another way of indicating a repeat is founded on various uses of the Italian word *Dal Segno* (from the sign). The "sign" may be in the form of an 𝄋 or the initial letters *D.S.*; in any case the repeat will be made from the sign, whatever it is. A third method employs dots before or after a double bar. Thus:

Here the first illustration indicates a repetition of the preceding movement; the second a repetition of the following movement. If a short passage—say two or three bars—is to be repeated, the term *Bis* (twice) is written over the stave. Very often an alteration has to be made of the close of a repeated portion, in which case the indication is—

Many other space-saving devices are met with, most of which are best explained to the eye, as here:

The latter example is termed an *Arpeggio*, and means literally after the manner of the harp,

where the notes of a chord are played quickly one after another.

As regards manner of performance, the *Slur* and the two kinds of *Staccato* marks are the most frequently used of what may be called non-notational abbreviations. The slur is a curved line drawn over or under a group of notes to indicate that they are to be performed in a smooth, connected manner, or, in the case of a setting of words, that the notes so marked are to be sung to one word or syllable:

The term *Legato* also indicates a smooth style of performance, but is generally used as a direction for long passages. The slur, unfortunately, is made to do double duty, for it is employed also as a *tie* or *bind* between two notes on the same degree of the stave when the second note is to be joined to the first. When notes are to be sung or played in a crisp, short, disconnected manner, dots and dashes called *Staccato* marks are introduced—a dot when the note is to be robbed of a very slight portion of its legitimate time; a dash when the effect is to be still shorter.

Among abbreviations which are not strictly notational must also be noticed the marks < and >, which signify, the first a *Crescendo* (generally written *Cres.*), increasing in loudness: the second a *Decrescendo* (*Decres.*), decreasing in loudness. The terms themselves and the signs are used indiscriminately. Again, there is the mark of emphasis, indicated either by > or ∧ placed over the note or chord to be affected. A very strong emphasis is expressed by *sf* or *sfz*, standing for *sforzato* (forced); while a reinforcement of tone is indicated by *rf* or *rinf* (*rinforzando*). The most frequently used of all abbreviated directions affecting the intensity or strength of sound are, however, the following:

f, *forte*, loud.
ff, very loud.
fff, as loud as possible.
mf, *mezzo-forte*, moderately loud.
mp, *mezzo-piano*, moderately soft.
p, *piano*, soft.
pp, very soft.
ppp, as soft as possible.
fp, loud, then soft.

The subject of embellishments would require a volume to itself; and indeed the student who desires to master all its details must be left to consult Mr. Dannreuther's "Primer of Ornamentation" where the theme is treated exhaustively. Here we can notice only the most common forms of ornamentation. First comes the *Shake*, an ornament produced by the rapid alternation of two consecutive notes (*a*). The Italian word for shake is "trillo," and the sign for this embellishment is simply a contraction of "trillo"—*tr*. When the shake is to be prolonged through several bars, as at the close of Mendelssohn's Wedding March, a waved line after the *tr* indicates how far the ornament is to continue.

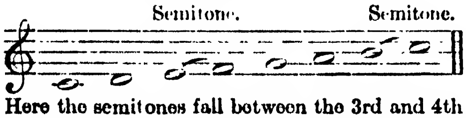
The shake frequently, though not always, ends with a *Turn*, another ornament representing a group of five notes. It exists in two forms, the direct and the indirect. The sign for the direct turn is ∼; for the indirect turn ≀. The direct turn begins with the note above the one written (*b*); the indirect with the note below (*c*). A sharp or flat accompanying the sign of the turn shows that the note above or below the written note is to be sharpened or flattened (*d*).

The shake and the turn are thus expressed by signs: other embellishments are expressed by small notes. The one most frequently met with in older music is the *Appoggiatura*. The term comes from the Italian "appoggiare," to lean upon; and this is an ornament which "leans upon" a principal or accented note. It takes half the length of the note which follows it, except when the principal note is dotted, when it takes two-thirds (*e*). In modern music it is more usual to write the appoggiatura in the text as a full-sized note with its proper value. The older composers never did this, and it is necessary to understand exactly what they meant when they wrote the small note.

The *acciaccatura* is the only other small note ornament that need be noticed. It is generally marked with an oblique line through the head of the note, and is always to be sounded as a very short note, proceeding immediately to the principal note (*f*).

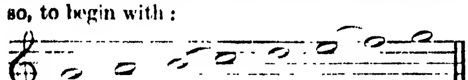
We now take up the subject of scales and modes. "Scale" is one of the most familiar terms in music. The word comes from the Latin *scala*, a ladder.

And a ladder the scale, in fact, is: a series of notes having a gradual and regular ascent or descent, by tones and semitones, from any given note to its octave. In modern music two scales only are recognised—the diatonic and the chromatic. The term diatonic, derived from Greek words meaning "through a tone," sufficiently indicates the nature of the scale to which it is applied, this scale consisting chiefly of tones—that is to say, whole tones. Set down in notation, taking the major diatonic scale of C as a model, it appears thus:

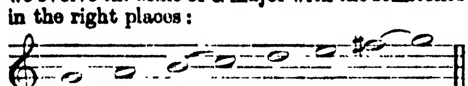


Here the semitones fall between the 3rd and 4th and 7th and 8th degrees, all the other intervals being distant a whole tone from each other.

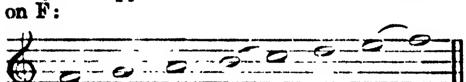
This scale of C is often called the "natural" scale, because it is written without sharps or flats, and because it can be played entirely on the white keys of a piano. It is, at any rate, the type or model upon which all other major scales are formed. Every major scale, beginning on whatsoever note, must, like this "natural" scale, have its semitones between the 3rd and 4th and 7th and 8th degrees, with full tones between the remaining degrees. Let us see, then, how other scales are constructed on this pattern. Say we want to rear a scale on the note G. We write it so, to begin with:



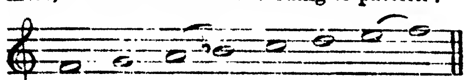
But we see at once that something is wrong, for the second semitone is between the 6th and 7th degrees when it ought to be between the 7th and 8th. Obviously, to correct this we must raise the pitch of F by placing a sharp before it, so as to make it a whole tone higher than E and consequently a semitone lower than G. Thus we evolve the scale of G major with the semitones in the right places:



Again, suppose we desire to commence a scale on F:



Here it is the first semitone that is misplaced: instead of being between the 3rd and 4th, it is between the 4th and 5th degrees. To correct that error it is necessary to lower the fourth note B by placing a flat before it. Then, once more, we have our scale according to pattern:

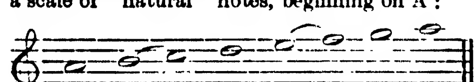


The same procedure applies in the case of major scales formed on other notes. A scale on D will require two sharps to set the semitones in order; a scale on E flat, three flats; a scale on E, four sharps, and so on.

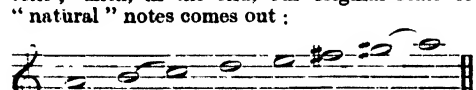
It would be very inconvenient to have to write these sharps or flats every time the notes requiring them appeared; hence they are written, once for all, at the beginning, just after the Clef sign. Arranged in this way they are termed the *Key-signature*. They are always placed in the order in which their use has been called for: in the case of the sharps, F, C, G, D, A, E, and B sharps; in the case of the flats, B, E, A, D, G, C, and F flats. The student must learn to tell at once what key any given signature represents. With that object in view we set down here a complete table of all possible signatures;

Let it be added that the keys of C♯ and C♭ are very seldom used, being (on keyboard instruments at least) identical with D♭ and B, which are much more easily written.

Having thus disposed of the major diatonic scale, we must now consider its relative, the minor scale. Here again it is a question of the order of the tones and the semitones. The major scale is so called because the interval of the third from its first note is major, that is, two whole tones and a half tone. The minor scale, on the other hand—hence its name—has only a tone and a semitone between its first and third notes. We will make an experiment and write a scale of "natural" notes, beginning on A:



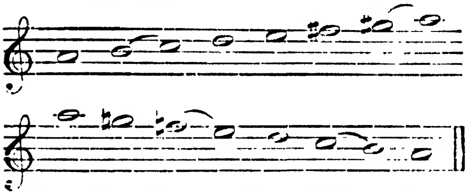
Here the distance from A to C is a tone and a half, a minor third; and that is what determines the scale. It is a minor scale. It can be sung or played with satisfaction to the ear as far as the seventh note. Then the ear—the modern ear—long accustomed to the ascent by a semitone from the seventh to the keynote in major keys, seems to demand a similar progression in the minor, so that we are obliged to alter the G to G♯. Unfortunately, this creates an awkward gap of an augmented second—a tone and a half—between F and G♯; therefore, to make a smoother melodic progression, the sixth note of the ascending minor scale is often raised a semitone; until, in the end, our original scale of "natural" notes comes out:



This is the commonest order of the ascending minor scale; but the other form, with the sharpened seventh only, is also used, while the

"natural" notes series was a great favourite with the old Church music composers, who did not feel anything of the modern desire for a semitonic leading note to the key.

In the descending minor scale the form of the ascent is generally changed so that only the natural notes appear.



The explanation of this apparent vagary is easy enough. In descending, the need of a "leading note" is not felt; and with the seventh note standing at its original pitch, a raised sixth note is also unnecessary. Nevertheless such phrases as these:

are quite common in classical music. The student will find, as his theoretical and practical knowledge advances, that the minor scale is subject to many whims on the part of composers.

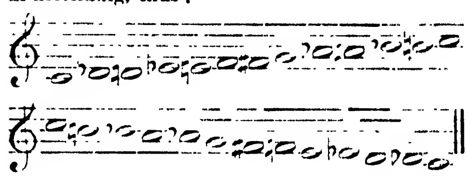
Return now to the subject of key-signatures. We have seen how these signatures are used to represent certain major keys. In addition to this, they denote also certain minor keys, known technically as the "relatives" of respective major keys. Two keys or scales are said to be relative when they contain the same, or nearly the same, notes. Thus, a scale of "natural" notes beginning and ending on A is "relative" to the scale of C major. In other words, when notes which are natural, sharp, or flat in one key are natural, sharp, or flat in another key, they are called "relative." Here, however, the student must remember that such sharps or flats as may be used for the 6th and 7th degrees of the minor scale are not included in the key-signature, but are prefixed to the notes as they occur.

Strictly speaking, it is incorrect to say that "the keys C major and A minor are relative keys because in each all the notes are natural," for in A minor, as generally written, all the notes are *not* natural. So far, however, as the key-signature is concerned, the theory of "relative" keys holds good. Every key-signature represents not only a certain major key, but also its relative minor—the key which stands a minor third below the major keynote. Thus, a signature of one sharp means either G major or E minor; four flats A♭ major or F minor. Here is a table which will be serviceable to the student in this connection:

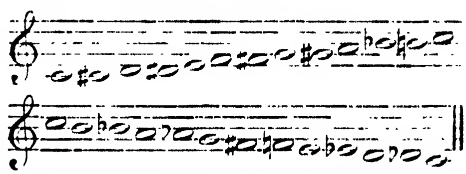
Major and Minor Scales having the same Signature.

C Major	A Minor
G ,, ...	E ,,
D ,, ...	B ,,
A ,, ...	F♯ ,,
E ,, ...	C♯ ,,
B Major	G♯ Minor
F♯ ,, ...	D♯ ,,
C♯ ,, ...	A♯ ,,
F ,, ...	D ,,
B♭ ,, ...	G ,,
E♭ ,, ...	C ,,
A♭ ,, ...	F ,,
D♭ ,, ...	B♭ ,,
G♭ ,, ...	E♭ ,,
C♭ ,, ...	A♭ ,,

One more scale has to be considered, namely, the *chromatic*. A diatonic scale is made up of tones and semitones; a chromatic scale moves entirely by semitones. Thus, if you sit down to the piano and sound *every key*, black and white, from one C to the next C, you produce a chromatic scale. In theory there is no difficulty about the chromatic scale: in the matter of writing it there is considerable difficulty and no little confusion. Some theorists write it so as to make it notationally the same in descending as in ascending, thus:



With other theorists it takes this form—



Still others would write the ascending B♭ and the descending F♯ here as A♯ and G♭. For facility in performing, perhaps the form of ascent by sharps and descent by flats is to be preferred; but the other forms are more scientific and better suited for harmonic purposes. This, however, is a point which can be appreciated only by advanced students.

In order to facilitate reference to the respective degrees of the scale apart from the pitch, the following technical names are in use:

1st degree	Tonic or Keynote.
2nd ,, ...	Supertonic.
3rd ,, ...	Mediant.
4th ,, ...	Subdominant.
5th ,, ...	Dominant.
6th ,, ...	Submediant or Superdominant.
7th ,, ...	Leading note or Subtonic.

These terms find their most frequent use in the study of harmony, for which purpose they must be carefully committed to memory.

So far we have familiarised ourselves with three intervals only—the tone, the semitone, and the octave. We are now prepared to look at the subject of intervals in more detail. It is hardly necessary to give a definition of the term interval,

which is readily described as the distance from one note to another. Intervals are generally reckoned upwards, and are named by the number of scale sounds they contain, the extremes being included in the reckoning. Thus, from C to F is a fourth, because four notes are involved; from D to A is a fifth, because five notes are involved; and so on. The numeral of any interval is thus quite easily ascertained. But we must go farther than this. One third (C to E, for example) may cover four semitones, while another third (say, D to F) covers only three. It is this distinction which leads to the use of the terms major and minor (greater and lesser), perfect and imperfect, as applied to intervals. The seconds, thirds, sixths and sevenths are known as major and minor; the fourths and fifths as perfect and imperfect. In the following table the number of semitones of which each interval is made up is given. As Stainer says, it is quite unnecessary to commit to memory the number of semitones contained in all the possible intervals.

TABLE OF DIATONIC INTERVALS.

Minor second	1 semitone.
Major second	2 semitones.
Minor third	3 "
Major third	4
Perfect fourth	5
Pluperfect (or augmented) fourth	6
Imperfect (or diminished) fifth ..	6
Perfect fifth	7
Minor sixth	8
Major sixth	9
Minor seventh	10
Major seventh	11
Perfect octave	12
Minor ninth	13
Major ninth	14

No interval is reckoned beyond a ninth, which is indeed itself, regarded as a compound second. With this exception, intervals which exceed the octave are generally regarded as replicates of those that do not. In the case of the pluperfect fourth and the imperfect fifth, one or two points have to be observed. Both intervals contain six semitones, but in the one case four and in the other case five scale letters are involved:

The pluperfect fourth covers three whole tones, for which reason it is sometimes called the tritone. Only one pluperfect fourth and one imperfect fifth are found in the diatonic scale, the first always on the subdominant and the second always on the leading-note. For this reason they have their own peculiar names.

All these intervals are known as diatonic intervals because they occur in the unaltered diatonic scale. But just as we have our chromatic scale, so we have our chromatic intervals. Suppose we take from the chromatic scale these two pairs of notes:

It is clear that neither pair belongs to any diatonic scale. The first is greater, by one semitone, than a major sixth; the second is less, again by one semitone, than a minor sixth. Therefore both must be chromatic intervals: they cannot be traced to any key. In short, a chromatic interval is an interval not found in the diatonic scale. Such intervals are of two kinds—augmented and diminished. These terms are self-explanatory, the intervals to which they are applied being augmentations and diminutions of diatonic intervals. When the interval is greater by a chromatic semitone than the major or perfect interval it is called augmented; when it is less by a chromatic semitone than the minor interval it is called diminished.

Students are at first apt to confound augmented seconds with minor thirds, augmented fifths with minor sixths, etc., these having the same number of semitones between them respectively. The error is easily avoided by counting the stave letters which are involved. Thus, A to C must always be a third, because three letters (A, B, C) are involved. The augmented second, A to B♯, contains the same number of semitones (three), but only two letters are involved. We may sharpen or flatten one or both notes of an interval, but the process can never alter the number of degrees in the interval; only the *quality* of the interval is affected. It must be admitted that a good deal of practice is required in order to attain the ready naming of intervals, but practice will assuredly bring perfection.

Reading Music. It has been said that a musician ought to be able to "read" notation as one reads a book. The process is hardly analogous; for the musician has usually to convert his reading into practice—a singer by his voice, a player by his fingers—whereas the book-reader has only to allow the impression of the words to act automatically on his brain. But undoubtedly facility in the reading of his notation is a great point with the musician. It is only to be acquired by much practice; in particular by constant and systematic reading "at sight." In taking up a piece, always look carefully at the key and time signatures. Be sure of your "scale"—of what notes are sharp or flat. Remember the transitions to other keys that are most likely to occur. If you are a singer, it is best to read by the movable *Doh*; that is, find out on what line or space the *Doh* (or keynote) is, and then calculate the other intervals accordingly. Vocal reading without reference to the key relationship of the tones is at best a tedious and uncertain method, to be acquired indeed only by exceptional persons. To the player a practical knowledge of harmony is of inestimable value in the "reading" of music.

THE MARVELS OF THE CELL OF LIFE

The Vegetable Kingdom. The Essential Unities and Differences of all Forms of Living Matter. Nature's Economy of Energy

By Dr. GERALD LEIGHTON

EVEN the most superficial observer cannot fail to be struck with the immense variety of creatures amongst the Invertebrates, and also with the fact that some groups have very little in common with others. There is no common plan of structure or type as was seen in the five Vertebrate groups. On the other hand, each group of Invertebrates is on the same footing as the whole Vertebrate group, for each has its own type of growth. No two animals could be more unlike each other than a star-fish and a tape-worm, or an oyster and a flea. To emphasise the *existence* of these wide divergences is our present purpose, preparatory to enquiring into their mode of origin: more detailed information concerning their structure and life-history will be found in the Natural History section of this work.

Animals and Plants. Having taken this brief survey of the animal world, we may turn our attention for a moment to the other great division of living matter, the vegetable kingdom, and see wherein lies the distinction between animals and plants.

The science of Life, Biology, is concerned with *all* living things, whether they be plant or animal, and deals with every possible point of view. It is only concerned with inanimate matter in so far as minerals are concerned in building up animal or plant bodies, or in the study of mineral bodies or fossils of plants and animals. The non-living objects in the Mineral Kingdom all show the following characters: Their chemical composition is relatively simple, being either a single element like gold, or simple compounds of two or three elements, as common salt. When unmixed, all mineral bodies are composed of similar particles, that is, they are *homogeneous*. In form and shape they are either indefinite (*amorphous*), or crystalline; in the latter case the shapes are made of plane surfaces and straight lines. If they show any increase in size, as, for example, some crystals, the increase is due to simple accretion of matter, and not to any true process of growth in the ordinary sense. Finally, all minerals agree in this, that all their phenomena are physical or chemical purely, and there is no tendency to periodic changes of any sort whatever, such as characterise living tissues. It follows that the study of non living matter is embraced in the sciences of Physics, Chemistry, and Mineralogy.

Five Characters of Living Matter. If we compare these non-living objects with animate matter, we find that there are a number of points in which all living things, both plant and animal, differ from them and have in common with each other. To begin with, the chemistry of living matter is that of comparatively few chemical elements, of which *carbon*, *hydrogen*, *nitrogen* and *oxygen* are the most important. These four elements are combined to form what are termed complex organic compounds, all of which contain a considerable proportion of water, and are easily decomposed. Next, all living tissues are largely composed of the substance called *protoplasm*, a substance which is in itself homogeneous, but which has the capacity by its growth of giving rise to *heterogeneous* tissues adapted for various functions; in other words, it can grow into different *organs*. Whether it thus grows or not, all the phenomena of Life are bound up in this protoplasm. Thirdly, as has been already inferred, living things are able to *grow* in the true sense of that term. That is to say, they can take into themselves matter from without, and so act upon it that it becomes part and parcel of their own living selves. This process is termed *assimilation*. Next, in contrast to the fixed stability of minerals, living tissues are in a constant state of change; indeed, it is this never-ceasing change which results in the cycle of alterations constituting Life.

Finally, and most characteristically, all living cells or bodies have the marvellous power of detaching or setting aside portions of themselves which, under favourable conditions of nutrition and environment, are capable of developing into cells or bodies similar to those from which they were separated. In a word, living cells possess the power of *Reproduction*.

The Physical Basis of Life. Every object which exhibits these five characters is either a plant or an animal; it is alive, and it has its life in virtue of being composed largely of protoplasm. It is for this reason that protoplasm is termed the physical basis of life, and this makes it a matter of importance to study the characters of protoplasm a little more closely.

The relation of protoplasm to the structure of the individual cell will be found fully dealt with in the section of this work devoted to PHYSIOLOGY. We wish at this point to draw attention merely to the fact that three great living characters are bound up with this substance. They may be termed the essential vital phenomena.

The first of these phenomena is that of *Metabolism*. Protoplasm is a very unstable substance, because of its chemical complexity and its large proportion of water. It is therefore constantly being destroyed and as constantly

renewed. The processes concerned are those of metabolism. When destructive and constructive metabolic processes balance each other the living organism remains stationary: this is characteristic of the mature organism. If assimilation is in excess of destruction growth ensues, if destruction is in excess of assimilation the living matter becomes less and death finally follows.

The second phenomenon associated with protoplasm is *Irritability*, or the power of responding to external and internal impressions, or *stimuli*. It is in virtue of this power that living matter is enabled to bring itself into relation with the world around it. The result of the irritability is seen in the power of movement or possessing sensation. In the higher animals special parts are set aside to receive these *stimuli*, and the animal is conscious of the impressions. This consciousness of an impression cannot be definitely said to exist in the lowest forms of life, but, on the other hand, neither can its existence be absolutely denied. The difference is only one of degree, not of kind.

Thirdly, living protoplasm, alone of all substances, is capable of *Reproduction*, of detaching parts of itself enabled to live independently as separate individuals.

The Work of a Single Cell. Here we come face to face with one of the most wonderful facts of Biology, namely, that all the functions which are necessary in order to constitute a living thing can be carried out by one single cell. The processes of nutritive metabolism resulting in growth, the manifestation of irritability in response to *stimuli* from without or within, and, finally, the power of reproduction, can all be seen in one minute simple mass of protoplasm, which because of these capacities is a living entity. Moreover, in the simplest of these *unicellular* organisms, whether they be regarded as plant or animal, any part of the protoplasm can perform any one of these functions. At one moment assimilation of nourishment is going on, at another moment a process of protoplasm called a *pseudopodium* is thrown out in response to some stimulus, and at a later stage this same protoplasm may be seen to detach itself from the mass and begin a separate individual existence capable as was the whole mass of all these functions.

All this is true of animal and vegetable protoplasm alike, and if the question be asked, "How does a plant differ from an animal ?" it follows that the distinction must be a somewhat artificial one, since the essential vital phenomena in both are identical. It is simple enough to tell a higher animal from a plant by reason of the possession by the animal of organs for locomotion and sensation, and because higher animals have a definite internal cavity for the reception and digestion of food. There is a definite difference in their *structure*. But the simplest one-celled animals and the lowest plants exhibit no essential difference in structure, and they can only be separated by the different ways in which they live their life, in other words, by differences in *function*.

Unity of Essentials. It is true that there is to a certain extent a chemical difference to be found between animal and vegetable cells, *albuminoids* being characteristic of animal cells, while *cellulose*, *starch* and *gum* occur more in the vegetable. *Chlorophyll*, the green colouring matter of plants, is very characteristic—in fact, any cell which has a covering of cellulose and contains *chlorophyll* within it is regarded as almost certainly vegetable. But the difficulty arises that both of these so-called characteristic vegetable substances are found in animals. Cellulose occurs in the covering of Sea-squirts, and a number of the lower fresh-water animals contain chlorophyll. It is also true that animals and plants agree in essentials as regards their methods of reproduction, and also in the way in which they exhibit relationship to the surrounding world. Not necessarily in detail, but in essentials. Organs of locomotion and organs of special sensation are, of course, more obviously present and more highly developed in animals, but it is a difference of degree merely, not of kind, and in the lowest animals and plants the difference is imperceptible.

But when we come to study the nature of the processes of nutrition in plants and animals we find there some real distinctions.

The Life-power of Plants. "Plants, as a whole, differ from animals in possessing the power of converting certain of the *inorganic* substances which occur, independently of life, in the earth and its atmosphere into the more complex *organic* substances which are found in living beings only. The *food* of plants consists of *carbon dioxide* (carbonic acid), ammonia, water, and certain mineral salts, these being, all of them, materials which occur in nature independently of life. As the materials composing the food of plants are all gaseous or liquid, or occur in solution in water, plants require no special aperture for the taking in (*ingestion*) of their nourishment. Out of these stable inorganic compounds the plant has the power of building up protoplasm and the other unstable organic compounds of which its tissues are composed. More especially, plants possess the power, denied to all undoubted animals, of breaking up or decomposing carbon dioxide, retaining the carbon of the same, and setting free the oxygen. For the exercise of this power, however, two conditions are requisite, *viz.*, the presence of sunlight and the existence in the plant-tissues of *chlorophyll*" (Nicholson).

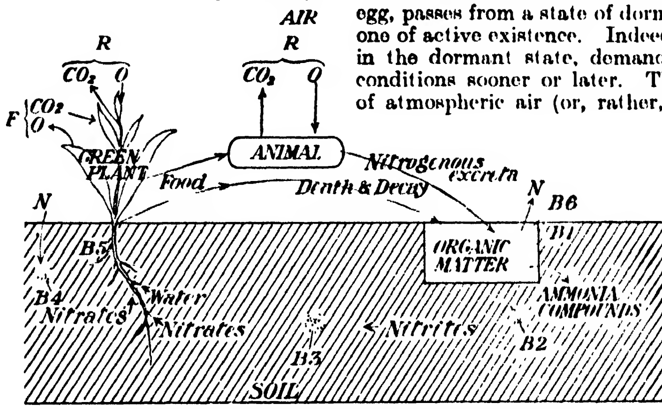
"Animals, in fact, differ from plants in requiring as food complex organic bodies, which they ultimately reduce to very much simpler inorganic bodies. The nutrition of animals is a process of oxidation or burning, and consists essentially in the conversion of the energy of the food into vital work, this conversion being effected by the passage of the food into living tissue.

"Plants, therefore, are the great manufacturers in Nature; animals are the great consumers.

"The *Fungi* are, however, economically speaking, animals. There are also various *carnivorous* plants (the Sun-Dew, Venus's Fly-Trap, etc.), which are genuine plants in so far that they can decompose *carbon dioxide* and build up starch, but which, nevertheless, have the power of digesting and absorbing ready-made organic materials in precisely the same way as animals do" (Nicholson).

Breathing. As regards the process, or function, of respiration it is essentially the same in all living tissues, plant or animal, but the two groups react differently upon the atmosphere. Both add carbon dioxide to the air as the result of breathing—animals by exhaling this gas into the air or water. In plants, however, respiration is much less energetic, and the carbon dioxide, as a result, much less in amount: and not only so, but this substance is actually employed by the plant as food. "Hence, during the day-time, the green parts of plants are constantly exhaling oxygen gas into the atmosphere, the evolution of carbon dioxide being masked or neutralised by the process of digestion. There is thus maintained an approximate uniformity in the amount of carbon dioxide present in the atmosphere. Animals, by their respiration, and by the decomposition of their bodies after death, are constantly adding carbon dioxide to the atmosphere, and at the same time are incessantly abstracting oxygen. Plants, on the other hand, during the day-time constantly remove carbon dioxide from the atmosphere, and add oxygen to it. Hence a balance is kept up, the members of each great division of living beings adding to the atmosphere the ingredients necessary to the life of the other" (Nicholson).

We are thus brought face to face with one of the most marvellous facts of biology, a fundamental principle which it is necessary to clearly understand at the very outset. It is Nature's unique plan of economising the energy of life, and the more its details are studied the more wonderful does it seem. Professor Ainsworth Davis's diagram, which we reproduce, is as simple as it is instructive [3].



3. THE RELATION OF PLANT AND ANIMAL LIFE

Arrows indicate the taking in or giving out of substances. Both green plant and animal take in oxygen [O] and give out carbon dioxide [CO_2] in respiration [R]. The animal feeds on plants, and by nitrogenous excretion and ultimate death adds to the store of organic matter in the soil. The green plant in feeding [F] takes in carbon dioxide [CO_2] from the air, returning oxygen [O], and also takes up water with dissolved salts from the soil; its dead parts contribute to the organic matter in the soil. The groups of bacteria [B1–B3] produce ammonia compounds, converting these into nitrites, and these again into nitrates. The bacteria [B4], and the tuberclefungi [B5], fix the free nitrogen [N] of the air, with production of nitrates. The bacteria [B6], in absence of oxygen, decompose organic matter with liberation of free nitrogen [N].

Dormant Life. So the active life of the world goes on, one process waiting upon another, every part of the complicated machinery doing its appointed piece of work. But even this is not all the marvel. In addition to the phenomena of active life, we find that there is a condition of cells which may be termed *Dormant Life*, in which it is impossible to say whether the cells are alive or dead, except that under certain conditions they manifest the phenomena associated with the active phase of existence. This dormant life is seen in the seeds of plants, and in the eggs of animals. In the cells composing these there is protoplasm, but no external manifestation of vitality, and under certain circumstances this absence of the evidence of life may persist for a very long period. In other words, certain environments are indispensable; they form the conditions of active life.

If these conditions are satisfied, the seed, or egg, passes from a state of dormant vitality into one of active existence. Indeed, life itself, even in the dormant state, demands some of these conditions sooner or later. Thus the presence of atmospheric air (or, rather, of free oxygen) is in an ordinary way essential to active life. The higher manifestations of vitality, again, are only possible between certain limited ranges of temperature, varying from near the freezing point to about 120° Fahr. Water, again, is essential to the carrying on of vital processes of all kinds. Hence the mere drying of an animal or plant will, in most cases, kill it outright, and will always suspend all visible vital phenomena.

Organised Life. Lastly, the great majority of living beings are *organised*—that is to say, they are composed of different parts or organs, which hold certain relations with one another, and which discharge different functions. It is not the case, however, that organisation is a necessary accompaniment of vitality, or that all living beings are organised. Many of the lower forms of life exhibit absolutely no visible structure, and cannot, therefore, be said to be "organised." Animals are organised, or possess structure, because they are alive; they do not live because they are organised.

It follows from this statement that some living things have ***absolutely no visible structure***

—that all the functions necessary to life, namely, nutrition, growth, reproduction, and functions of relation, can be carried out by one single cell, and this is one of the most marvellous facts in biology. Moreover, any part of that cell may be able to perform any one of these vital functions, or even all of them at different times. In a word, there is as yet in these simple forms of living matter no such thing as *Specialisation of Function*, which we see in higher forms. This is a point of very great importance and interest, because it is in the setting apart of special cells or parts of a cell for special work that is seen the first sign of the great process of evolution which ends in the characters of complicated and highly intelligent beings.

Vital Functions. A good example of a living creature performing all the vital functions in one single cell, each part of that cell acting with perfect indifference as a nutritive organ, a reproductive organ, or an organ of relation, is seen in the *unicellular Amœba*. Here no particular part of the protoplasm is set apart for any special work, there is no organisation and no specialisation of function. If an *Amœba* be watched under the microscope it will be observed to wrap itself around any minute particles which it encounters, by way of taking in nutriment. A little later the same protoplasm which absorbed the food particle will throw out a finger-like process (a *pseudopodium*) as a feeler, thus acting as an organ of relation. Still later, the same protoplasm actually divides itself into two, producing two complete individuals by a simple process of *fission*, or perhaps by throwing out a *bud*, which separates itself from the larger mass and floats off as a separate individual. Here the same protoplasm which had already manifested its power as an organ of nutrition and as one of relation now shows that it is also capable of performing the part of a reproductive organ.

Immortal Life. Now comes a great and wonderful thought. Since the original individual is by its division converted into two new individuals, it follows that in the history of a creature such as an *amœba* death is not a necessary phenomenon. In fact, we may truly say that an *amœba* is immortal. Its own protoplasm becomes that of its progeny by direct conversion of the parent into offspring. The parent is not everlasting, but it may be, and often is, deathless and in a real sense immortal. Besides all this, if we watched our amœba still further, we might observe it throwing out from its interior some particle which could not be assimilated, in other words, performing the function of excretion. By means of changing its shape and its *pseudopodia* it will move about; it has the power of locomotion, and, as is seen by its withdrawal from an irritating point, it possesses in some rudimentary degree what in higher forms we term *sensation*. This is the earliest sign of anything in the shape of consciousness that can be discovered. It cannot be asserted that a single cell has actually what we understand by that term, but, on the other hand, it cannot be denied.

So by the study of one of these simple *Protozoa* we find that every function which we recognise as necessary to Life can be performed by one single cell without any organisation or specialisation of its parts. We shall see later how this simple method of living becomes more complicated in higher forms, and how functions become separated from one another for the greater perfection and evolution of living things.

The Study of Living Beings. It is necessary now, in order that we may pick up all the threads of our subject in such a way that when put together they may form an intelligible whole, to ask ourselves, before proceeding further, from what aspects we can study living beings.

It is quite obvious from what has already been said, that every living being, whether animal or plant, can be studied from various points of view, each point of view constituting a special branch of biological research. We have traced our single cell until we find it is about to introduce us to more complicated beings, consisting of many cells with different functions, and before we are ready to enter upon that study, we must be quite clear about all that is involved in it. The question is: What are the various aspects in which a living being must be studied in order to see its life as a whole?

In order to answer this question, let the reader make use of the imagination, and picture to himself the position he would be in supposing he were fortunate enough to discover a new species of animal. The duty then devolves upon him of drawing up a description of his discovery in such a way that his readers may have a complete idea of its nature. He will probably find that the task of fully describing any one animal is quite beyond his powers. But we may suppose, for the purpose of our illustration, that the discoverer was competent to describe his discovery from every point of view. How would he do it? From what aspects can he approach the study of this creature in order to describe it fully? Some of these aspects are obvious. For example, he would state at the outset of his account what sort of creature he had found. His title would convey this much. His treatise would be headed "Discovery of a New Mammal" or "A New Species of Slug from Patagonia," or something similarly descriptive. If the latter title were the case in point, we see that we are introduced at once to two distinct aspects of the life of the new species. One is conveyed in the statement that it is a *slug*, the other in that it was found in "Patagonia."

Aspects of Study. How does the writer know that this new species is a slug? He can have arrived at that conclusion in only one way with certainty, namely, by studying the structure of the creature and finding that it was built up on the same lines as a number of other forms with which he was familiar and which were called *Slugs*. He has called it a slug on account of its *Morphology*, and from that aspect alone.

This aspect of study includes the general form and appearance of the animal, its shape, colour, possession of limbs, wings, fins, and other obvious external structures, or the absence of these. It includes in addition the study of the internal parts by means of dissection, and if necessary the study of the whole creature, or part of it, under the microscope. By such a study is determined the plan upon which the creature is built, and from its result the creature is placed among the mammals, birds, fish, molluscs, or wherever its place is.

But then, this creature with the structure of a slug was found in Patagonia. That is a statement which concerns its life-history from an entirely different aspect, namely, that of its *Geographical Distribution*, as far as it is known. It includes the investigation of the area which the species now inhabits and the conditions of its existence in those places.

The Life-history of a Slug. Passing from the two aspects of study suggested by the title of the treatise, the writer would then turn his attention to a number of other points of view. He would endeavour or observe and record how the animal lives its life, adapts itself to its surroundings, and discharges all its functions. This is an immense subject, concerning which we have already said something in the preceding pages. It is the aspect of *Physiology*, and it divides itself into the study of the three functions of nutrition, reproduction, and those directed to bringing the animal into relation with the world around it, as before indicated. There is much more involved in this aspect of life than at first sight appears, and as it is dealt with fully elsewhere we need refer no further to it here.

But these three aspects of description, though they would involve much labour, by no means exhaust the matter. Further investigation might lead to the discovery of the fact that this creature, though now so rare and restricted, was at one time of the world's history a much more common animal. If, instead of a slug the new species had been an animal with a bony skeleton, *fossils* might be found of the same character, which would indicate that Time had played a part in the life-history of the species, and this aspect of study, that of the past and present distribution of similar forms of life, is termed *Palæontology*, and presents some most interesting problems and no less interesting results. Thus a fourth aspect is described.

Specific Characters. But one aspect is no sooner dealt with than another claims attention. What is it that makes this animal different from all others, justifying its being regarded as a form new to science? It is a slug, but different from all the other slugs known to exist. What characters has it which are peculiar to itself? Some of its structures are common to all slugs and to some other animals, but there are some which no other animal possesses, and it is on account of these that the new discovery is recognised as a new species. This is the aspect of specific characters, by means of which the organism is classified.

Then there is a special study of the various changes in form and function through which an organism passes before it reaches maturity, a study which is partly of structure, partly of function, but which is now so large a science that it is taken up as a branch by itself, namely, that of *Embryology*.

Evolution. Finally, there is still one other point of view, perhaps the most interesting of all, a point of view which does not concern the living being as an individual, but which devotes attention to the investigation of the origin and history of groups of similar individuals, such groups as are termed species. It is a more or less philosophical aspect, one which studies the connection of one kind of animal with another, their relationships as well as their origin, their association as well as their probable destiny in the future.

This is the point of view of Evolution, the most fascinating portion of the whole of biology, largely a theoretical as well as a practical study. Evolution differs from other aspects of biology in this especially, that it takes no note of the individual, it refers entirely to groups; we do not speak of the evolution of *a man*, but of *man*—not of *a* horse, but of *the* horse, regarding men and horses as species of animals.

We see, therefore, that there are more aspects of the life of an animal than would at first sight appear, and a complete description must take up all these. It is practically impossible for any one man to make himself familiar with all that is known of all these aspects, even in relation to a very few animals. Each aspect is a study so far-reaching in itself that one of them is more than most students can learn thoroughly.

Seven Aspects of an Animal. The point is this, that it is of importance in describing an animal to remember that all these aspects must be considered before a complete description has been given. Of them all, the two most important from the standpoint of the ordinary reader are the aspects of structure and function, morphology and physiology; hence it is to these that we shall pay special attention here.

Summarising this, we see, therefore, that in order to give a fully complete description of an animal, the creature must be dealt with from the standpoint of its

Morphology or Structure,
Physiology or Functions,
Geographical Distribution,
Palæontology,
Classification,
Embryology,
and Evolution.

We shall see later that Physical and Mental Evolution proceed along similar lines, and must be studied by means of similar scientific methods.

To be continued

Group 8 **DRAWING** 2	# MODEL DRAWING, WITH PRACTICAL GEOMETRY **A First Lesson in Object Drawing. Measuring. Light and Shade. First Principles of Perspective. Instruments in Practical Geometrical Drawing**

By WILLIAM R. COPE

Model or Object Drawing. When a person wishes to make a drawing of any real object, he has many difficulties confronting him, which he did not have in freehand from the flat copy. He has now to give the representation of an object in the "round," on a flat surface of paper or canvas. Therefore his perceptive faculties will need still further careful guidance with reference to *how to see* an object, whether it be its apparent form, tone, or colour.

At present we shall deal chiefly with the apparent *form*, leaving tone and colour until the student is more advanced. It will be noticed that we have spoken of the *apparent* form of an object, and this is the first great stumbling-block to all beginners in object drawing. They so very often draw the *real* instead of the apparent shapes, and then cannot understand why their drawing does not appear like the object. There are so many optical illusions with regard to the appearance of an object, that, without a thorough method of explanation of *how to see*, the student is bewildered and sometimes gives up in despair.

Two Important Rules. There are several rules which will be helpful, but the two most important are:

1. Draw the *apparent* shape of an object, and not what you know is the *real* shape. Occasionally it happens that the *apparent* is the same as the *real* shape of an object, but still the above rule holds good.

2. In any objects, those edges which are *really parallel* to one another, and *recede from the spectator*, always appear to converge to some point.

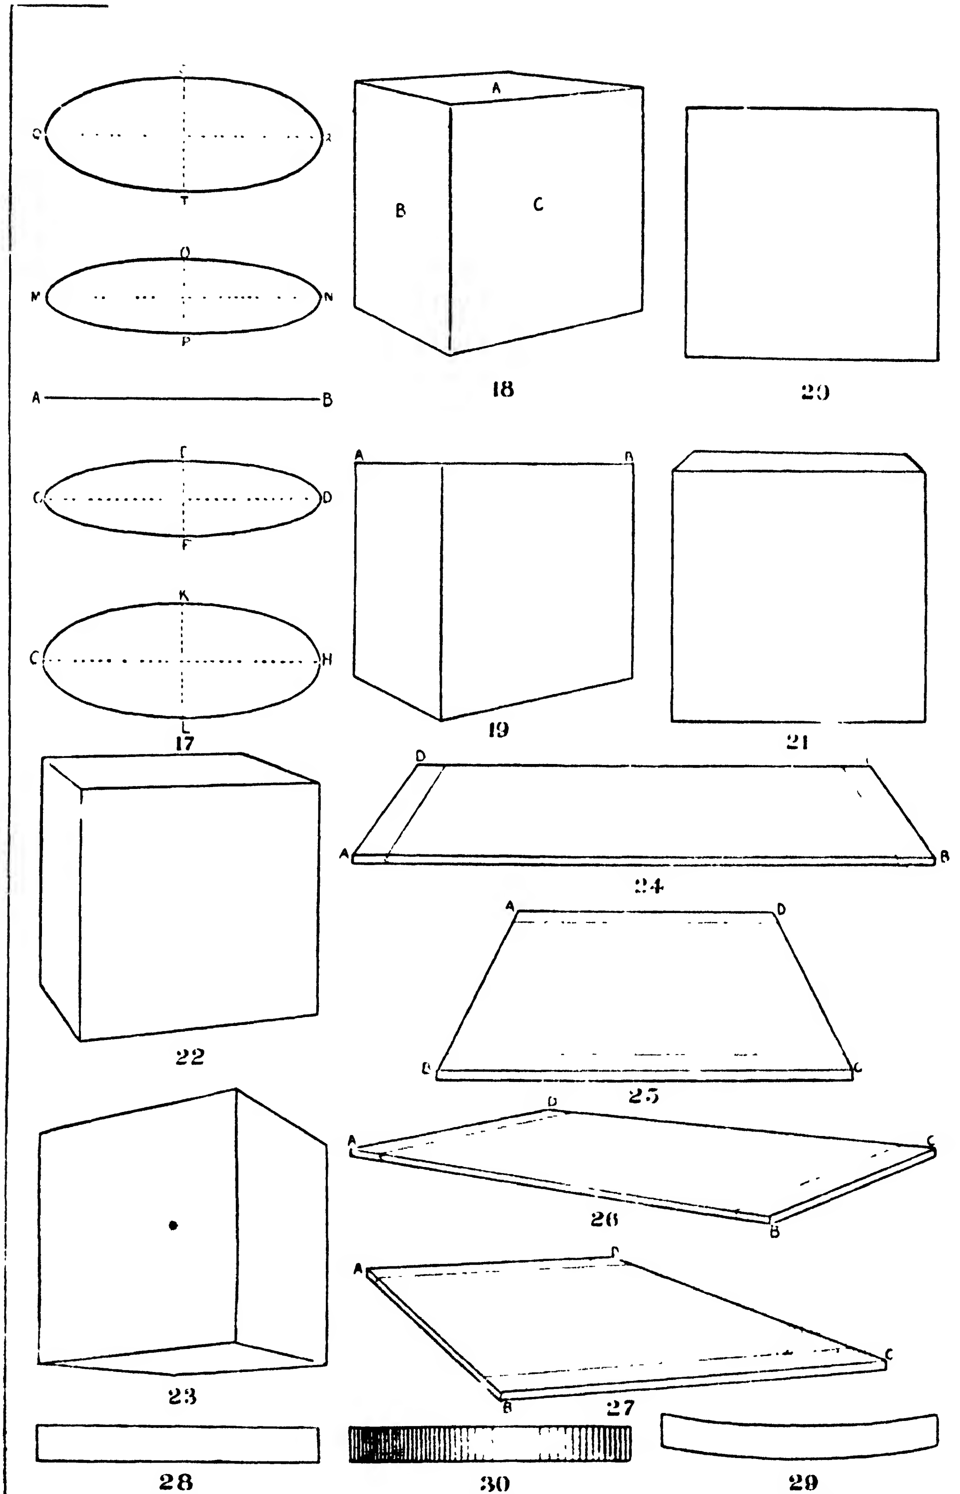
For explanation of the first rule we will take a circular hoop made of thin stiff wire, so that we can neglect its thickness. If the hoop be placed in a horizontal position on a level with the eyes, the student will see an appearance like *AB* in **17**. That is, a *straight* line must be drawn for the representation of a circle in such a position. This, to a beginner, is incredible at first, but he can easily prove that the apparent shape of the circle is a straight line, by holding horizontally, and on a level with his eyes, the straight edge of a ruler between his eyes and the object. He will observe that the real curve of the hoop *appears* to lie exactly straight and level with the edge of the ruler.

If the hoop be placed still in a horizontal position, but this time *below* the eye level, the student will see a shape like the ellipse *CFDE* in **17**. Here the distance *EF* is *apparently* much less than *CD*, but in *reality* they are equal. When the hoop is placed further below the eye, and still in a horizontal position, an ellipse of different proportion is seen as indicated in *GLHK* in **17**. Again placed in a horizontal position, but *above* the eye level, an ellipse like *MPNO* will be seen. Moreover, if the distance above the eye level is just the same as that below, and the hoop is exactly the same distance from the observer, this ellipse *MPNO* is the same size in every respect as the ellipse *CFDE*; but it must be remembered that the apparently upper curve *MON* now represents the *nearer* part of the loop, and *MPN* the *further* part, whereas, when below the eye level, *CFD* represents the nearer part, and *CED* the further.

If the hoop is placed higher still and horizontally, an ellipse like *QTRS* will be seen, and this will be exactly the same size as *GLHK*, if the respective distances, above, below, and from the eye are kept equal in each position. The student should also observe that the major axes *AB*, *CD*, *GH*, *MN*, and *QR* are always the same length, at whatever level (within the field of vision), if the hoop is placed at the same distance from the spectator, but the minor axes vary in length. The general tendency of all beginners is to make these minor axes too long.

The Cube. We will now take a cube as an example for more fully explaining the first rule. It is well known that each of its six faces is *really a square*, but it is, of course, quite impossible to see all these faces as squares at the same time; in fact, if we use an opaque cube, we cannot see, at the same time, more than *one* face as a *square*, and this only in a particular view. More often all the visible faces are nearly, but not quite, parallelograms. Look at **18** (which is the correct representation in outline of a cube when viewed from a particular point), and it will be seen that the faces *B* and *C*, more especially *A*, are not *squares* in this representation, for the angles are not right angles, the four sides of each surface are not equal, nor are certain pairs of opposite sides parallel. That is to say, by drawing the *apparent* shapes of *really* square surfaces, we obtain, as far as outline alone can give us, the true appearance of the object.

A real square face may even be represented by a line only, as for the top surface of cube in **19**, which is the appearance of the cube when placed upright, so that its top face is exactly level with the eye. In looking at **20**, we do not, at first, realise that it is the representation of a cube, but it is the appearance of it when it is placed in a vertical position, and the student is looking at it so that a straight line drawn from his eye to the centre of the visible face of the cube would be at right angles to that surface. He can thus see only *one* face of the cube, which *appears as a square* in shape. The student should now study other different appearances of the cube in various positions, as shown in **21**, **22**.



FIRST PRINCIPLES OF OBJECT DRAWING: DIFFERENT VIEWS OF CIRCLE, CUBE AND BOARD

and 23. The last figure is the appearance of the cube in a certain upright position *above* the eye level.

It often happens that a *short* line must be drawn for a *long* edge of an object, and a *longer* one for a short edge. Figures **24, 25, 26** and **27** are the outline representations of an ordinary drawing-board in various positions. In **25** and **27** it will be noticed that the *long* edges, *AB* and *CD*, of the board are drawn *shorter* than the *short* edges *AD* and *BC*. In certain positions these different edges may *appear* equal.

The eye is so easily deceived by what we *know* is the real length or size of an object, that our judgment is misled. Therefore we must have a means by which we can prove whether the judgment is correct or otherwise. The student must consistently persevere in first judging carefully with the eye alone, and afterwards test by measuring with a pencil held between the eye and the object. With regard to the method of holding the pencil for making tests, there are one or two important facts to be kept in mind, otherwise the test is worse than useless. The pencil must *always* be held at *full* arm's length, and at right angles to a line drawn from the eye to the object viewed.

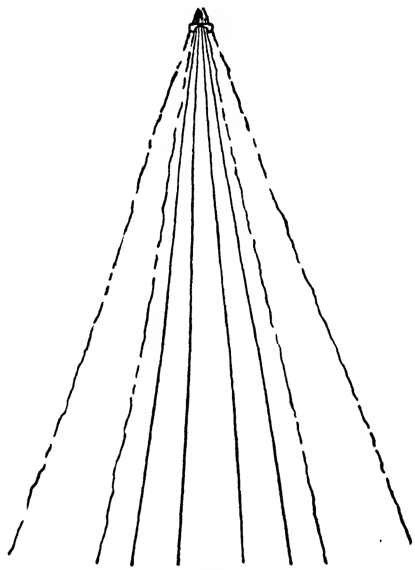
Measuring an Object. To be convinced of the necessity of this, the student should hold the pencil as just advised, and measure on it the apparent length of some horizontal or vertical straight edge, which is at some convenient distance from the eye; then, remaining at the same distance from the object, let him bend the arm a little, so as to bring the pencil nearer the eye, and measure the same edge again. He will find that its apparent length is now shorter than it appeared before. Again, let him bend the arm a little more, thus bringing his pencil still nearer to the eye, and once more measure the same edge. It will be found to appear shorter still. Thus the apparent length of the edge, as measured by means of the pencil, varies according to the distance at which the pencil is held from the eye. Therefore if, consciously or unconsciously, he holds the pencil at different distances from the eye, when comparing the apparent sizes of objects, he is making useless tests at different scales of measurement, he has no fixed standard, and is making the same kind of mistake as would be made by a person drawing a map of England, and using a different scale for each county, commencing with Northumberland at the scale of one inch to a hundred miles, then Durham at three-quarters of an inch to a hundred miles, Yorkshire at half an inch to a hundred miles, and so on. The map, of course, would be worse than useless for judging the relative sizes of the counties or distance from a town in one county to that in another.

It is very difficult to judge when the pencil is held at a *constant* distance from the eye when the arm is bent, but it is easy to know when the arm is at full stretch, and thus a fixed standard of scale is easily established for making accurate comparison of the relative sizes of objects.

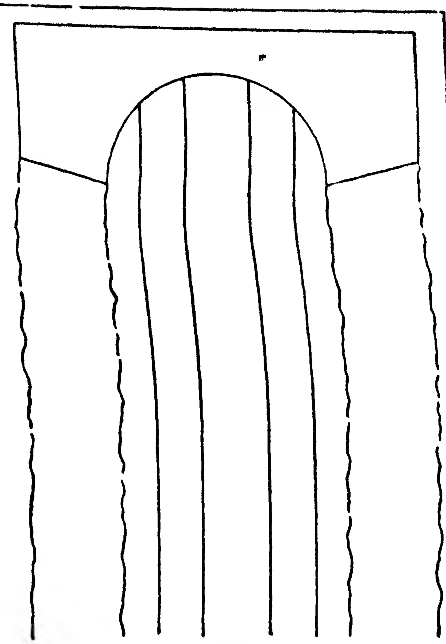
Light and Shade. The light and shade which must necessarily be visible in any object, is a frequent cause of deceiving the powers of perception. Take a shape as represented in **28**. This appears to be an oblong, and, of course, is one; nevertheless, it is also the apparent shape, in outline, of a circular slab, when placed horizontally and on a level with the eyes. Beginners, because they *know* the slab is curved at its edges, draw the representation as in **29**, which is *wrong*. If **28** is shaded, as shown in **30**, the roundness is at once noticed, and yet the actual outline in **30** is an oblong as in **28**. Colour, too, will often deceive the eye with regard to size. A very light-coloured object surrounded by others which are very dark seems to the eye at first to be larger than it is found to be when tested by measurement with the pencil, and, *vice versâ*, a dark one appears smaller. To give the representation of certain objects in outline alone is sometimes more difficult than when rendered by tone and colour, but still these difficulties will be overcome if the student perseveres with the methods advised in this course.

Perspective. When we consider the second important rule of object drawing, we are brought face to face with the subject of Perspective, the theory and practice of which is almost invariably unknown to beginners in drawing. There are many capable artists who say that the rules of perspective are better left alone, but this is often only an excuse for not taking the trouble or not having the desire to study Perspective. The general principles can soon be learnt, and after some practical application of them, all students would do well to go through a good course of study, in which they can learn and practise the rules used in the linear and aerial perspective of objects with their shadows and reflections. It is certainly true that those students, who go through such a course thoroughly, will not only be able to make much more accurate judgment of the appearance of objects, but will also know *why* they must be drawn in a particular way in order to render a true representation of them. We shall confine ourselves to the most essential principles of perspective needed by all beginners in object drawing.

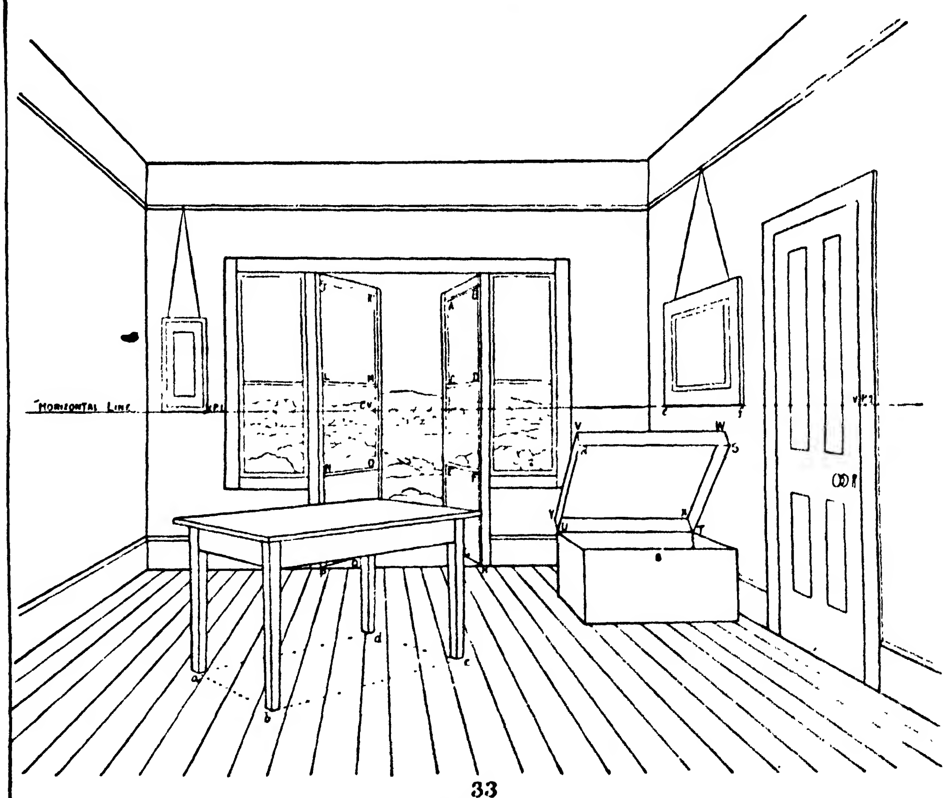
Everyone who has seen a railway or tramway, especially if it is straight, must have noticed that the really parallel metals *appear to converge* as they recede; see **31**, which represents a portion of a railway. It will be seen how well a suggestion of distance is obtained by making the lines converge. Now look at **32** (which is an *incorrect* drawing of the same railway); here we get no suggestion of distance, and the metals, etc., seem to be standing on end with the bridge placed on top. This apparent convergence is true of all parallel edges *which recede* from the observer. Whether they recede straight away in front of him [**33**], or slant away towards the right or left, or even upwards or downwards away from him, as long as they are *receding*, they will be observed apparently converging to



31



32



33

FIRST PRINCIPLES OF PERSPECTIVE RAILWAY AND INTERIOR OF A ROOM

some point, which, is technically called "a vanishing point."

The First Principle of Perspective. Thus we deduce the first principle of Perspective—*edges which are really parallel to one another, and recede from the spectator, appear to vanish to the same point.* In some cases this vanishing point is difficult to determine (unless the student knows the whole theory of perspective), but all *really* horizontal edges which recede *always have their vanishing point somewhere on the horizon line.* This horizon line is always supposed to be on a level with the eye, and its position in relation to other objects can easily be determined by holding perfectly horizontal, at arm's length, a piece of flat cardboard, so that only its *edge* is seen. The student can then see where it appears to cut the objects in view, and by careful observation he will find all receding parallel edges, which are really horizontal, appear to converge to some point on this horizon line.

Look at **33**, where the edges of the frieze and wainscot of the right- and left-hand walls, the floor boards, and certain edges of the door and one picture frame appear to converge to the point *C.V.* (*i.e.* the centre of vision, which is a point on the horizontal line directly opposite the spectator's eye). The edges *AB*, *CD*, *EF*, *GH*, of one door of the window, vanish to the left to *V.P.* 1; the edges *JK*, *LM*, *NO*, *PQ*, of the other door vanish to the right to *V.P.* 2; the long edges of the table, and the dotted lines *ad*, *bc*, on the floor, vanish to the right to *V.P.* 3 (which is outside the limits of the picture); the short edges of the table and the dotted lines *ba*, *cd* vanish to the left to *V.P.* 4, (which is outside the picture); in the lid of the box the edges *VY*, *RU*, *WX*, *ST*, vanish downwards to *V.P.* 5 (below the picture), while the edges *UY*, *RV*, *SW*, *TX*, vanish upwards to *V.P.* 6 (above the picture). It should be noticed that receding horizontal edges *above* the level of the eye appear to converge *downwards*, those *below* the eye level *upwards* to the horizontal line, while those exactly on the eye level, such as *ef* of the large picture, slant neither up nor down.

Parallel Lines. Particular attention should also be given to the representation of the edges of the frieze, top and bottom of window frame, and wainscot of further end of room, also the long edges of the box. It will be seen *they do not converge*, but are drawn perfectly horizontal and parallel, *because they are not receding* from the spectator. Further, upright parallel edges must be represented by *upright* lines, with no convergence for the same reason, see all the upright lines in **33**.

Keeping in mind the very important principles explained in the foregoing paragraphs, the student should now make many careful observations of objects around him, and endeavour to discern the difference between their *apparent* and *real* forms. He will then be well prepared to proceed in drawing some simple objects.

PRACTICAL GEOMETRICAL DRAWING

What Geometry Is. The term *Geometry*, which is derived from two Greek words (*ge*, the earth, and *metron*, a measure) originally signified *land-measuring;* but it now denotes the science of magnitudes in general, with their various properties and relations. We shall follow the *practical* side of Geometry, leaving the *theoretical* side to be explained in the lessons on Mathematics.

The student who possesses a knowledge of Euclid will have a powerful aid in understanding the principles used in practical geometry, and in remembering the methods of construction used in the various problems. We shall bring together those problems which depend for their solution upon some important geometrical truth, thereby not only training the mind to logical deduction, but aiding the memory.

Instruments Needed. The student should always work with the greatest possible accuracy and neatness, for, inaccuracy and slovenliness will undoubtedly lead to disappointment and failure. Whatever instruments are used should be of the *very best quality*, in order to avoid errors and vexation. The instruments need not be numerous, but the following are absolutely essential, and should be used for the purpose mentioned.

1. A half imperial drawing-board and pins, with its adjacent long and short edges perfectly perpendicular to one another.
2. A T-square, which is used for drawing lines parallel to the edges of the board [**34**].
3. Two set squares, having respectively angles of 45° and 60°. These are used to obtain perpendiculars and parallels [**34**].
4. A pair of compasses with movable pen and pencil legs (those with needle points are best, as they do not make large holes in the paper).
5. A pair of dividers for measuring.
6. A mathematical pen for ruling lines in ink.
7. Two pencils, one HH for the construction lines, and the other HB or F for the darker lines of the figure. It is best to sharpen them wedge-shaped, as the points last longer.
8. The paper may be cartridge for ordinary pencil work, but for inked drawings Whatman's or O.W.S. "hot-pressed" surface paper is the best.
9. A protractor, either semi-circular or as a flat ruler; see **35**, which shows how one is marked from the other. This is used for measuring angles in the following method: Suppose we wish to measure an angle of 50° at the point *A* in the line *AB* [**36**]. Place the point *C* of the protractor on the point *A*, carefully keeping the edge of the instrument on the line *AB*, and mark a point *D* opposite the division for 50°, remove the protractor and draw a line from *D* to *A*, then *DAB* is the angle required.
10. A foot ruler, with tenths of an inch marked on it, as well as the usual divisions, and also centimetres and millimetres.
11. Some Indian ink (in liquid form is best). Ordinary ink corrodes the pens.

To be continued

A DICTIONARY OF ELEMENTARY TERMS IN PLANE GEOMETRY

The figures after definitions refer to the illustrations in this section.

An **ACUTE ANGLE** is less than a right angle [44, EFG].

An **Acute-angled Triangle** has all its angles acute [53].

Adjacent Angles have a common vertex and one common arm. In 46, the angle ABC is adjacent to ABD.

Altitude of Triangle. See Triangle.

An **Angle** is the inclination of two straight lines which meet in a point, called the **vertex** of the angle.

The size of an angle does not depend upon the length of the lines forming it, but upon their inclination to each other. In 42 the angle BAC is the same size as the angle DEF.

The sum of all the angles in any one triangle is equal to two right angles, or 180°.

Apex. See Triangle.

An **Arc** is any part [ACB in 64] of the circumference of a circle between any two points in it.

Area. See Figure.

BASE. See Triangle.

To bisect means to cut into two equal parts.

CENTRE OF CIRCLE. See Circle.

A **Chord** is a straight line joining any two points in the circumference of a circle [AB in 64].

A **Circle** is a plane figure contained by one curved line, which is called the **circumference**, or **periphery** and is such that all straight lines drawn from a certain point within the figure to the circumference are equal to one another. This point [A in 63] is called the **centre** of the circle, and each of the straight lines [e.g. AB, AC, AD, AE in 63] is called a **radius** of the circle. The straight line [e.g. CD or BE in 63] drawn through the centre and terminated at both ends by the circumference, is called the **diameter**, which divides the circle into two **Semicircles**; and if two diameters are drawn perpendicular to each other, each of the four parts [CAB, BAD, DAE, EAC in 63] of the circle is called a **quadrant**.

Circumference. See Circle.

The **Complement** of an angle is the difference between it and a right angle. In 45 the angle ABD is the complement of the angle DBC, and DBC is the complement of ABD.

Concentric circles are those which have the same centre but different radii [66].

A **Curved line** is a line that is nowhere straight [39].

DECAGON, a ten-sided polygon.

Diagonal. See Quadrilateral Figure.

Diagonal Scale. See 107-109

Diameter. See Circle.

Duodecagon, a twelve-sided polygon.

An **EQUILATERAL TRIANGLE** has three equal sides [48].

Extreme and Mean Ratio. See 103.

A **FIGURE** is a space enclosed by one or more lines or boundaries, as 47-65. The sum of all the boundaries is called the **perimeter**, and the space within the perimeter is called the **area**.

HEPTAGON, a seven-sided polygon.

Hexagon, a six-sided polygon.

A **Horizontal line** is perfectly level [40 A].

Hypotenuse. See Right-angled Triangle.

IRREGULAR POLYGONS. See Multilateral figures.

An **Isosceles triangle** has two equal sides [49].

A **LINE** has length without breadth, and may be represented by various methods, as **thick, thin, dotted,** or **chain lines** [38].

MULTILATERAL FIGURES, or **polygons,** are figures contained by more than four straight lines [61-62]. **Regular polygons** have all their sides equal [61 and 62], and **irregular polygons** have their sides unequal [60]. Polygons are divided into classes according to the number of their sides; as, the

- **pentagon** [61], having five sides;
- **hexagon** [62], having six sides;
- **heptagon,** having seven sides;
- **octagon,** having eight sides;
- **nonagon,** having nine sides;
- **decagon,** having ten sides;
- **undecagon,** having eleven sides;
- **duodecagon,** having twelve sides.

A **Median.** A line drawn from the vertex of a triangle to the middle point of the opposite side.

NONAGON, a nine-sided polygon.

An **OBLIQUE LINE** is a line that slants [40 C and D].

Oblong. See Rectangle.

An **Obtuse angle** is larger than a right angle [44, HKL].

An **Obtuse-angled triangle** has one of its angles obtuse [52].

Octagon, an eight-sided polygon.

An **Orthocentre.** The intersection of the perpendiculars from the corners of a triangle to the opposite sides.

PARALLEL LINES are such as are in the same plane and never meet though produced indefinitely, but always retain a uniform distance apart [41].

Parallelogram. See Quadrilateral figure.

Pentagon, a five sided figure.

Perimeter. See Figure.

Periphery. See Circle.

Perpendicular. See Right angle.

A **Plane** is a level surface, and is such that, if any two points be taken in it, the straight line joining these two points lies wholly in that surface.

A **Point** has position only, without magnitude, and in practice is usually represented by a dot, as in 37.

Polygons. See Multilateral figures.

A **Problem.** A proposal to do something, such as to solve a question, or to draw a figure, as in 86-103.

A **Proposition** is that which is offered or proposed for adoption or consideration. Propositions are, in geometry, of two kinds, viz., **Problems** and **Theorems.**

QUADRANGLE. See Quadrilateral figure.

Quadrant. See Circle

A **Quadrilateral figure,** or **quadrangle,** is contained by four straight lines, as the square, oblong, rhombus, and rhomboid [54-57]. If the opposite sides are parallel, it is called a **parallelogram** [54-57]. The line joining two opposite angles is the **diagonal,** as AB in 54.

RADIUS. See Circle.

A **Rectangle,** or **oblong,** has its opposite sides equal and all its angles right angles [55].

Rectilineal figures are contained by straight lines, as 47-62.

Regular Polygons. See Multilateral figures.

A **Rhomboid** has its opposite sides equal, but its angles are not right angles [57].

A **Rhombus** has all its sides equal, but its angles are not right angles [56].

A **Right angle.** When a straight line meets another, so as to make the adjacent angles equal, each of the angles is called a right angle, and the lines are said to be **perpendicular** to each other. In 43 the angles ABC and ABD are each right angles, and the lines AB, CD are each perpendicular to the other. It should be observed that **perpendicular** does not mean upright or vertical, but **at right angles to another.**

A **Right-angled Triangle** has one of its angles a right angle. The side opposite this right angle is the **hypotenuse** [AB in 51].

A **SCALENE Triangle** has three unequal sides [50].

A **Sector** is a space enclosed by two radii of a circle [AB and AC in 65], and the arc BC between them.

A **Segment** of a circle is the space enclosed by an arc and its chord [64].

Semicircle. See Circle.

A **Square** has all its sides equal and all its angles right angles [54].

A **Straight line** is the shortest distance between two points.

A **Superficies,** or **surface,** is extension in two directions, and has only length and breadth, but no depth

The **Supplement** of an angle is the difference between it and two right angles. In 46 the angle ABD is the supplement of the angle ABC, and ABC is the supplement of ABD.

A **TANGENT** [A B in 66] is a straight line which touches a circle or curve at one point [C in 66] but does not cut the circle or curve when produced. A tangent to a circle is at right angles to the radius.

A **Theorem.** A proposition to be proved by reasoning.

A **Trapezium** has none of its sides parallel, but two may be equal [59].

A **Trapezoid** has only two sides parallel [58].

A **Triangle** is a figure contained by three straight lines. The side upon which it stands is termed its **base**; the point where the other two sides meet is its **vertex,** or **apex**; the angle at this vertex is the **vertical angle**; and the straight line which is drawn from the apex perpendicular to the base or the base produced is called the **altitude.** Thus in 47, if BC be the base, then A is the vertex, BAC is the vertical angle, and AD is the altitude. Triangles are named, with reference to their **sides**:

1. **Equilateral,** having three equal sides [48];
2. **Isosceles,** having two equal sides [49];
3. **Scalene,** having three unequal sides [50];

With reference to their **angles**:—

1. **Right-angled,** having one angle a right angle [51];
2. **Obtuse-angled,** having one angle obtuse [52];
3. **Acute-angled,** having all its angles acute [53].

UNDECAGON, an eleven-sided polygon.

The **VERTEX** of an angle is the point at which the two lines which form the angle meet.

Vertical angle. See Triangle.

A **Vertical** line is upright [40, B].

Group 10
ELECTRICITY
2

HOW ELECTRIC CURRENTS ARE GENERATED

Concerning Electricity. Its Chemical Properties. Conservation and Emission of Energy. Quantities of Energy and Energy of Motion

By Professor SILVANUS THOMPSON

TO make electricity of service it must be in motion. Our electric supplies are brought to our houses by copper wires or mains, as *currents*.

What precisely electricity is no one yet knows. Apparently it is not solid, liquid, or gaseous. It is invisible and imponderable. It appears to be of a nature different from matter. Matter, whether solid, liquid, or gaseous, possesses different properties when it is in motion from those it possesses when standing still. Matter, so long as it is at rest, can do no work for us, but when moving it possesses available energy. Electricity when at rest is not of the slightest use to mankind; but electricity in motion has many uses.

Generation of Electric Currents. Apparently electricity itself, whatever it may be, is as indestructible as matter. We can neither create it nor destroy it. It exists, usually neutral and inert, everywhere. But man has discovered means of setting it into motion, and of guiding it along conducting wires, and when there is a movement of electricity along a wire or around a circuit we describe such a flow of electricity as an *electric current*. There are many contrivances for setting up or *generating* electric currents; they are known as batteries, dynamos, magneto-electric machines, thermopiles and the like. None of them generate or create any electricity; what they do is to move some electricity which already existed, and set it circulating in the mains. Electric currents are themselves quite invisible; we know them only by the effects they produce. For example, any wire which is conducting an electric current is always more or less warmed by the current which it conveys. If we notice in our streets the places where electric mains are buried, we shall observe, particularly in winter-time, that the ground about them is slightly warmer than the rest of the soil. Snow melts sooner there, and moisture dries off there more rapidly. If a strong electric current is conveyed along a thin wire, that wire may be much heated, may even become red-hot, or be melted by the current. Our glow-lamps are illustrations of the heating effect of the current on a thin wire.

Chemical Properties of Electricity. Again, the conductor which is conveying a current is found to possess magnetic properties, which manifest themselves all round the wire as long as the current is flowing. A common magnetic compass placed over or under a wire that is conveying a current—even without touching the wire—will readily show the existence of this effect. The poles of the compass-needle are neither attracted nor repelled; but the effect of the neighbouring current is to tend to turn the compass-needle into a direction at right angles to that in which the current is flowing. Thus, if a current is flowing in a wire that lies from N.E. to S.W., and a compass is laid over the wire, the current in the wire tries to turn the needle so as to make it point in the direction lying from S.E. to N.W.

Again, if an electric current be led through water by means of wires that lead the current into the water at one side of the containing vessel and lead it out again at the other side—the two wires dipping into the water one at each side—it is found that the water will be chemically decomposed; and by suitable arrangements the constituent gases hydrogen and oxygen can be collected. Thus we see that the electric current possesses chemical as well as thermal and magnetic properties. So, if we can provide proper means for generating electric currents, and guide these currents by wires to the place where we wish to use them, we can cause them at will to produce heating effects—including the emission of light from the heated conductor—magnetic effects, and chemical effects.

Theories regarding Electricity. Although all this has been known for many years, and people are handling electric currents every day, the precise nature of an electric current is still unknown. Some authorities regard it as a flow of electricity inside the substance of the wire, flowing in one direction only, namely from the part called the positive terminal to the part called the negative terminal. More than twenty-five years ago the author gave numerous reasons for thinking that the real flow was, however, in the opposite direction. Others regard the current as consisting of two movements going on at the same time, something called positive electricity flowing in one direction along the wire, while an equal quantity of something called negative electricity flows in the opposite direction.

Another hypothesis is that the current consists solely of minute electrical atoms called "electrons," atoms of negative electricity, flowing through the substance of the copper wire from the negative to the positive terminal, that is in the opposite direction to that assigned in the usual conventions of writers on electricity. It is certain that whichever of these conceptions is true—and they may all be merely different verbal modes of expressing the actual electric movement—the transmission of the energy by the current takes place, not inside the conducting wire, but in the medium surrounding it.

Energy of Electricity. And this brings us to the all-important question of *energy*. For if the electric current is to transmit or convey energy along a wire—even if only to ring a bell—there must be some energy imparted to the electricity to enable it to perform the work required. In other words, before electricity can do anything for us, we must set it in motion—we must generate a current.

In electrical engineering, then, the first principle to be grasped is that of *energy*. Without the expenditure of energy no useful work can be accomplished. All dynamos are but machines for converting into electric energy the energy which is given to them by some prime-mover, a steam-engine, a gas-engine, or a turbine. All electric motors are merely machines for re-converting the electric energy, which they receive by means of the conducting wires or mains, into mechanical energy. All electric lamps are contrivances for converting into luminous energy a percentage of the electric energy that is supplied through the mains. All batteries are but little chemical apparatus to enable us to convert chemical energy into electric energy.

Conservation and Transformation of Energy. One of the greatest intellectual triumphs of the nineteenth century was the establishment of the doctrine of the conservation of energy. Energy can neither be created nor destroyed—it is as imperishable as matter. But it exists in many different forms in the so-called forces of nature, and is capable of being transformed from one kind to another. The sun radiates out to us vast quantities of energy in the form of light and heat. Plants and trees in their growth appropriate or absorb this energy and use it to build up wood out of the chemical constituents of air, earth and water, namely, carbon, hydrogen and oxygen. Coal is but fossilised vegetable matter—a store of energy drawn from the sun's light and heat countless ages ago. When we burn coal we set loose, in the act of chemical combination of the carbon and hydrogen in the coal with the oxygen of the air, the energy that was stored up in the coal, and transform it into the available form of heat.

When we wind up the weights of a clock we expend some of the energy of our muscles,—which we derived in turn by eating food—on doing this work. We *expend* the energy, but it is not lost; it is stored up as energy of position, or *potential energy* in the clock, which, as the weights descend, gradually expends it on driving the movement of the wheels, turning the hands, and keeping the pendulum swinging. When we wind up our watches we bestow a minute quantity of energy on coiling up the spring, and so store up enough to keep the machinery of the watch going for a day. Whenever a movement is forcibly produced against some actively opposing force, as when we raise a weight by exerting a force against the downward pull of the earth—which we call *gravity*—or when we coil a spring by exerting force against the tendency of the spring to recoil, we spend some energy. Another way of stating the thing is to say that we do some work. And, except for inevitable waste due to friction and like causes, the work we do in any such act is exactly the equivalent of the energy that we expend in doing it.

The Measurement of Work. Hence it comes about that we may measure energy, or express the amount of it, in terms of the equivalent quantity of work. A convenient unit in which to express the amount of work done in an operation is the *foot-pound*. This name is given to the amount of work that is done in raising a mass of one pound through a height of one foot against the downward pull of the earth. A pound is heavy only because the earth pulls it. If we could take the lump of iron called "one pound" to the moon it would there weigh far less than it does on earth, because the downward pull of the moon—which is a much smaller globe than the earth—would be far less than the downward pull of our sphere. And even at different parts of the earth's surface the "weight" or downward pull of a pound differs slightly. A pound weighs slightly less at the equator than it does in London, and as one goes toward the North Pole the weight of the pound—that is, the downward pull which it exerts because of the attraction of the earth—becomes slightly greater. This is because the earth is not a perfect sphere.

For precision, therefore, when we speak of the weight of a pound we shall mean its weight when in the latitude of London. And by one foot-pound we shall mean that amount of work which would be done by raising a pound through a height of one foot when the pound is being acted on by the same gravity as that with which it is acted on in London. Now, if we raise two pounds one foot high we obviously do twice as much work as if we raised only one pound—that is, we do two foot-pounds of work. Or, if we raise one pound two feet high we do twice as much work as if we raised it only one foot high; that is also two foot-pounds. So if we raise four pounds three feet high (against the action of gravity as in London) we do four times three, that is, twelve foot-pounds of work. If we raise 100 pounds six feet high, or 50 pounds 12 feet high, or 10 pounds 60 feet high, in each case we do six hundred times as much work as if we raised one pound one foot high—that is, 600 foot-pounds of work.

Quantities of Energy. Now, having got a way of expressing quantities of work, we can readily express quantities of energy in terms of the equivalent amount of work. It is found, for example, by experiment—it was the famous experiment of Dr. Joule—that in warming water the amount of energy that must be spent on a pound of water in order to warm it one degree (of the centigrade thermometer scale) is equivalent to 1,400 foot-pounds of work. It is found by experiment also that the quantity of energy stored up in a pound of good coal is capable, when converted into heat, of warming 7,400 pounds of water one degree, and is, therefore, equivalent to 7,400 times 1,400 foot-pounds; that is, it is equivalent to 10,360,000 foot-pounds

of work. Again, it is found by experiment that a cubic foot of dry steam at a pressure of 180 pounds to the square inch, and at a temperature of 192 degrees (of the centigrade thermometer scale) represents a store of energy of no less than 7,000 foot-pounds, though unfortunately no steam-engines are so perfect as to enable us to utilize the whole of this store. When the steam expands and cools—as it does in the cylinder of the engine or in passing through the blades of the steam turbine—it gives up this energy, or a great part of it, and so drives the machine. When water falls from a height it gives up the potential energy that has been put into it when it was raised up. The sun, by evaporating the seas and the moisture of the earth, raises up water as vapour and then deposits it as rain on the mountains. In doing so, it does a great deal of work—it winds up our waterfalls for us as we wind up the weights of our clocks. If a ton of water—that is, 2,240 pounds—falls down over a cliff 50 feet high it loses 50 × 2,240, that is, 112,000 foot-pounds of energy. But if we divert the falling water and let it fall down a pipe to turn the blades of a water-turbine for us, we shall be able to get from the turbine a large percentage—perhaps 90 per cent. of these 112,000 foot-pounds.

The Energy of Motion. There is another species of energy, namely, the energy of motion—also called kinetic energy—which is possessed by moving bodies. A moving body—a heavy rolling ball, a flying bullet, or a train in motion—possesses energy because it is in motion. It is known from the laws of motion that the energy possessed by a moving body is proportional to its mass and is also proportional to the square of the speed with which it is moving. If the mass be stated in pounds and the speed in feet per second, then the kinetic energy of the moving body can be calculated approximately by squaring the speed, multiplying the result by the number of pounds of mass, and dividing by 64 to bring it to foot-pounds.

Suppose a railway train to weigh 100 tons and to be moving at a speed of 50 feet per second, we may calculate the inherent energy which it possesses as a moving body as follows: The square of 50 is 2,500. The 100 tons are 224,000 pounds. Multiply 2,500 by 224,000, and divide by 64, and we get as the answer 35,000,000 foot-pounds. That is the amount of energy that is in that moving mass: it is the amount of energy that it would expend if it were to be suddenly stopped as in a collision. That is the amount of energy that will be wasted, as heat, in the brakes, if we bring it to rest by putting on the brakes. That is the amount of energy that we should have to put into it to start it again up to full speed.

Power. Another fundamental point in engineering is the precise idea and definition of *power*. Power is the rate at which energy is being spent, or the rate at which work is being done. Suppose a man to be working so hard as to be doing, say, 50 foot-pounds of work per second. He might easily do this by turning the handle of a winch raising 50 pounds a foot high in each second of time. But suppose he is only working half as hard, then the power he is exerting is only 25 foot-pounds per second. More than a century ago James Watt made experiments to find out the rate at which, on an average, during an average shift of work, a horse does its work. He fixed, as a convenient expression, the amount of 550 foot-pounds per second as the value of one horse-power. This is, of course, the same rate as 1,100 foot-pounds in two seconds, or 33,000 foot-pounds per minute, or 1,980,000 foot-pounds per hour. Everyone knows that a horse when stimulated by the whip can exert a much greater power for a short time than it can exert continuously on the average day's work. In fact, a horse can for a few minutes exert five or six horse-power. Similarly a man can for a few seconds at a time exert as much as one horse-power.

The Horse-power. If power, then, is the rate of doing work, it follows that if we multiply the power by the time that it lasts we shall have an expression for the amount of work done during that time. So if a horse-power be 550 foot-pounds per second, then if any engine works at the rate of one horse-power for 300 seconds (=5 minutes), it will by the end of that time have done 550 × 300, that is, 165,000 foot-pounds of work. Or, if it goes on giving out a horse-power for an hour (=3,600 seconds) it will have done 550 × 3,600, that is, 1,980,000 foot-pounds.

Now it is not always convenient to have to use such large figures. For example, if we had to express in foot-pounds the result of 80 horse-power supplied for a week, the figures would be unmanageable. For many purposes, therefore, it is more convenient to think of the amount of work done by a horse-power working for a whole hour (we have just seen that it amounts to 1,980,000 foot-pounds) and simply call it *one horse-power-hour*. Then, since a week contains 7 × 24, or 168 hours, it follows that 80 horse-power supplied continuously for a week would mean a total amount of work done of 80 × 168, that is, 13,440 horse-power-hours.

The Kilowatt. As will be explained in due course, electrical engineers deal with another unit of power called the *Kilowatt* (see ELECTRIC MEASUREMENT). It is about 1⅓ times (or, more precisely, 1·3404 times) as great as the horse-power, for 1,000 horse-power equal 746 kilowatts. In other words, a horse-power is about ¾ of a kilowatt. In fact, while a horse-power is 550 foot-pounds per second, or 33,000 foot-pounds per minute, a kilowatt is 737·2 foot-pounds per second, or 44,232 foot-pounds per minute. If an electric generator is giving out power at the rate of one kilowatt, it will at the end of one minute have delivered electric energy equivalent to 44,232 foot-pounds. Or at the end of an hour, at the same rate, it will have delivered a total amount of energy of 2,653,920 foot-pounds.

Now, this power at the rate of one kilowatt being for one hour's duration, we may call the total amount of electric energy one *kilowatt-hour*. It is usual in commercial dealings concerning electric energy to express amounts of electric energy in *kilowatt-hours*. Indeed, under the Electric Lighting Act of 1882, this amount of energy is described as one "Board of Trade unit," or in ordinary usage one *unit* of electric energy. When that Act was passed the persons or companies supplying electric energy were forbidden to charge as their maximum price more than 8d. per unit, that is 8*d*. per kilowatt-hour. Since that time the price of electric energy has been greatly cheapened, so much so that the great electric power supply companies can supply electric energy to manufacturers at less than 1*d*. per kilowatt-hour. In most towns the supply of electric energy for lighting is usually 4*d*. or less per kilowatt-hour. Where water-power is available, the manufacturers can get electric energy far cheaper, even down to 0·04 of 1*d*. per kilowatt-hour.

We have seen that the kilowatt is about 1·34 times as great as the horse-power; hence the kilowatt-hour—or *unit*—is equal to 1,034 horse-power for one hour. Or one horse-power for one hour is equal to 0·746 kilowatt-hours—or units. It is, therefore, a simple calculation how much a supply of power at the rate of one horse-power ought to cost per annum if the price be, say, 1*d*. per unit. For there are $24 \times 365 = 8{,}760$ hours in a year—reckoning day and night continuously. Hence one horse-power-year equals 8,760 horse-power-hours; or, multiplying by 0·746, equals 6,535 kilowatt-hours, which at the rate of 1*d*. per kilowatt-hour is a total cost of 6,535 pence, or 54·46 shillings, or £27 9*s*. 2½*d*. Manufacturers who might not care to give £27 9*s*. 2½*d*. per annum for one horse-power, running day and night, would probably readily give £10. So if energy can be supplied at as low as ¼*d*. per unit, it will be cheaper to use electric power than to erect small steam-engines in factories.

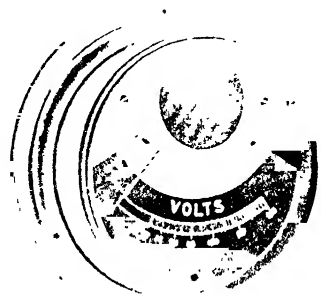
The Essentials—Effort and Movement. Now, before we discuss either batteries or dynamos in detail, we have one other point to make clear. In all cases where power is developed, whether mechanically or electrically, there are two factors to be considered. In the mechanical case one factor is, so to speak, *effort*, the other is quantity of *movement*. There is no power delivered unless both factors exist; and the power is their product. Thus the power delivered by a belt running from one shaft to another depends not only on the pull of the belt, but on the speed at which it is running. If in some particular case the belt-pull is, say, 100 pounds—that is, the tight side pulls 100 pounds more than the slack side—yet it yields no power unless the belt is running. If that belt is running at, say, 3,000 feet per minute, then the power which the belt is transmitting is $3{,}000 \times 100$, that is, 300,000 foot-pounds per minute, or (dividing by 33,000) is about 9 horse-power. If a belt run ever so fast it transmits no power unless there is also the force or effort at the same time: and, be the effort never so great, it delivers no power unless the quantity factor exists also. Electric power also consists of two factors, an effort-factor and a quantity-factor. The electric current, in fact, conveys no electric power unless there is an electric effort present to keep it going.

The Ampere. Names are needed to express these things. Electricians have adopted such names. The amount of a current, sometimes called the quantity of the current, that is flowing, is expressed in terms of a certain unit called one *ampere*. "One ampere" denotes a particular quantity of current defined (by an Order in Council) by the law of England (see ELECTRIC MEASUREMENT). An *amperemeter* (or ammeter) is an instrument [8] which if inserted in an electric circuit will indicate at any instant by the pointing of a hand to a scale the quantity of that current, or, as some people would say, will show how strong the current is. The amperemeter tells nothing about the effort factor, it deals with the quantity only: and a current may be great, of many amperes, and yet deliver very little power, unless there is an effort-factor existing to push the current along. This other factor, the electrical effort with which the current is urged along, has received from electricians several different names. Some call it the electric *pressure*, others the *electro-motive-force* (or tendency to move electricity), others again the electric *potential*. It matters little which name is used if only the thing itself is rightly understood—it is an electrical effort that tends to move the electricity along, tends to drive the current, does, in fact, drive it along, if there is a proper circuit. In some cases, as we shall see, there is an electric effort or electro-motive-force exerted in an opposite direction to a current, and in such cases tends to stop it—just as a resisting effort may occur in a piece of revolving machinery.

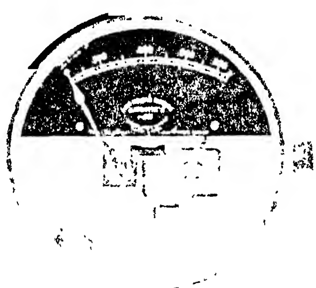
The Volt. The amount of any electric effort, or electromotive-force (whether it be driving the current or opposing the current) is expressed in terms of a unit called one *volt*. "One volt" denotes (again by legal definition, for which see chapter on ELECTRIC MEASUREMENT) a certain definite amount of electric pressure or electro-motive-force. A *voltmeter* [1] is an instrument used to measure the electric pressure, or electro-motive-force, or potential, or *voltage* (all these names are used, and all mean the same thing, namely, *the number of volts*), which has been applied to, or is being generated in any circuit. The mains for house-lighting are usually supplied at a pressure (in cities) of 200 or 220 volts. In private lighting the pressure is more often 100 volts. For tramways a pressure of 500 to 550 volts is usual. For long-distance electric transmission of power extra high voltages of 6,000, 10,000, 20,000 and even 50,000 volts are used. Single voltaic cells have, as we shall see, low voltages of one to two volts only: so to get higher pressures by means of cells we have to arrange a number of them as a battery. Thus, if a Daniell's cell has a voltage of 1·1 volts,

to get by means of such cells a pressure of 100 volts we should have to arrange 91 of them as a battery of cells, all joined up in series. A Daniell's battery to give 1,000 volts would require a row of 909 cells in series.

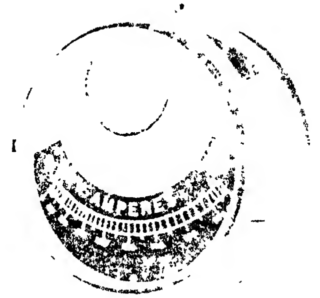
The Watt. Now, when any electric system supplies electrical energy, whether in heat, light, or any other form, the electric power so supplied is the product of the two factors—the number of *amperes* of current, multiplied by the number of *volts* of pressure at which the amperes are supplied. Again, a name is required for the product. If one ampere of current were supplied at a pressure of one volt, the product might be called one *volt-ampere ;* the word being built up just in the same way as the word foot-pound is made to denote the work done in raising through one foot against the downward gravitation force of one pound. But, though the word *volt-ampere* is sometimes so used to denote the unit of electric power (that is the rate at which electric energy is being supplied), electrical engineers more often give another name to this unit, namely one *watt.* "One watt" denotes by legal definition the amount of electric power which is brought by a current of one ampere flowing under a pressure of one volt. A *Wattmeter* [2] is an instrument which can be directly attached to a circuit to indicate the value in watts of the power that is at any moment being supplied. For the construction of a wattmeter the reader is again referred to ELECTRICAL MEASUREMENT. Let us illustrate the matter further by an example. If in some house there are 85 glow-lamps alight, taking on the average $\frac{1}{4}$ ampere each, and if the pressure at the electric mains is 200 volts, how many watts of power are they taking? The amperes will be $\frac{1}{4}\times 85$, that is, $21\frac{1}{4}$: to find the watts we must multiply the volts by the amperes, namely, multiply 200 by $21\frac{1}{4}$; so that the result is 4,250 watts. That is what a wattmeter would indicate as to the electric supply to those lamps. As the numbers of watts often run into thousands, electricians have adopted the term *kilowatt* to denote 1,000 watts. Hence the power taken by the 85 lamps in question, when all are alight, would be called 4·25 kilowatts.



1. VOLTMETER



2. WATTMETER



3. AMPEREMETER

As the *watt* and the *kilowatt* are units of electric power, they can be compared as to their value with the mechanical unit of power mentioned earlier in this chapter, namely, the horse-power. It can be shown from first principles that one horse-power is equal to 746 watts, or one watt equals $\frac{1}{746}$ of a horse-power. And as one kilowatt is 1,000 watts, it follows that one kilowatt equals 1·3404 horse-power; and that one horse-power equals 0·746 kilowatt. The 85 lamps mentioned will be receiving electrically 5·7 horse-power.

The Kilowatt-hour. If electric power is being supplied the total energy given thereby will be the product of the power and of the time during which the power is supplied. Now, the legal "unit" of electric energy in this country is the *kilowatt-hour.* The electric-lighting companies charge their consumers according to the number of kilowatt-hours of energy they have consumed. They put in meters to measure the amount of consumption, and charge, some *4d.*, some *3d.*, in some cases less, per kilowatt-hour. Suppose, in the case of the 85 lamps used as an example above, taking power at the rate of $4\frac{1}{4}$ kilowatts, the price of the supply was *4d.* per kilowatt hour; then to keep all these 85 lamps alight will cost the consumer $4\times 4\frac{1}{4}$, that is 17 pence per hour. If he has kept them alight on an average three hours a day, then when quarter-day comes his meter will have registered 1,163 kilowatt-hours (or "units"), and at *4d.* per unit his bill for the quarter will be £19 *7s.* *8d.* When electric energy is supplied in bulk to factories from central generating power-houses, the price is usually under *1d.* per unit. Suppose a manufacturer takes 100 amperes at 5,000 volts pressure, that is, takes electric power of 500,000 watts, or 500 kilowatts; and suppose him to use that power for 3,000 hours (*i.e.* an average of 10 hours per day for 300 days) in the year; suppose also that the price charged is $\frac{3}{4}d.$ per unit; then his power will cost him $500\times 3000\times\frac{3}{4}$ = 1,125,000 pence, that is, £4,687 10*s.* per annum. And as he is getting over 670 horse-power, his supply is costing him under £7 a year for each horse-power supplied.

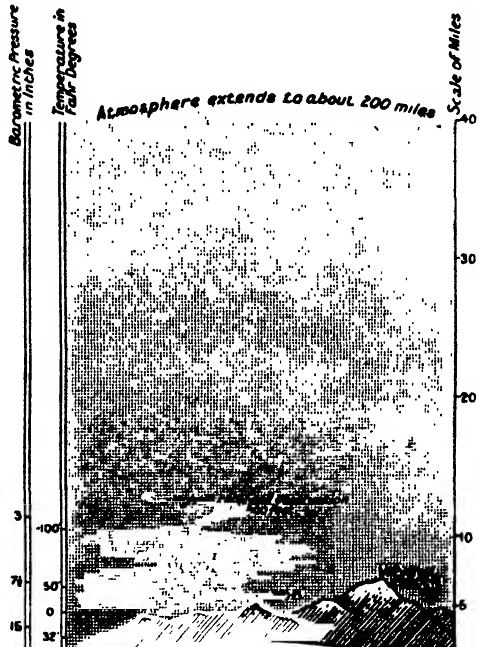
THE CLIMATES OF THE WORLD

The Atmosphere. Rainfall and Its Distribution. Why and When it Rains. The Wind System. Heat and Cold. Temperature of the Air.

By Dr. A. J. HERBERTSON, M.A., and F. D. HERBERTSON, B.A.

BY June 21st the sun is vertically overhead at 23½° N. lat., the *tropic of Cancer*, and its rays reach 23½° further north than they did at the spring equinox, when they just reached the pole. Consequently, within a radius of 23½° round the North Pole—that is, within the *Arctic Circle*—the sun does not drop below the horizon, but is more or less completely visible at midnight. At the tropic itself the sun's rays fall vertically, and more nearly so north of it than at any other part of the year, so that they have their greatest heating power. It is the *midsummer* of the northern hemisphere. In the southern hemisphere, on the other hand, which is at that part of the earth's orbit where it is tilted from the sun, it is *midwinter*. The sun's rays are falling as nearly horizontally as they ever do. Within a radius of 23½° round the South Pole, within the Antarctic circle, they are hardly felt at all. At the South Pole itself it is midnight, the middle of the six months' night which alternates with the six months' day.

After June 21st in the northern hemisphere the sun appears to turn south. The point at which it is vertical at noon begins to recede towards the equator, where the sun is again overhead on September 21st, the *autumn equinox*. Its rays again just reach both poles, making day and night equal. Thereafter the night of the northern hemisphere lengthens and its day shortens, as the sun's rays strike it more and more obliquely. The reverse is true in the southern hemisphere, where the rays are falling more and more vertically, and further and further towards the South Pole. The vertical noon point continues to recede south of the equator till December 21st, when the sun is vertical over the tropic of Capricorn, 23½° S. It is now midsummer in the southern hemisphere, midday at the South Pole, midwinter in the northern hemisphere, and midnight at the North Pole. Then the sun apparently turns north again, and is once more vertical over the equator at the spring equinox, March 21st.



13.

SECTION OF THE ATMOSPHERE

The temperature and the pressure or weight of the atmosphere decrease as the elevation increases.

The student will hardly need to be reminded that this shifting of the point at which the sun is vertical at noon is due to change in the earth's position relatively to the sun, and not to the movement of the sun.

Heat and Light. It is customary to distinguish various *zones*, or *belts*, on the earth's surface according to the amount of light and heat they receive from the sun.

Between the poles and the polar circles are the *frigid zones*, with one long day and one long night at the pole, and elsewhere almost continuous daylight in summer, and almost continuous darkness in winter. There are only two seasons — winter and summer.

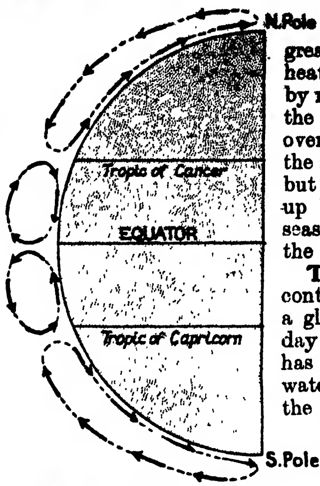
Between the polar circles and the tropics—that is, between the parallels of 66½° and 23½°—are the north and south temperate zones, with long winter nights and long summer days. Besides winter and summer they have the intermediate seasons of spring and autumn.

Between the tropics and the equator are the north and south torrid zones. Here the sun is vertical twice a year, except on the tropics, where it is vertical once. There is no winter.

The belt of greatest heat swings north and south of the equator with the sun, but the equator is always in it. It extends furthest north in the northern summer, when the sun is vertical over the northern tropic, and the northern hemisphere is tilted furthest towards the sun, and furthest south in the southern summer, when the sun is vertical over the southern tropic, and the southern hemisphere is tilted furthest sunwards. The effect of this variation on the distribution of rain and winds is very important, and the fact must be carefully borne in mind. The temperate and frigid belts oscillate similarly.

Of the moving world on which we live we know only the surface. This consists of solid land and liquid water, both visible to sight. Our sense of touch assures us of something more, which we cannot see, but which we feel as breeze or wind. This is the atmosphere, the envelope of air which surrounds the earth, held to it by the force of gravitation, and moving with it on its daily and yearly journey. Without the atmosphere life would be impossible for plant or animal, for neither could breathe.

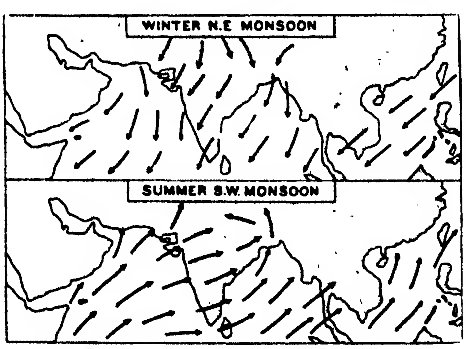
At the surface of the earth, where the force of gravity is most strongly felt, the density of the air is greatest—that is, the particles are most closely packed. As the force of gravity diminishes with the increasing distance from the centre of the earth the atmosphere becomes less and less dense, and at the height of a few thousand feet climbers suffer severely from want of air. [For the composition of air, see CHEMISTRY.] The weight of the envelope of air is measured by the barometer. [See PHYSICS.] It naturally decreases with elevation, and the barometer falls.



14. CIRCULATION OF THE ATMOSPHERE

This diagram shows the theoretical movement of the air between the Equator and the Poles.

Temperature of the Air. Experience tells us that the air is hot in summer and cold in winter. These changes, however, occur only near the earth's surface. The atmosphere allows the rays of light and heat from the sun to pass through it, but is little affected by them, except in the lower, denser layers. About one-third of the solar heat is absorbed by the atmosphere. The remaining two-thirds reach the surface of the earth, from which the layers of air in contact with it receive most of their heat. The temperature of the air is highest close to the earth's surface, and diminishes rapidly away from it. The upper layers of the atmosphere are always cold. Self-recording instruments have been sent up in balloons, and they register up to 100° frost at a height of a few miles [18]. On the top of a high mountain, whether in winter or summer, it is cold unless the sun is shining. The warming surface is reduced by the tapering of the mountain, and the temperature of the surrounding air is therefore but little raised. Nevertheless, it is slightly warmer than air at the same height above a plain, as it is in contact with a small part of the earth's surface.



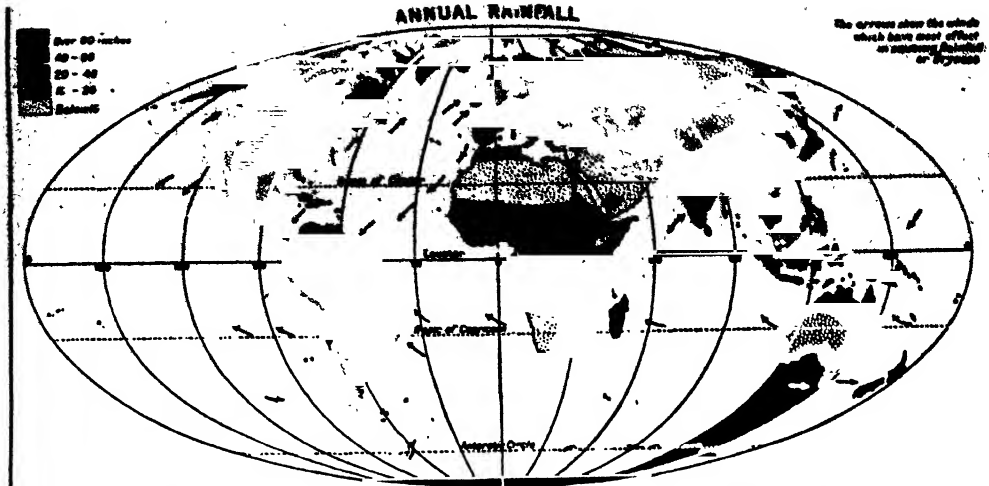
15. THE MONSOONS, OR SEASONAL WINDS OF SOUTHERN ASIA

The earth, then, is always receiving heat and always parting with it. A great part of the heat it receives it radiates back. Land and water differ considerably in their capacity for storing heat. Land absorbs heat more quickly, but the heat does not penetrate far below the surface. Water, though heated more slowly, is heated to a much greater depth by the motion of its heated particles, and it loses heat by radiation much more slowly than the land. The land and the air over it are consequently hotter than the sea and the air over it in summer, but the sea retains more of its stored-up heat on into winter, at which season the air over it is warmer than the air over the land.

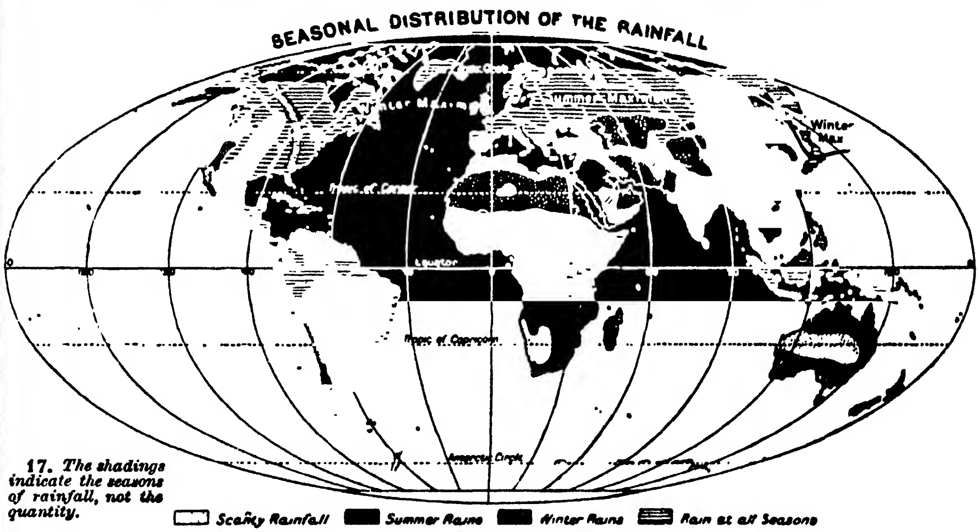
The Cause of Rain. The air contains invisible water vapour. If a glass of water is spilled on a hot day the water quickly dries up. It has been converted by heating into water vapour, and has passed into the atmosphere. The same process takes place on a cold day, but much more slowly. This process of conversion into vapour is called evaporation. The surface layers of water are always evaporating, slowly or quickly, according to the temperature of the air. When air is dry and hot it takes up vapour very quickly and holds a large quantity. When it can hold no more it is said to be saturated, or to have reached the saturation point. This saturation point differs at different temperatures. Air at a high temperature can hold much more water vapour without becoming saturated than air at a low temperature. If the temperature of saturated air is lowered it must part with moisture till it reaches the saturation point of its new temperature. This surplus moisture returns to the liquid form and falls as rain. A familiar illustration may make this clearer. If the hand is placed on a mirror the glass is at once covered with mist. The moisture which was invisible on the hot hand is chilled by the cold glass to the point at which it becomes liquid and visible. This process is called condensation.

The distribution of rain, therefore, depends on air passing from hotter to colder regions—that is, on the wind system of the globe.

The Wind System. We saw that in the equatorial regions there is a hot belt which moves north of the equator when the northern hemisphere is tilted towards the sun, and south of it

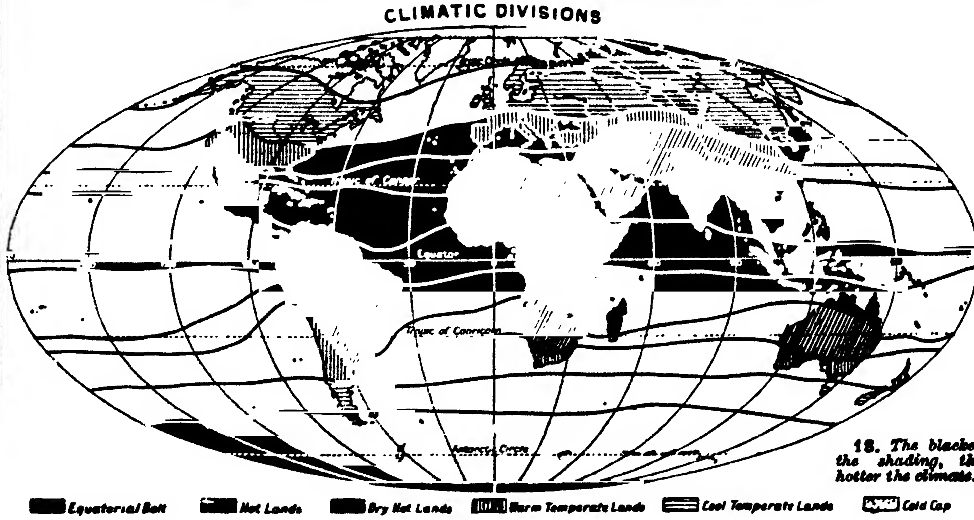


16. RAINFALL ALL OVER THE WORLD. The blacker the shading, the heavier the rainfall



17. *The shadings indicate the seasons of rainfall, not the quantity.*

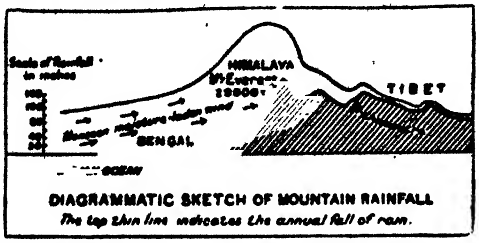
Scanty Rainfall — Summer Rains — Winter Rains — Rain at all Seasons



18. *The blacker the shading, the hotter the climate.*

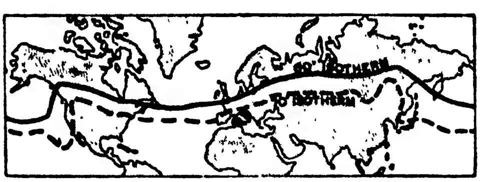
Equatorial Belt — Hot Lands — Dry Hot Lands — Warm Temperate Lands — Cool Temperate Lands — Cold Cap

when the southern hemisphere is similarly tilted. The air over this belt becomes extremely hot. When air is heated its particles expand and require more room, so that a given volume of hot air contains fewer particles than the same volume of colder air, and is consequently lighter. Being lighter, it tends to rise, forming what is called a low-pressure area. Over the heated equatorial regions the hot air is steadily rising, causing calms, which sailors call the doldrums. As it rises air is drawn in below. If the earth were at rest this indraught would be felt as north winds in the northern hemisphere, and as south winds in the southern hemisphere [14]. The earth, however, is rotating, and air flowing towards the equator is deflected to the right in the northern hemisphere and to the left in the southern. The indraught is, consequently, felt as north-easterly or easterly winds in the northern hemisphere, and as south-easterly or easterly winds in the southern.



19. The rainfall on the southern slopes of the Himalaya mountains is very heavy compared with the rainfall which falls on the northern slopes and in Tibet.

These winds blow throughout the year, blowing furthest north in the northern hemisphere in the northern summer, and furthest south in the southern hemisphere in the southern winter. As they can be counted on with certainty they are well called *trade winds*. Columbus owed his discovery of the New World to getting in their track. Meanwhile there is a corresponding movement of the upper layers of air, but in the opposite direction. The ascending air over the equatorial belt passes into regions of the upper air, where it is rapidly cooled. It cannot descend vertically because of the steady upward pressure of the rising air. It therefore streams outwards towards the poles, forming a return current. A proportion of this return current appears to descend almost vertically about lat. 30, forming a belt of high pressure in what are called the horse latitudes, where calms are consequently experienced. From this sub-tropical belt of higher pressure the surface winds flow out not merely as the trade winds towards the equator, but also on the other side towards the poles in temperate latitudes. Here deflection takes place as before—to the right in the northern hemisphere, to the left in the southern; and the outflowing winds consequently blow as south-westerly and westerly winds in the northern hemisphere, and as north-westerly or westerly winds in the southern. We are familiar with these westerly gales in autumn and winter, and they are still more strongly felt in the "roaring forties" of the southern hemisphere—the latitudes south of 40°—where sailors call them the "brave west winds."

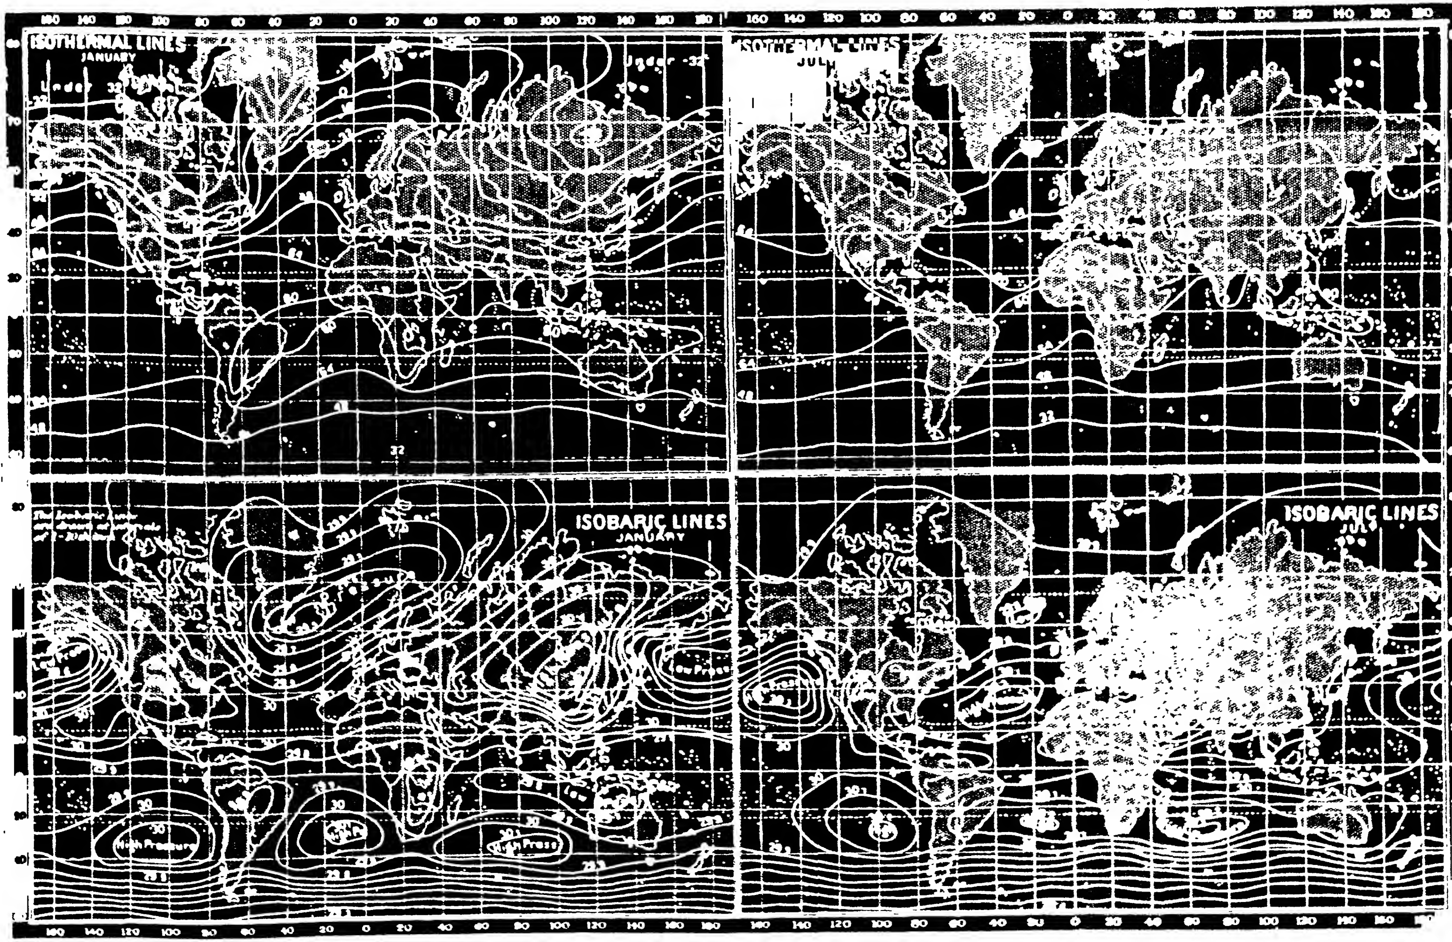


20. SUMMER ISOTHERMS OF 60° AND 70° FAHRENHEIT

The two lines are drawn through all places in the Northern Hemisphere having a mean summer temperature of 60° and 70° Fahrenheit.

Land and Sea Breezes. So far we have considered the wind system without regard to the distribution of sea and land. This, however, causes many local variations. Land, we saw, heats more rapidly by day and cools more rapidly by night than the sea. Consequently, along the margin of sea and land sea breezes tend to blow from the cooler sea by day, and land breezes from the cooler land by night. Exactly similar causes, acting over large areas of sea and land in intertropical regions, produce the seasonal winds known as *monsoons*, of which we hear so much in connection with our Indian possessions [15]. South Asia and North Australia lie north and south respectively of a broad belt of intertropical seas. During the summer the land becomes intensely heated, and the in-blowing winds from the sea acquire great strength. They are deflected to their right in the northern hemisphere, blowing over South-Eastern Asia as the south-west monsoon, and to their left in the southern, blowing over North Australia as the north-west monsoon. During the summer months they displace the north-east and south-east trade winds, which are sometimes called the north-east and south-east monsoons in these regions. Violent storms occur at the change of monsoon.

The Distribution of Rainfall. With few exceptions the heaviest rainfall takes place everywhere in summer, when evaporation is most intense, and the super-heated air is rising into the colder upper layers of the atmosphere. In intertropical regions, except in a belt on either side of the equator, rain falls only at that season, and the year is divided into a wet or summer season, and a dry or winter season. The rain belt moves with the equatorial heat belt, north of the equator in the northern summer, when the north tropical regions have their rainy season, and south of it in the southern summer, when the south tropical regions have their rainy season. Remember that the southern summer is the northern winter. As the equator is always in this hottest belt the equatorial regions have rain at all seasons, but most at the equinoxes. Hence the equatorial regions are sometimes said to



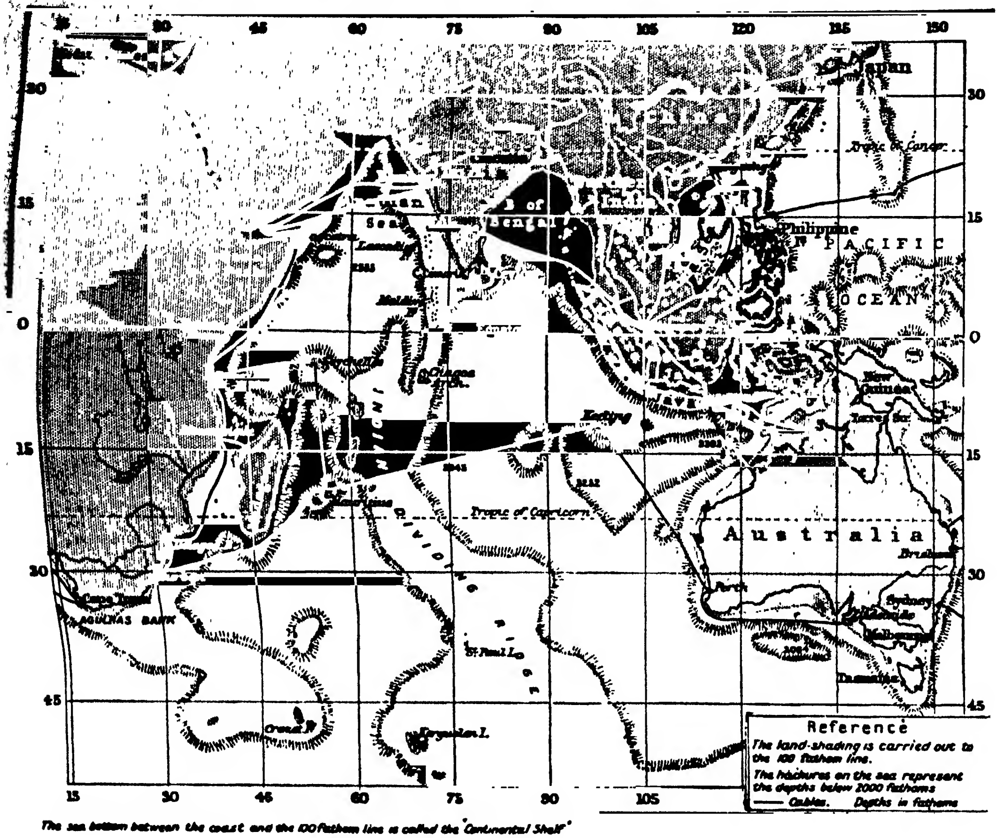
21. HEAT AND WIND PRESSURE: ISOTHERMS AND ISOBARS FOR JANUARY AND JULY

have two wet and two dry seasons. These terms are relative [17].

In the trade wind area there is little rain at any season, for the air is moving from colder to warmer regions, and cannot pick up moisture fast enough to become saturated. If, however, the trade winds strike against mountains which turn them upwards to colder regions of the atmosphere they may bring rain, though not profusely. In the monsoon regions the winds come oversea and are heavily laden with moisture, so that they are rain-bringing winds. The horse latitudes form a high pressure area, where air is descending from higher and colder to lower and warmer regions. Light variable winds prevail, or calms, and little rain falls. Consequently we find on either side of the equator a dry band in the lee of the trade winds, marked in both hemispheres by more or less extensive deserts. As the trade winds extend furthest towards the pole in each hemisphere in the summer of that hemisphere the dry belt in their lee also extends furthest towards the pole in that season, causing dry summers over limited areas. The dry summers of Southern Europe are caused in this way.

Beyond the horse latitudes come the regions where westerly winds blow all the year. They are oversea moisture-laden winds, bringing rain at all seasons. The heaviest rainfall is on the western coasts, especially where these are high. This belt of rainy winds moves nearest the equator in winter, bringing winter rains to the regions which were in the lee of the trade winds in summer. The winter rains of Southern Europe are caused by the southern extension of the westerly winds at that season.

While these are the broad lines on which rain is distributed there are many local variations, depending on various causes, of which the most



The sea bottom between the coast and the 100 fathom line is called the "Continental Shelf"

A Section along the Equator

A Section along 20° South Lat.

23. THE BED OF THE ATLANTIC OCEAN, SHOWING THE CONTINENTAL SHELF

important are the distribution of sea and land and of highlands and lowlands. The greater the distance from the sea, the less in general is the rainfall. Mountainous regions have always a higher rainfall than the surrounding lowlands, as they deflect the winds which strike them up into colder atmospheric layers. There is, however, usually a well-marked difference between the rainfall of their windward and leeward slopes, the latter being much drier. A mountain range lying in the track of winds laden with moisture may receive nearly all that moisture as rain or snow, leaving the winds to pass on as dry winds [19].

Climate. The first rough climatic distinction is into tropical, temperate, and polar climates, corresponding to the torrid, temperate, and frigid zones. This is too general to be of practical use. The causes so often referred to, the varying distribution of sea and land, and of high land and low land, produce many varieties of climate within a limited area. If a mountain situated on the equator is high enough, it will be crowned with perpetual snow, and though it has a tropical climate on its lower slopes, it will have a temperate climate above that, and a polar climate on its highest slopes. In making calculations it is usual to allow for a fall of 1° F. in temperature for a rise of 300 ft. in altitude. This figure is based on numerous observations made simultaneously at various heights on mountains in many parts of the world. The highlands, therefore, are everywhere colder than the lowlands in the same latitude. Look at any good relief map of the world, and you will see what a large proportion of the world has its climate affected in this way.

Equally important in its effect on climate is distance from the sea. We saw that sea-breezes cool the land in summer and warm it in winter—that is, they make the climate of neighbouring lands more uniform or equable. Where they are absent the summers are hotter and drier, and the winters colder and drier. In other words, the range of temperature experienced, varying from very hot in summer to very cold in winter, is great, and the climate is said to be extreme. The greater the land mass, or continent, the further is its interior from the sea, and the more extreme is its climate. Geographers call an extreme climate a continental climate, and one rendered equable by the influence of the sea, an insular or oceanic climate.

Climate, therefore, depends partly on latitude, partly on elevation, and partly on proximity to or distance from the sea.

Isotherms and Isohyets: Their Meaning and Uses. The result of all these causes taken together can only be ascertained by actual observation. For this purpose observation stations and self-recording instruments, which write out their own records, are at work all over the world. They have given us an enormous mass of information about the temperature and rainfall of most places on the earth's surface. The average of these for several consecutive years give us the average temperature or rainfall of any place. Maps are made showing the temperature and rainfall of different regions. A line is drawn on the map, passing, let us say, through all places where the average summer temperature is 60° F. Its shape will be very irregular, for it shows the result of several causes, which are acting in very varying degree. Another line may be drawn through all places with an average summer temperature of 70°. This line will also be very irregular for the same reason. Places with an average summer temperature between 60° and 70° will lie on neither line, but between the two, nearer one or the other, as the case may be [20]. Such lines are called *isotherms*, or *lines of equal heat*. They can be drawn for any temperature, and for any season, month, week, or day of the year required. They give an absolutely correct idea of the actual conditions of temperature produced at any place by all the causes at work, and enable us to compare different places in this respect [21].*

Similar lines, called *isohyets*, or *lines of equal wetness*, are drawn to show the rainfall, measured in inches, experienced by different places in a year, or at any given season. Places through which the isohyet of 40 inches passes receive 40 inches of rain in a year. Places through which the isohyet of 50 inches passes receive 50 inches of rain, and so on [16]. The maps which show how this is distributed in the various months are very important. There are many purposes for which we want to know if rain falls regularly through the year, or if one month is very wet and all the others very dry.

There is still another set of climatic maps, constructed to show the distribution of high and low pressure, which is indicated by *isobars*, or lines of equal pressure.

When we know the winter and summer temperatures of a place, the amount of rain it receives, and how this is distributed throughout the year, and the barometrical conditions, we know its climate, and can judge if it is fit for the home of man, and what sort of occupations can be carried on there with a reasonable chance of success. No atlas should be bought which does not contain maps showing the isotherms and isohyets, for these represent the data by which man has to be guided in his work in the world.

Climate Divisions. No hard-and-fast line can be drawn between climatic regions, for the transition from one to the other is extremely gradual. We may distinguish:

1. The equatorial regions, hot and wet at all seasons, with two wetter periods at the equinoxes.

2. The hot lands with a summer rainy season, including the monsoon lands in the trade wind area.

3. The hot dry lands, in the track of the trade

* Temperature observations are generally reduced to sea-level—that is, an observation has 1° F. added for every 300 ft. One of 48° F. at a station 1200 ft. high becomes 52° F. when reduced to sea-level.

POETRY: ITS ORIGIN, PURPOSE & VARIETIES

An Exposition of the Characteristics of Poetry, its Difference from Prose, and a Brief Guide to the Common Forms of English Verse

By J. A. HAMMERTON

IN a frankly utilitarian survey no one will look for anything so temerarious as an attempt to cover within the space of four pages a subject on which a whole library of learned works has been written. All that can be contemplated is the barest outline of some general principles with which we should be familiar before we set ourselves with any seriousness to the study of poetry.

Poetry is the first, as it is the highest, expression of the human mind. We may reasonably assume that there were poets long before alphabets; and when we hear anyone say "I cannot read poetry," we are to consider that person out of harmony with nature, as surely as the man who is deaf and dumb or blind, though he may never suspect his great infirmity. Of all forms of human expression, poetry is the most natural and direct; and it ought to be the readiest of response. Indeed, it is so. Despite all ignorant or flippant talk of poetry, the heart of a people always responds to it in moments of exaltation, and even those who confess they are unable to "read" poetry cannot escape its influence; since there is in the nature of mankind the stuff of poetry, which must at times manifest itself in all our lives.

What Poetry is. But what we really mean by poetry is not merely the ingenious arrangement of words and phrases in o lines beginning with capital letters and ending with words of similar sound; it is one of the elemental things of Nature, like electricity, and perhaps, in its deeper significance, no better understood. The Æolian harp may be taken as an illustration. This stringed instrument of the ancients, placed where the wind could blow upon it, gave forth sweet sounds. Man made the instrument, but Nature produced the music; neither acted alone —it was a relation of *inter*dependence. So with poetry: it is not merely Homer nor Dante, not Shakespeare nor Milton, who plays upon our feelings and our senses when we read his poems. He supplies the magic, emotion-fraught words, and we the listening hearts; but it is the soul of all remembered emotions and aspirations in each one of us—the very "rhythm of life," as one great critic calls it—that attunes these words to the needs and possibilities of each individual nature, and thus *applies* "poetry."

The Poetic Power of Words. The poet in this sense is the maker of the Æolian harp; Nature (as the winds and stirrings of our emotions) the player, and we the hearers, more or less acute, who catch or miss the sounds, according to our varying susceptibilities. Take the word "home" as an example. In no two minds does this monosyllable of four letters awaken *absolutely similar* ideas: "The old home," "home, sweet home," "home is home"— how colourless and inexpressive the word and these phrases are when coldly analysed; yet how they may each stir the pulses and quicken the memory when met with in poetry, and even in prose! And why? Simply because we associate our personal joys and sorrows with this index word and its connotations, and so become in a manner joint artificers with the poet. Hence the great poet is he who most successfully awakens in us, not only his, but *our own* thoughts and memories, by using the most expressive language in voicing his own thoughts and emotions. From this we shall rightly be held as esteeming emotional language essential to poetry. There is wonderful power in mere words. Tennyson all his life was affected by the words "Far, far away." As a boy they moved him poignantly. Who would ever have quoted Keats's famous verse:

"A thing of beauty is a joy for ever,"

if he had left it, as originally written, "a continual joy"?

The Beginning of Poetry. Although this helps us only a very little way towards the understanding of poetry, it does not seem too much to assert that by men first discovering the power to utter words potent to awaken responsive emotions in their fellows— having fitted first of all their own emotions, *of which the words were part and parcel*—began that intercommunion of souls which, in the course of ages, creating for itself certain conventions of form, shaped itself finally into what we know as poetry. In the earliest recorded history of our own land the bard had his place in the social scheme; and to a far greater degree than in our own time was the national need of poetical expression recognised, the poet articulating what his fellows felt but dimly and were quite unable to body forth. The bard was then, as now, both historian and prophet, interpreting his age to itself and to posterity.

These old Gaelic singers, in the early centuries of the Christian era, were often warriors as well; but many of them were more akin in their social status to the modern professional men of letters than any poets or historians in the intervening ages. The need of singers to arouse enthusiasm for battle, to celebrate victories, to mourn over defeats and commemorate the fallen heroes, was as great in those rude days of Fionn, Oisin, and Merlin as—to use a very homely illustration— the need of the political pamphleteer and leader-writer in modern electoral times; but many times more dignified, more in tune with Nature. Thus, in our own land, as twelve

hundred years earlier in Greece, when Homer celebrated the Trojan war in the first great poem of imperishable genius, the beginning of poetry as a literary expression was associated with "arms and the man"; but in the still more ancient "poetical books" of the Bible we have it associated with the divine aspirations of the soul; and the real beginning of English poetry was also religious, much of the poetic energy of our race, first expressed by Caedmon in the seventh century, being informed by a deep devotional spirit which has ever remained a characteristic of English poetry.

We must not at this stage be tempted further into the history of poetry, since in succeeding parts of our study we shall pursue the historical method by treating of poetry from Chaucer to our own time, and only those of us who are wishful to specialise in this branch of learning need turn our attention very seriously to the writings of William Langland, Laurence Minot, and the lesser poets who came between Caedmon (d. about 680) and Chaucer (b. about 1340, d. 1400).

The Criticism of Poetry. What will be of immediate practical use to us, indispensable indeed to the intelligent reading of any poetry, is a working knowledge of its constituents and varieties. This may be thought a wrong phrase to employ, smacking as it does of the laboratory; but while it is tolerably certain that the greatest of poets wrote almost unconscious of art, their exalted thoughts taking on an exalted and inevitable rhythm in perfect harmony with the canons of art, because *above* all art and of a piece with that elemental voice of Nature expressed in the well-known line from the Book of Job, "When the morning stars sang together"—because of this, we are open to believe that it is as possible to establish a scientific analysis as of any other energy of Nature. But it would be difficult to select a more controversial subject than the "scientific" criticism of poetry. This we may venture, however, to set down: that, as everything in life may be submitted to scientific analysis, there is no fatal reason why poetry should not also be subjected to such analysis. At any rate, none of the varying criteria whereby men have attempted to define and judge the poet's art has quite met the case, and the criticism of poetry is to-day about as difficult to define as poetry itself. For criticism has changed as persistently as art in standards of taste, else why in one age do we find artists denounced by their contemporaries who are acclaimed by posterity, and others admired by their contemporaries who are swept into oblivion by those who come after? To apply rigidly the standards of one age to the judgment of art produced in another is proved by certain historical examples to be futile. It is the glory of Aristotle's system of criticism that so much of it may still be applied to modern art; but criticism generally works out thus: after we have examined and accepted so many principles, the great new artist comes along and upsets our comfortable theories. In our own time Walt Whitman offers a good instance of this.

One thing that does seem to be within the range of even timorous assertion is, that rhythm and verse-form are the essential characteristics of poetry. Yet many eminent critics, Carlyle among them, have contended that prose can possess all the necessary qualities of poetry. It is generally agreed, however, that both poetry and prose have their "rhythm," while metre is the added quality of poetry, and this metre is not mere ornament, but of the very fabric of the thought itself. By which we mean that the emotions or thought-material of the poet whom we loosely call "inspired" have an inherent, rhythmic, metrical quality, which is not the mere literary decoration of the artist, but the very voice of Nature herself. Rhyme, on the other hand, is purely ornamental, and a non-essential of poetry, though so scholarly a critic as Dr. Johnson had a great distaste for blank verse, and an author of our own day, who enjoys considerable vogue, has had the fortitude to assert that a cat might be taught to write blank verse. This only illustrates how critics may differ, and must be our excuse for refusing, even if space permitted, to enlarge upon the controversial side of poetical criticism.

The Difference of Prose and Poetry. Let us, however, be bold enough to borrow from Mr. Mark H. Liddell's ingenious work, "An Introduction to the Study of Poetry" (with much of which we are unable fully to agree), what may be submitted as a rough working test of the fundamentals of poetry, before we proceed to note its metrical varieties. Mr. Liddell takes this passage from *Macbeth*, wherewith to test the qualities that render poetry distinct from prose:

> "Duncan is in his grave;
> After life's fitful fever he sleeps well;
> Treason has done his worst: nor steel, nor poison,
> Malice domestic, foreign levy, nothing,
> Can touch him further."

This we will presume to be poetry, despite the vapourings of Mr. Bernard Shaw as to his, or his cat's, ability—we are not quite sure which—to write like that. Mr. Liddell re-casts the passage in what may be called literary or rhythmic prose:

> "Duncan lies in his grave. Life, that racks my soul with succeeding ague-fits of fear, for him is over and he sleeps in peace beyond the reach of treason. The assassin's steel or poisoned cup, secretly fomented strife at home, treacherously assisted hostility from abroad—none of these can harm him now."

He next reduces it (though not quite successfully, we think) to "a bald statement of facts," as follows:

> "The life of Duncan is extinct, and he is no longer affected by the personal vicissitudes and dangers of government, such as assassination, treason, rebellion, and foreign invasion, which produce this anxiety in my mind."

Mr. Liddell then proceeds to examine these three forms of the same thought. The last (which, for this experiment, may be regarded as the first form of the thought) is, he considers, so plain and dispassionate a statement of the fact that it would hardly awaken any strong emotions in the breast of anyone save Macbeth himself. It is *not poetry*. But the second is framed in words charged with emotional qualities, which must necessarily affect the feelings of all readers, though not invariably touching them to the same issues. This added quality in the second stage we are to denote as "Human Interest," and this Mr. Liddell very rightly considers the determining element of literature: "that common and general interest, which its thought possesses for all men who think, regardless of those peculiar attitudes toward life that arise from peculiar pursuits and occupations"—a doctor, for instance, not looking on death in the same way as a non-medical man or woman, nor an undertaker finding in the word "grave" the same emotions as one to whom the surroundings of the tomb are less familiar. Still, the second stage is *not* recognisable as a *poetic form*.

Matter and Form. But, in the third stage (or, properly, the first Shakespearian form), the thought material is, both in substance and in form, in warp and woof, as it were, poetical; or at least what only a mountebank critic or a blockhead would refuse to regard as poetry. This may be explained on several grounds, but the change is due chiefly to the regular rhythm and the metrical movement of the verse, which punctuate the thought; marking off its different "impulses," its "units," and projecting vividly into the mind of the reader what was in the mind of Macbeth; not—let us note—merely what was in the mind of Shakespeare; for this is an instance of what Mr. Theodore Watts-Dunton calls "absolute vision," the vision of dramatic poetry. The thought and expression here seem to us *one and indivisible*, which may prove even more than Mr. Liddell set out to prove: that in the two forms into which he altered the passage, he must have taken away more than expression, so that his "bald statement" of the fact was really not a statement of the fact at all, the *real full fact* existing only first and last in the thought *and* form of Shakespeare's verses. We might advance our point by giving a simple illustration. Edgar Allan Poe wrote two of the finest lines in poetry:

> "To the glory that was Greece,
> And the grandeur that was Rome."

But he had written them previously thus:

> "To the beauty of fair Greece,
> And the grandeur of old Rome."

In changing the words, he not only charged the lines with a grander music, but vitally altered, expanded and improved the thought.

But this is a point that need not detain us. Enough that we have got, roughly at least, a hint of the difference between literary prose and poetry; and we fear to venture further along "scientific" lines, remembering Stevenson's unhappy example in that direction.

The Dividing Line in Poetry. There is one great dividing line in poetry itself which must be understood at the beginning, and this is nowhere so clearly defined as by Mr. Watts-Dunton in his famous article on "Poetry" in the "Encyclopædia Britannica" (which no student of literature should omit to read). He there says that "of poetic imagination there are two distinct kinds: (1) the kind of poetic imagination seen at its highest in Æschylus, Sophocles, Shakespeare, and Homer; and (2) the kind of poetic imagination seen at its highest in Pindar, Dante, and Milton, or else in Sappho, Heine, and Shelley. The former, being in its highest dramatic exercise unconditioned by the personal or lyrical influence of the poet, might perhaps be called absolute dramatic vision; the latter, being more or less conditioned by the personal or lyrical impulse of the poet, might be called relative dramatic vision." Let us bear this in mind, as it will greatly help us to appreciate poetical values.

Rhythm. By this term is meant the *regular recurrence* of certain fixed sound-relations determined by time and stress, or by quantity and accent. Attempts have been made to establish the measurement of English verse on the principle of syllables and pauses, as with French poetry; and this, though unsuccessful as a whole system, has modified the classical rhythm of long and short syllables to the modern rhythm of accented and unaccented syllables. Neither is a perfect measure applied to English verse, but we must work with the latter as best we may, using terms of classical prosody not quite suited to English poetry. When rhythm is measured by "feet," it becomes metre.

Metre. This is the definite measurement of poetry by feet and verse of different lengths, a verse or line containing several feet. Thus we have monometer, dimeter, trimeter, pentameter, hexameter, etc., or, in simpler language, verses of one, two, three, four, five, and six feet.

Feet. There are in English poetry—to which we must confine ourselves in the present study—four principle feet, known as the anapæst, the dactyl, the iambus, and the trochee. The *Anapæstic* foot consists of two short or unaccented syllables, and one long or accented syllable thus:

> "Thĕ Ăssy̆r|ĭan cāme dōwn | lĭke ă wōlf | ŏn thĕ fōld,
> Ănd hĭs cō|hōrts wĕre glēam|ĭng wĭth pūr|plĕ ănd gōld."

There are four feet in each of these verses, which are thus known as anapæstic tetrameters. The *Dactyl* is the reverse of the anapæst, consisting of one long and two short syllables:

> "Cōme tŏ mĕ, | dēarĕst, Ĭ'm | lōnely̆ wĭth | *out thee.*"

The final foot of this verse, which consists of the two syllables we have italicised, is not a dactyl, but a spondee, or a foot of two equal

accents, with which a dactylic verse usually ends. The *Iambus* is by far the most common feature of English poetry, and is the measure of our heroic verse. It is an unaccented syllable followed by an accented one, as:

"Uneăsily̆ liēs | thĕ hēad | thăt wēars | ă crōwn."

Lines of five such feet, if they rhyme with others, are known as "heroic verse"; and if unrhymed they form "blank verse." It is in this blank verse that the plays of Shakespeare and the poems of Milton are written. The *Trochee*, so far as English poetry is concerned, is, practically speaking, the opposite of the *iambus*, being a foot in which an accented syllable precedes an unaccented one:

"Līves ŏf | grēat mĕn | āll rĕ | mīnd ŭs," etc.

The term is also used in connection with the pause or cæsura, a trochaic cæsura being a pause between the two short accents of the dactyl in the second, third or fourth foot of the hexameter; thus there would be a trochaic cæsura after "dearest" in the line,

"Come to me, dearest | I'm lonely without thee,"

the pause indicating a new thought-impulse.

Rhyme. This is a totally different thing from "rhythm," and is quite unnecessary to poetry. It is, we have heard, only an ornament, but for that reason is identified with certain kinds of verse whose æsthetic beauty lies largely in their form. It is chiefly associated with lyric poetry, or the poetry of personal emotion, which comes under the classification of "relative vision." The *sonnet*, the *elegy*, the *ode*, the *psalm*, and the *hymn* are all included in lyric poetry. The meaning of the word "rhyme" is so apparent that it need not be illustrated, but beginners should know that wherever a poet ends a verse with a rhyme-word in which the accent falls on the second last syllable, there must be an extra syllable in that line, and in its companion. Thus, in stanzas of iambic pentameters it is often necessary to introduce lines in which eleven syllables occur. But in blank verse only the one line ending with a word accentuated on the penultimate syllable requires the extra syllable. Thus Shakespeare writes:

"Tell him this tale; and from the mouth of England
Add thus much more,—That no Italian priest," etc.,—

the one line of eleven and the other of ten syllables. While Dryden, in his satire "Absalom and Achitophel," which is composed in the heroic couplet, writes:

"Praising and railing were his usual themes,
And both, to show his judgment, in extremes.
So over violent, or so over civil,
That every man with him was god or devil."

The first couplet has ten and the second eleven syllables in each line, as the accent falls on *civ*-il and *dev*-il. (It will also be noted that the poet meant "violent" to be a word of two syllables only.) Such double rhymes are called also "feminine rhymes," and there is the "feminine cæsura," or pause between two unaccented syllables:

"I stood in Venice | on the Bridge of Sighs."

A masculine cæsura is a pause occurring between two accented syllables. The pause is usually required near the middle of a verse, but varies according to the incidence of stress and accent. The only further remark that may be made in respect to rhyme is that when the ear is conscious of some unnatural or fantastic rhyme, a false or strained accent in the verse, the poet has failed, as the form should not interfere with the even flow of the thought: the manner should not distract our attention from the matter. In poets of the past allowance has to be made for the constantly changing fashions of accentuation.

Space does not allow of our entering further into detailed explanation of the varieties of poetic form, which, as we proceed with our studies, will have to be examined; but we may now claim, even if we have soporised somewhat with the "scientific" criticism of verse and with modern prosody, to possess some knowledge which we can immediately apply in our reading of poetry.

EXERCISE IN ENGLISH METRE

Define the varieties of verse illustrated in the following quotations, and mark each accor… 'y:

1.

For the earth he drew a straight line,
For the sky a bow above it,
White the space between for daytime,
Filled with little stars for night-time.

2.

This royal throne of kings, this scepter'd isle,
This earth of majesty, this seat of Mars,
This other Eden, demi-paradise;
. . . . .
This blessed plot, this earth, this realm, this England.

3.

Man is a ship that sails with adverse winds,
And has no haven till he land at death.

4.

Henry, too, hath here his part:
At the gentle Seymour's side,
With his best-beloved bride,
Cold and quiet here are laid
The ashes of that fiery heart.

5.

State what is wrong with this line from Milton:

"Void of all succour and needful comfort."

6.

Farewell to others, but never we part,
Heir to my royalty, son of my heart.
Bright is the diadem, boundless the sway,
Or kingly the death that awaits us to-day.

7.

Like the leaves of the forest when summer is green,
That host with their banners at sunset were seen:
Like the leaves of the forest when autumn hath blown,
That host on the morrow lay wither'd and strown.

BUILDING

2

FIRST ESSENTIALS IN BUILDING OPERATIONS

A Consideration of the Leading Operations incidental to the Beginning of any Building Undertaking

By Professor ELSEY SMITH

THE various operations incidental to the working up materials into complete structures are varied and complicated. In the simplest building workmen belonging to two or three different trades are employed, and in most buildings the majority of trades are represented. Separate sets of workmen are employed, as a rule, in each of the different trades. They are roughly divided into unskilled workmen or labourers and skilled workmen, those who have received a training or apprenticeship in some craft requiring manual dexterity. The unions regulating the different trades lay down rules limiting the class of work that the tradesman in each trade may perform, and a skilled artisan may not, as a rule, perform labourer's duties.

The Workmen. The labourer performs most of the heavy work of building operations, such as unloading materials and supplying them to the skilled workmen, and are told off for this purpose. They also execute excavating and concreting. Superior labourers are specially employed as drain layers and for erecting and altering scaffolds. The latter are termed scaffolders.

The tradesmen who are skilled artisans comprise the bricklayer, who also sets terra-cotta work and faience; the pavior, including mosaic worker; the mason, including the slate and marble mason; the carpenter; the founder and smith, including the structural iron and steel worker; the gasfitter; the slater or tiler; the external plumber; and the zinc worker and coppersmith. In some of these trades, which are employed in erecting and covering in the actual structural work or "carcase" of a building, part of the work may be prepared elsewhere; but in each a great part of the work is necessarily executed on the spot. The other principal trades are those of the plasterer; the joiner, who usually also supplies and fixes the ironmongery; the electrician for lighting, bells, and sometimes power; the internal plumber, who provides hot and cold water supply, and various sanitary fittings; the painter and decorator; the glazier and the paperhanger; the services of the heating and ventilating engineer, and of the electrician, are also often included. In the case of the joiner, the work is mostly prepared at the builder's yard and brought to the building practically ready for fixing, but the work in other finishing trades is largely carried out on the spot. Fireproof work, heating and ventilation, though special work, is usually carried out by one or more of the above tradesmen under special supervision.

The Foreman. A *General Foreman* is appointed by the builder, and his duties are numerous; not the least important is that of organising the work of the different tradesmen so that they may follow each other without interruption and, if possible, without reducing, even temporarily, the number of men employed. He is also responsible for the ordering of materials from the builder's yard, and for the quality of the work. He makes to the builder a return of the money earned weekly by each workman, and of all work executed, materials used and required, and of time and material expended on day work as distinct from contract work. In a large business there is often a walking foreman, who visits and generally supervises all works in progress. On a large building each of the important trades has also a foreman whose duties are less wide, being confined to the work in his particular trade.

The *Clerk of Works*, when one is employed, is appointed by the architect as his representative on the building during its erection, and it is his duty to examine all materials, to satisfy himself that they are as specified, to oversee the work generally, to see that it is sound, well put together, and executed in accordance with the drawings and specification. He should render a weekly report to the architect, detailing the state of the work, the materials received, the drawings received and required, the number of workmen in each trade, and the state of the weather.

Drawings. Before the erection of any building a set of drawings, generally to a scale of ⅛ inch or ¼ inch to the foot, and showing the work to be executed, is prepared. The drawings should show plans of every floor or story, of the foundations and roof, and of the site and drainage: elevations of every side of the building, and two or more sectional plans of different parts of the building, the number depending on its size and complication.

These are the *General Drawings*, and are supplied to the builder by the architect; they are drawn to scale and should indicate, in as much detail as possible, all the work to be executed as far as it can be foreseen. They form the most important source of information that the builder has regarding the disposition of the building. Copies of all of them, or of the most important, are submitted to the local authorities before work is begun. This is required so that the surveyor to the local body may ascertain that the work is designed in accordance with any bye-laws or regulations affecting the conditions of building in the particular district. Both the foreman and clerk of works should have a complete set of general drawings on the works in addition to the set given to the builder.

Specification. The builder is also furnished by the architect with a written description of the work to be executed. This is termed

work at once, but there may possibly be trees to fell or shrubs to remove. Where the site has been previously built upon, existing buildings must be removed; if they are small, this may be left to the builder, who pulls them down and removes the materials, excepting any permitted to be re-used, giving a credit for them; but in the case of large buildings a *Housebreaker* is called in to take down the old buildings and remove the materials before possession of the site is given. In the case of alteration to existing buildings the old work may have to be temporarily shored, and this work will be dealt with later in the Course. Temporary screens or partitions may also be found necessary, if the old building is to be used for residential or business purposes during the alterations, or if the builder is not to have complete possession of it. Such screens are lightly framed, covered with boarding or canvas and papered to keep dust from entering; if they are required to keep out weather a tarpaulin should be placed over the screen when it is fixed.

When an alteration involves the removal of an existing roof temporarily, a frame is formed above it with scaffold poles and boards laid at short intervals and the whole is covered with tarpaulins, which should be arranged with a slight fall in one direction to throw off any water, and be at such a height as to allow of the required work—it may be the addition of a story to the building—being carried out under it.

Setting Out. The plan of the building must be carefully set out upon the ground; the ground plan should be fully dimensioned for this purpose. If dimensions are not figured they must be taken off with a scale. In town sites the exact position is usually fixed by contiguous buildings, but on an open site the position may only be finally settled after more than one trial, so that the best aspect and point of view may be secured. With large and complicated buildings the setting out, especially if the plan is irregular, may be a somewhat difficult process, and may be facilitated by the use of a theodolite [See SURVEYING], for fixing the main lines and angles.

The builder is required to set out the building, and may be held liable for mistakes, and accuracy is very essential; it is of great importance to see that all right angles are truly square and all other angles correctly set out. When the outline is fixed the thickness of the main walls and the projection of the footings and concrete require to be marked. This is usually done with boards fixed horizontally to two stakes driven into the ground in line with the wall to be defined and placed so far beyond its ends as not to be interfered with by the excavation of the site. On each board cuts are made on the upper edge marking the inner and outer face of the wall and the footings, and concrete on each side may be marked with similar cuts or by nails. A line, strained between the two boards, will allow of a plummet being dropped at any point along the line of the wall or its foundations, whereby its exact position may be fixed.

Levels. It is further necessary to fix the level of the ground floor, or of some other well-defined level in the building; this also should be marked on some adjacent object that will not be interfered with, and from which a horizontal line can be levelled across to the site by means of a dumpy level [See SURVEYING], or by a series of stakes the tops of which are accurately levelled with a straight-edge and carpenter's level.

From the fixed level, termed a datum, measurements can be taken defining the depth of the foundations and the heights of various parts of the building, where they are not uniform; long rods, called *story rods*, are set out on which the level of the upper floors, windows and other features are marked and by which the accuracy of the work as it proceeds can be checked. The datum level should be shown upon the drawings and all levels given in relation to it; the most convenient datum, as a rule, is the level of the principal floor above the ground at the entrance, or some real or imaginary line above or below it. When a fixed point on the ordnance survey is near a building, it may be very conveniently taken as a datum, and the level of the principal floor fixed in relation to it.

Additions and Alterations. Changes are frequently required in existing buildings, and are in many cases somewhat troublesome. Difficulties in levels and planning have often to be overcome so as to provide an addition that shall, when completed, form an integral working part of the original structure without awkward features or changes of level in the floors.

It frequently happens that the work of alteration is more troublesome to the builder than would be the erection of an entirely new structure, and the circumstances affecting the execution of the work require very careful consideration in arriving at an estimate of price. Any difficulties should be referred to in the specification where one is provided. A few of those that frequently arise in such cases may be discussed. The special provision of screens and protection has been already mentioned. These are easily provided for, but the effect of some working conditions can only be estimated with a very wide margin for accuracy. One of the most important limitations is often that of working space for storing materials, sheds, &c., the result being that materials must be delivered in small quantities and at short intervals, requiring much foresight on the foreman's part. Another very serious factor with some alterations is the necessity that the occupier should keep the business in full swing during alterations. In the case of a shop—*e.g.*, protection for the goods and access for the public may have to be maintained, or, in the case of a factory or works, communication between different parts may be necessary notwithstanding that the building operations may come between them. Also there is often increased expense in executing new work to correspond with existing work; this is especially the case in matching the colour of brickwork and in dealing with the details of finishings.

A SHORT DICTIONARY OF BUILDING CONSTRUCTION

Terms peculiar to individual trades are dealt with in their respective departments.

ABUTMENT—The solid part of a pier from which an arch springs directly.

Ancient light—An opening for the admission of light and air that has, by prescription, obtained a legal right to such easement in perpetuity.

Angle of repose—The natural angle at which any given material will remain at rest.

Annulet—A fillet or band circular on plan.

Applied ornament—Ornament attached to the surface, not worked on the solid.

Area—An enclosed court or yard. A sunk space arranged for lighting or for access to a floor below the ground level.

Arris—The line formed at an exterior angle by two intersecting surfaces.

Aspect—The quarter of the heavens which any front or opening of a building faces.

Astragal—A small moulding semicircular in profile.

Attend upon—A term indicating the assistance to be given to each tradesman by other trades.

Attic story—A story formed wholly or partly in a roof.

BALCONETTE—A small balcony.

Barrel roof—A roof of which the soffit is semi-cylindrical.

Base—The foot or lowest portion of any part of a building.

Basement—The story of a building below the principal or ground floor.

Bay—The subdivision longitudinally of a building by piers, arches, girders, etc.

Beam—A piece of timber or iron placed horizontally—generally over a void.

Beam compass—An instrument for drawing large circles composed of a lath and adjustable slides carrying the point and pen and pencil.

Bearing—The area of support to the end of a joist or beam. Also used to denote the clear distance intervening between such points.

Bed—The horizontal surface on which stones, bricks, and other substances used in building rest. In arches the bearing surface on each side of a voussoir.

Bed mould—A moulding immediately below and apparently supporting an overhanging surface.

Bevel—The slope formed by cutting off a right-angled arris by a plane intersecting both original planes.

Block plan—A plan showing a site on which only the outline of buildings is indicated.

Boning—The act of making or judging a plane surface or line by the eye.

Break—The recess or projection of one piece of work behind or in front of the remainder.

Bullnose—A rounded junction between two surfaces enclosing an angle.

Buttress—A mass of masonry or brickwork so disposed as to counteract the thrust exerted by an arch or vault.

CAMBER—A slight convexity to counteract deflection due to load.

Camp-sheeting—A timber retaining-wall to prevent erosion in rivers and canals.

Cant—Any part of a structure formed at an angle other than a right angle.

Cantilever—A beam, bearer, or girder, one end of which is free and the other fixed.

Cap—The crowning member of a pier or column.

Capping—A moulding or group of mouldings on the top of a dado, screen, or gate.

Carcase—The structure of a building before finishings are added.

Castellated—Terminated with battlements.

Catch-pit—A pit formed to collect fluid or solid matter.

Caulking—The stopping of open joints.

Chamfer—See Bevel.

Channel—A long sinking formed in the ground or on the surface of any material.

Chisel-pointed—With a flat, broad point.

Cinquefoil—A form of enrichment having five cusps.

Circle on Circle Work—Work circular in elevation as well as on plan.

Clearstory or **Clerestorey**—A range of windows placed high up in a hall or church.

Clear, In the—The net distance between any two points or surfaces.

Clear span—See **Bearing**.

Clerk of Works—An individual appointed to superintend building operations on behalf of the architect.

Coffer—A sunk panel in a ceiling or soffit.

Coin or **Quoin**—The external angle formed by the junction of two walls.

Collar—A ring of metal or other material placed round any object.

Colonnade—A range of columns.

Column—A vertical circular support.

Concavity—The hollow side of a curved line or other object.

Concentric—Circular figures or portions of circles struck from a common centre.

Conduit—A term applied to a channel or pipe used for the conveyance of fluids.

Console—An ornamental bracket used to give real or apparent support to a cornice or other feature.

Convex—The swelling side of a curved line or other object.

Contrary flexure—A curve, part of which is convex and part concave.

Corbel—A projection from a wall to carry any overhanging portion.

Core—The interior, heart, or centre of any object.

Cornice—A group of mouldings crowning a wall or other surface.

Corona—A broad vertical face in a cornice with an overhanging soffit.

Countersinking—A sinking formed in timber or other material to receive the head of a screw or bolt that it may be flush with or below the surface.

Cove—A large hollow moulding generally formed in the cornice of a ceiling.

Crank—A rigid arm fixed at the end of a shaft perpendicular to its axis.

Cresting—An ornamental finishing to a ridge or parapet.

Crib—A stable rack.

Crown—The highest part of an arch or vault.

Crushing Load—The load under which any material loses its power of cohesion.

Culvert—A circular underground channel for conveying fluid.

Cupola—A spherical roof or dome.

Cusps—The points between the foils of a foliated arch.

DADO—The central feature of the pedestal of a column, or a deep band, usually with base and capping at the base of a wall.

Dead load—A permanent load, one which does not move.

Dead shore—A vertical timber strut receiving a dead load only.

Dentils—Square blocks carved out of a projecting fillet.

Detrusion—An outward thrust tending to separate one body from another. A shearing strain acting parallel to the fibres of a material.

Die—Another term for dado. Also a mould from which objects in relief may be struck.

Dome—A convex roof over a circular or polygonal building.

Dominant tenement—In the case of an easement the tenement to which the privilege belongs.

Dormer—A window placed on the inclined plane of a roof the front of which is vertical.

Dressings—Brickwork, terra-cotta or masonry finishings of a superior quality introduced into rougher walling.

Drum—A vertical, circular, or polygonal wall carrying a cupola or the blocks of material composing the shaft of a column.

EAVES—The lowest edges of the inclined sides of a roof projecting beyond the walls.

Elastic limit of any material—The greatest strain that does not produce a permanent set.

Elevation—A geometrical projection representing the outer surface of an object on a perpendicular plane.

Embossing—The raising or forming of any form or design above the surrounding surface.

Engraving—The cutting in or sinking of any form or design below the surrounding surface.

Enriched mouldings are those whose profile is treated with ornament.

Entering angle—The internal angle formed by the intersection of adjacent surfaces.

Entresol—A room formed above another in the general height of a lofty story.

Estimate—The computed cost of any work.

FABRIC—A term applied to the structural portions of buildings.

Façade—The face or front of any building.

False bearing—A column or wall bearing on the unsupported part of a girder.

Fan—An apparatus for mechanically changing or moving air. A hoarding projecting outwards during pulling down.

Fatigue of material—The failure of material under a recurring load which produces a stress exceeding its elastic limit.

Feather edge—A term applied to any thin body having one edge thicker than the other.

Fillet—A narrow flat band.

Finial—The ornamental finishing of a pinnacle, gable, or turret.

Finishings—The various works to complete a building after the shell has been erected.

First floor—The story next above the ground floor, so also with second floor, third floor, etc.

Fixture—An article of a personal nature affixed to land or buildings, whether movable or not.

Flange—A plate projecting from the side or end of a piece of wrought or cast metal.

Flank—The return or side part of a body which joins the front and rear.

Flush—A term signifying the continuity of surface of two bodies joined together.

Flutes—Channels on a vertical shaft.

Foil—The small arcs used in tracery to enrich a larger curve.

Foliated—The use of foils in tracery.

Foundation—The basis, natural or artificial, upon which a superstructure is raised.

Frieze—A broad band, ornamental or otherwise, immediately below a cornice.

GABLE—The vertical triangular end of a sloping roof.
Gablet—A similar feature used as an ornament in buttresses.
Gangway—An open passage-way, temporary or fixed.
Girder—A beam used to support a load over a void.
Girt or Girth—The length of the circumference or profile of an object.
Gradient—The vertical rise in a path or road compared with its length.
Grille—An enclosure formed of crossed bars.
Ground plan—The plan of a building taken at the ground floor level.
Guides—Groov s in which a sliding door or shutter runs.

HALF-LANDING — An intermediate landing in a staircase, extending right across the well-hole.
Half-timber—A structure framed of large timbers, the panels filled in with brick or plaster.
Head-room—The space above a flight of stairs necessary to allow free passage.
Herring-bone work—Blocks of material laid diagonally, the end of each butting against the side of the next block.
Hipped-roof—One in which adjacent sides are inclined and form salient angles.
Hood—A projection to protect an object beneath it from the action of the weather.
Housebreaker—A contractor who pulls down existing buildings and clears away the materials.

IMPOST—The capping of a pier or pilaster that receives an arch.
Incrustation—Material, usually decorative, applied by some connecting medium to another body; or a deposit caused by chemical decomposition.
Inlaid work—Work of which the surface is partly cut away and filled in with other materials.
Intaglio—Ornament sunk below the general surface of a piece of work.
Inverted arch—An arch formed below instead of above its springing line.

JACK—A machine used in building operations to move heavy loads.
Jamb—The vertical sides of an opening in a wall.

KILN—A structure in which materials are calcined or burnt.

LABEL—A projecting drip moulding around an aperture.
Landing—The floor terminating a flight of stairs.
Lateral thrust—The outward force exerted by an arched or framed structure.
Lattice—Open work made by crossing strips of iron or wood.
Level—An instrument used by the carpenter and mason to indicate when a line or surface is parallel with the horizon. (See also **Surveying.**)
Live load—A load consisting of bodies subject to motion.
Loose box—An enclosure within a stable in which a horse can be left loose.

MALLEABLE—Material susceptible of extension under the blows of a hammer.
Market sizes—The sizes in which timber and other materials are stocked and sold.
Mezzanine—A story of small height between two higher ones.
Mitre—A plain joint between two similar pieces of material or mouldings bisecting the angle at which they meet.
Mosaic—An incrustation formed with small cubes of marble, stone, glass, etc.
Moulds—Patterns or contours from which work is wrought. A prepared case into which certain fluid materials are introduced to set or cool, or in which plastic materials are given definite forms.
Mouldings—The ornamental contours given to the projecting or receding edges of materials.

NECKING—Any small moulding near the top of a column or pilaster.
Neutral axis—The plane in a beam at which the stresses change, the effect of the stresses being nothing.

ORIEL—A window similar to a bay corbelled out on an upper story.
Out of winding—Material the surface of which is true and free from twist.
Out to out—A dimension taken to the extreme limits of any body or material.

PANEL—A surface enclosed by a frame and sunk below it; an imitation of such a feature in solid material.
Party wall—A wall used for separating adjoining buildings belonging to different owners.
Party fence wall—A wall standing on lands of adjoining owners as a separation of adjoining lands.
Pedestal—A short pier with base and capping under a column or statue.
Pendant—An ornament suspended below the main part of a structure.
Pendentive—The triangular portion of a truncated hemisphere formed by cutting it with two vertical planes each making an angle of 45° on plan with the end of its lower diameter.
Penstock—A small paddle working in a grooved frame for penning back water.
Penthouse—A shed having a lean-to roof.
Permanent set—A permanent change of form produced in an object due to straining the material beyond its elastic limit.
Piecework—Work paid for by the piece or job—not by time.
Plan—The representation to scale of any horizontal section of an object.
Plinth—A square projecting member at the base of a wall or below a moulded base.
Plotting—The process of laying down on paper to scale the plan, elevation, and section from measurements of an existing building or piece of land.
Plumb—Vertical.
Profile—The actual outline of any moulding or other body as shown by a plane drawn perpendicular to its surface.

QUADRANGLE—A square or rectangular court, generally within a building.
Quarter space landing—A landing in the angle between two flights of stairs making a right angle.

RACKING—The tendency to distort a piece of framing diagonally.
Raking—A member inclined at an angle with the horizontal.
Rampant arch—One whose abutments or springings are at different levels.
Re-entering angle—An angle the plan of which is sunk or returned as opposed to a solid angle.
Relievo or relief—Ornament raised above the surface of a piece of work.
Respond—The abutment of the last arch of an arcade.
Return—The continuation of a surface or moulding round an angle.

SAFE load—The permanent load any material or structure will safely support.
Salient angle—The external angle formed by the intersection of adjacent surfaces.
Scale—A line bearing some definite relation to the full size of an object and subdivided for the purpose of plotting.
Scantling—The dimensions of breadth and thickness in a piece of timber; and of length, breadth and thickness of a stone.
Seating—A carefully prepared bed for some object to rest on.
Section—A geometrical representation of an object or building divided by a vertical plane.
Servient tenement—In the case of an easement the tenement on which the obligation is imposed.
Setting-out rod—A board or boarded surface on which work is set out full size.
Settlements—Failures due to the unequal sinking of parts of a building.
Shoring—Temporary timber supports to a building during alterations or when it shows signs of failure.
Site—The plot of ground on which a structure is to stand.
Soffit—The under surface of a vault, arch, or horizontal member.
Span—The clear distance between the supports of a beam or arch.
Specification—A detailed description of the materials and workmanship to be used for any structure.
Spiral stair—One consisting entirely of winders.
Splay—The inclination of one side of an object obliquely to the adjoining side.
Stop—The finish to a moulding or chamfer.
Story—A complete stage in a building extending from one floor to the next.
Superstructure—The upper part of a building carried in the foundations.

TEMPLATE—A metal mould used for cutting masonry and by plasterers in sticking mouldings.
Tie—A member uniting two bodies having a tendency to diverge.
Tobin ventilator—A tube for introducing external air into a room at a suitable level.
Trammel—An instrument for describing an ellipse.
Transepts—The transverse portions of a cruciform building.
Transom—An intermediate horizontal member of a frame.
Trefoil—An ornament having three cusps.
Turret—A small tower often placed at the angle of a wall.

UNDERPINNING—Temporarily supporting a structure with dead shores; extending an existing wall to a greater depth with new foundations.

VALLEY—The internal angle formed by the meeting of two adjacent sides of a sloping roof.
Vault—The arched roof over an apartment; applied also to a vaulted cellar.
Verandah — A light external open gallery attached to a house, and with a sloping roof.
Verges—The edges of the covering of a roof projecting over a gable-end.

WAGON-HEAD VAULT — A cylindrical vault slightly stilted.
Weathering—The covering or special form given to the upper surface of walls or projections on a building to throw off water falling on it.
Well-hole—The open space in a staircase around which the flights are formed; an opening in a floor below a skylight.
Wings—The side portions of a façade or building subordinate to the principal and central portions.
Working drawings—Drawings showing details of a design and serving as instructions to the several artificers.

MATTER, FORCE, AND ENERGY

What is Matter? The Shattered Theory of the Atom. The Essential Property of Matter. The Nature of Electrons. Energy and Electricity.

By DR. SALEEBY

ONLY at the very end of our course shall we discuss the details of the new theory concerning the *structure* of matter. But here we must consider an even more fundamental question—one which has necessarily occupied some of the attention of all the greatest thinkers of the past.

Definitions of Matter. Let us begin, then, by considering some definitions of matter, and thereafter we shall be in a position to see whether we can comprehend the essential nature of the thing defined. The definition of matter that might be given by anyone who had not previously considered the subject would probably be that matter is a *hard* thing, a thing that can be felt, a thing tangible, palpable. Such a man would probably hesitate to call the impalpable air matter. But of course the matter of which water is composed does not cease to be matter whether the water happens to exist in the form of ice or liquid water or water-vapour at any given time. Our idea of matter must include its solid, liquid, and gaseous forms alike.

At the other extreme from the most simple and superficial notion of matter is the definition of the sceptical philosopher, John Stuart Mill, that all we can say of matter is that it is a "permanent possibility of sensation." Whatever that definition may be worth in certain connections, it is of no use to the physicist. A definition which promises to be more satisfactory, and which was long thought to be adequate, is that "matter is that which occupies space." In other words, the essential property of matter is the property of extension—*i.e.* of being extended or of occupying space. In the last resort it was thought we must conceive of matter as a something which takes up room, something no two portions of which can occupy the same space at the same time. It must be impossible to run two portions of matter into another, as the photographer makes a "composite photograph." In other words, matter is impenetrable. A given portion of it may have gaps in its substance into which other portions of matter may be inserted; but where one piece of matter is, another cannot be. "Matter is that which occupies space."

The Atomic Theory. This definition was quite consonant with that atomic theory of matter which until only the other day was thought to be absolutely and ultimately true, whereas now it is known to be only relatively and proximately true—true up to a point. It was thought that matter consists, in the very last analysis, of tiny atoms (a Greek word which simply means that which is indivisible or cannot be cut), and these atoms were conceived as hard, solid little bodies, of various sizes and shapes, like exceedingly small grains of sand. Clerk-Maxwell likened them to "foundation stones": they were "the foundation stones of the material universe, which have existed since the Creation, unbroken and unworn." Like grains of sand, these atoms had the prime character of extension—they occupied space: where one atom was, no other atom could be.

There was another and a profounder way of conceiving these atoms. It might be said that their prime character was the possession of *mass*. Here we may conveniently define this term and distinguish it from *weight*. The weight of a body is a consequence of the law of gravitation. A pound-weight transferred to the moon would still contain the same amount of matter as before, but it would weigh far less, since the force of gravitation exerted by the small moon is much less than that exerted by the earth. On the surface of Jupiter, which is many hundreds of times as large as the earth, the same pound-weight would tax the strength of the strongest to support. On the surface of the sun not even the strongest could lift it. Nevertheless, though the weight of this piece of iron varies according to the force of gravitation,* there is always the same amount of stuff in it: and we express this character by the term *mass*. The mass of a body is a thing absolutely invariable, and would persist even were gravitation abolished, so that it ceased to have any weight at all.

Inertia. It has been said that the prime character of matter is *mass*. This, however, as will be evident to the reader, does not tell us very much; indeed it begs the whole question—for what gives the matter its mass? But this fundamental property of matter may be expressed in another way. It is a characteristic of matter, as we shall subsequently see, that when at rest it will remain at rest until some force is applied to move it: and when in motion, as Galileo first proved, it will continue in motion, in one straight line, for ever, at one constant speed—unless some force is applied to arrest or accelerate or divert it. This property it is from which we have really derived our notion of mass; and the technical name for it is *inertia*. The reader must not imagine that inertia means a tendency to remain at rest when at rest or to come to rest when in motion. Inertia means

* So delicate are the balances employed by modern physicists that it is possible to detect the difference in weight of two cubes of metal, according as they lie side by side in the scale-pan or one upon the other. In the latter case, they weigh less, since the uppermost one is further from the earth, and is, therefore, subject to a weaker action of gravitation.

the property of matter in virtue of which it goes on doing what it is doing, goes on resting when at rest, goes on moving in a straight line at unchanged speed when in motion. Now physicists have agreed that this inertia is really the essential property of Matter.

The Nature of Electrons. This granted, let us anticipate the conclusion of the whole argument, and take it that we must direct our attention not to the atom but to the *electrons* or *corpuscles*, of which atoms are now known to be composed. The ideas which we have formerly entertained of the atoms may be readily transferred to the electrons. *They* are presumably indivisible, it would seem that they occupy space, and they have *mass*. The mass has been measured, and is found to be constant in all electrons. Since they have mass, they have *inertia*, which, as we have learnt, is really the very property of matter that gives rise to our notion of mass. But it is found that these electrons have electrical characters; they are charged with what is called *negative electricity*. [See ELECTRICITY.] At first it was said that they *carry* a charge of negative electricity. Then physicists began to see reasons for doubting whether there was anything there but the charge of negative electricity; whether, indeed, the electrons do not consist of *units* or *atoms* of negative electricity. The inertia which has been agreed upon as the essential character of matter was found to be a property of electricity; it was found to be none other than *electrical inertia*.

So it became necessary to conclude—since matter, to use the words of Mr. Balfour, had been "not only explained, but explained away"—that matter is *made of electricity*, or is merely an electrical phenomenon. Hence the question arises—What, then, is electricity?

Without trespassing upon the subject matter of another course, we may here briefly say that electricity is none other than a mode or form of energy. It can be converted into other forms of energy, such as heat and light; and they can be transformed into it. In other words, matter is merely *a particular form of energy*.

Can Matter Be Transformed? Now, if this be so, if the most fundamental character or property of matter can be identified as a property of electricity, we must ask ourselves whether matter, like other forms of energy, can undergo transformation. This, as we have seen, the physicists of thirty years ago summarily denied. They declared that the units of matter had "existed from the Creation, unbroken and unworn"; that they had upon them the stamp of the "manufactured article." But before this time Herbert Spencer had advanced a theory that everything evolves—the theory of universal evolution; and from this process he did not even exempt matter. When the new theory of matter—that it is a special mode of manifestation of energy—was framed, it became evident that we must seek for proofs that matter, like other forms of energy, can undergo change, or evolution. The fact that such change has been demonstrated may be indicated by the title—"The Evolution of Matter"—of a book lately published by the distinguished French physicist, M. Gustave le Bon, to whom we really owe the pioneer work in our new views of matter.

This leads us to a very serious criticism of a dogma dear to the chemists, and believed by all until within the last year or two—the dogma of the "Conservation of Matter." In the course on CHEMISTRY the reader will see the reasons for believing that, so far as the purposes and experiments of the chemist are concerned, that dogma may be regarded as true. But it can no longer be regarded as *ultimately* true by the physicist. He, as we shall see, believes in the *conservation of energy*, and therefore in the conservation, or indestructibleness, of that of which matter is a particular manifestation. But, in the light of the recent study of radium and radio-activity, he can no longer believe in the conservation or permanence of that particular manifestation of energy which we call Matter.

The "Persistence of Force." A remarkable instance of the insight that belongs only to supreme genius is afforded in this connection by the book, "First Principles," which was published by Herbert Spencer in 1861. Therein he insisted that the physicists of the time were wrong in not recognising that matter is a manifestation of an underlying power or force. He therefore declared that the doctrines of the conservation of energy and the conservation of matter should properly be included in one doctrine, which he called the *persistence of force*, meaning by force the power which is variously expressed as matter or light or electricity or any other form of energy. Spencer's phrase cannot now be used, since the meaning of the word force has latterly been limited and changed, as we shall see: the term energy has taken its place. But now that matter has become as clearly understood by the physicists as it was forty years ago by the great philosopher, we see that the phrase, conservation of energy—to be dealt with fully in its proper place—must now be taken to mean exactly what Spencer meant by his phrase "the persistence of force." Quite lately, Professor Haeckel, of Jena, announced his discovery of a "Law of Substance," which is a somewhat mutilated form of Spencer's law of the persistence of force, or, as it is now called, the conservation of energy.

What Is Energy? When he has read the following chapter, the reader will discover the paradox that, though we now have a far truer comprehension of matter than our fathers had, yet we recognise that we know far less about it than they thought they did. To say "Matter is a form of energy" is easy; but to answer the ensuing question, "What is energy?" is impossible.

Those students of physics, however, who are interested in even greater things than physics will note that the latest knowledge of science is completely incompatible with that doctrine of

materialism to which science has been falsely alleged to lead, but which the most recent advances of science have rendered completely untenable. We may remember, however, in justice to the greatest thinkers of the nineteenth century, that none of them subscribed to the doctrine of materialism. It was by lesser men that this doctrine, now so utterly disproved, was advocated.

It would be pleasant at this point to anticipate the detailed consideration of the greatest idea in physics, the idea of energy. But both on historical and on logical grounds it will be better to concern ourselves first with those facts upon which the idea of energy and the great assertion of its conservation or indestructibleness are based.

Definitions of Technical Terms. At the outset we are faced with an array of technical terms, each of which seems to demand explanation. But, as so often happens, we find on examination that many of these terms overlap or reduplicate one another: and we shall rigidly reject all that are superfluous, since, if superfluous, they are worse in that they make for confusion.

The name still generally given to the primary science of force—which is all-important and soon to be defined—is *mechanics* (from the Greek *mechanē* = a machine); and the terms *theoretical* and *practical mechanics* are often employed. But there are good reasons for confining the word *mechanics* to the study of forces on and in machinery. This use agrees with the obvious derivation of the word; it averts the need for the use of the qualifying adjectives; and it does not interfere with the proper use of a much more suitable word—*dynamics* (from the Greek *dunamis* = force). If we follow, as we well may, the classification suggested in one of the last articles written by Clerk-Maxwell, we must divide the whole subject of physics into two main groups, of which the first consists of the fundamental science of dynamics. All the other branches of physical science are secondary to this; and it is the great contemporary achievement of physics to show that this science is fundamental, that all the other branches of physical science, without exception, depend upon it, and are ultimately referable to it. The laws of light and heat and electricity, for instance, must ultimately be shown to depend upon, or, at any rate, to be absolutely conditioned and qualified by the laws of dynamics. Physics will have reached perfection, in so far as any human science can be perfect, when the fundamental science of dynamics is able to express, in accordance with its laws, all the facts of all the special branches of physics—the movements of the stars and atoms and the ether, the phenomena of light and sound and magnetism.

What Dynamics Is. Dynamics, then, is the science of forces or force; and we must clearly understand, if possible, what is meant by the term. The use of it in English is as a translation of the Latin word *vis*, which was used by Newton in the first book of his masterpiece, the *Principia*. Newton's definition is that, "Force is that which changes or tends to change a body's state of rest or motion."

Evidently, then, the word has a narrower meaning than that which we now attribute to the word energy, for we have seen that the *bodies*, or portions of matter which are acted upon by forces, according to Newton's definition, are themselves to be regarded as manifestations or forms of energy.

Force and Energy. We shall make no progress to a clear understanding of the subject, unless we proceed to distinguish between use of the word *force* and that of the word *energy*. In the whole realm, not merely of physics but of science in general, there has been, and is, no confusion more widespread or unfortunate than the confusion between these two words. To take one instance from thousands, we may quote a sentence which has been used during the last few months as the basis of an important argument, "No power, no energy, is required to deflect a bullet from its path, provided the deflecting force acts always at right angles to that path."

The statement is utterly false, and is, indeed, a flat contradiction of Newton's first law of motion, soon to be discussed; but the absurdity of it is best seen by transposing the words *force* and *energy*, and then reading the sentence again. It contains, of course, a flat contradiction, not only of the most certain law in physics, but of itself. The author has not begun to understand the elements of his subject. But he is not peculiar; the misunderstanding is all but universal. This is partly due to the fact that the distinction requires care for its detection, and to the fact that it has not, until lately, been properly insisted upon by writers on physics, but it is also due to the fact that our use of the word has not been constant in the past. The words have been used synonymously.

Energy includes Force. What we know as the law of the conservation of energy used to be called the law of the conservation of force; and, in ordinary speech and writing, the terms *energy*, *force*, and *power* are all used as if they were synonymous. It would be much better if men would content themselves with the word *power*, which has no very special uses in science, outside mathematics: and if, when using the others, they either stated clearly that they were using purely metaphorical language, or else observed the scientific distinction between them. If this long homily has not been effective we can only regret that we did not make it ten times longer. But the reader will surely have only himself to blame if he falls into the common error after reading this chapter.

The word *energy*, as we shall see in due course, is now used to describe that which is really the underlying and essential fact of all phenomena save those of mind. Certainly this includes the phenomena of motion; and hence the *forces* which are studied by dynamics are manifestations of energy. That is to say, energy includes force, but is immensely wider in its

meaning. Forces are forms of energy, and the study of forces thus throws much light on energy; but though the relations between the two terms are so intimate they must always be distinguished.

The Two Forms of Energy. We must anticipate a little, and observe that energy is displayed in two forms, called *potential* and *kinetic*. Potential energy is as real as any other; but it is latent or unexpressed in anything obvious. *Kinetic energy*, on the other hand, is the energy possessed by bodies when they are in motion (from the Greek *kinesis* = motion): and this kinetic energy they possess in virtue of the forces which have produced that motion.

Now, before he reads a line further, the philosophic reader will insist that he be presented with some account of what we mean by motion. The shortest possible definition of force is "that which changes the motion of a body"; and so it is plain that we have not completely defined force until we have defined motion, since our idea of the one depends entirely on our conception of the other.

Motion may be of two kinds, and every motion of every body, complicated or simple, consists of one or other of these, or of a combination of them. They may be illustrated by the case of the earth. The earth moves *onwards* round the sun; and that is a motion of *translation* (literally, "carrying across."). But the earth also moves round and round on her own axis; and that is a motion of *rotation*. If the earth's motion of translation ceased, we should still have night and day, due to her continued motion of rotation, but we should have no seasons. If her motion of rotation were to cease, we should still have our seasons, but the changes of night and day would cease.

The Two Kinds of Motion. Thus the earth illustrates a comparatively simple case of combination of the two kinds of motion. But the case is not really so simple after all, for astronomers have shown that the sun and his family, of whom the earth is a part, are moving as a whole through infinite space at the rate of about twelve miles a second. No one knows whether this motion is in a circle or in a straight line or in any other of the infinite number of possible directions, but it is certainly occurring. Hence the earth has really two movements of translation—one round the sun, one with the sun to unknown regions—and one of rotation. Indeed, she has many more, but let us take an illustration which the writer has already employed elsewhere. Let us consider the case of one of the corpuscles or electrons that go to compose an atom on the surface of the moon.

Complicated Motion. This corpuscle partakes of the following motions at any rate, and probably of many more. It is moving within the atom, probably revolving round the centre of the atom as the earth revolves round the sun. The little corpuscle may also be rotating on its own axis, as the earth rotates on hers. The corpuscle also partakes of that vibratory or to-and-fro movement of the atom as a whole, which constitutes what we call heat. It is also being drawn gradually towards the centre of the moon as she cools and shrinks. It is also in motion as the moon rotates on her own axis. It is also in motion as the moon revolves around the earth. It has another motion due to the fact that the moon accompanies the earth in her revolution or movement of translation round the sun. And, finally, this tiny corpuscle is moving, with the atom of which it forms a part, and with the moon and the earth and the sun, through space—apparently towards the bright star Vega, familiar to every stargazer as the most prominent star of the constellation Lyra. In addition, it is quite probable that the solar system and Vega and all the other stars we know are in motion together, as a gigantic whole, through boundless space.

Our illustration is more impressive than that often quoted, of the man who walks backwards along the deck of an onward-moving ship—which, in its turn, partakes of all the movements of the earth. Let us consider the corpuscle in the atom on the moon; or the man on the ship. Though each partakes of all these motions and many more, yet we cannot but believe that each is moving only in one direction in space at any given moment of time. The *resultant* of all the forces impressed upon the man or the corpuscle is that he or it has an absolute motion in a certain direction at a given moment—as a consequence of the interaction of all the various motions which we are able to recognize. But it is plain that no one can say what the absolute motion of the man or the corpuscle actually is—at what rate or in what direction.

Limitations of Knowledge. Thus we have placed ourselves in a position to see one of the most profound truths that we can recognise—a truth of equal importance to the physicist and the philosopher. This truth is that we know nothing whatever as to the absolute motions of bodies in space, but only as to their relative motions. We can say positively that a train is moving at the rate of sixty miles an hour. But, indeed, the train is moving eighteen miles a second in one direction, with the movement of translation of the earth; twelve miles a second in another, with the movement of the solar system as a whole; a thousand miles an hour—if at the equator—in another, with the movement of rotation of the earth, and so forth.

To be continued

A SURVEY OF MUNICIPAL CAREERS

The Sphere of Municipal Activities, showing the Scope for Careers in Local Government. Local Authorities of London and the Country.

By ERNEST A. CARR

Local Government of the Kingdom. The amazing growth of the Municipal System was briefly traced in the first article in this Course. In its present form this branch of our great Civil Service is a very elaborate and complex organisa ion, covering the whole country with a network of local authorities of various grades and differing powers, such as the Boards of Guardians, District Councils, corporate Boroughs, and County Councils. During the course of our scrutiny of the Municipal Service we shall frequently have to refer to these and other local bodies; and it is absolutely essential for any practical understanding of the subject that some clear idea of their powers and duties should be gained. Let us therefore consider briefly the way in which the administration of local interests is parcelled out among them.

Least among all local entities—the units of the system, as it were—are the parishes, which are grouped into urban and rural. Of these, the urban parishes have practically no separate administrative existence; they are banded together into larger districts, as will be presently explained. Rural parishes with a population of less than 300 are managed by that simplest of municipal bodies, the Parish Meeting. Its powers are limited to the lighting of the parish and the establishment of public libraries, baths and wash-houses.

The Small Elective Bodies. Rural parishes of over 300 inhabitants are entitled to elect their own *Parish Councils*, which have power to appoint only two paid officials, the clerk and assistant overseer and the parish lamplighter. It is the first rung in the ladder of self-government—the beginning of local authority, offering the first opportunity that comes to a country boy of a post in the public service near his own home.

Next above this tiny model of local government stands a much more influential body, the *Rural District Council*, which employs a staff relatively small but comprising remunerative positions. In addition to clerks, collectors and assistants, the Council employs a medical officer of health, surveyor of highways and sanitary surveyor or inspector, numerous foremen and roadmen, and, in certain instances, a hospital staff besides. In more populous areas the urban parishes are associated to form an urban district, under the control of the *Urban District Council*, an elective body, like its rural neighbours, but enjoying considerably grea'er powers.

The Urban District Council derives most of its authority from the Public Heal'h Acts. Its duties, like those of other municipal bodies, are in part obligatory, in part optional or adoptive. Among the former are the enforcement of sanitary measures, the scavenging of roads, the maintenance of all highways in its area except the main roads, the protection of public rights of way, and the task of enforcing the Acts relating to factories and workshops.

Its optional powers are far wider. The District Council may undertake sewage works, establish libraries, hospitals, parks, markets, baths and wash-houses, and undertake waterworks, gas works, and electrical generating stations. It may make new roads, form cemeteries, and frame regulations and by-laws on an endless number of matters affecting the health, comfort, and safety of the district. It has large borrowing powers for works of a permanent nature, and may promote private bills in Parliament for the furtherance of local needs. If the district numbers more than 20,000 inhabitants, its council (under the Education Act of 1902) is the local authority for maintaining and enforcing elementary education. As a precaution against irregularity in expenditure, the District Council's accounts and those of all larger municipal bodies are audited each year by an auditor appointed by the Local Government Board—a branch of the National Civil Service created expressly to supervise the actions of local authorities.

Town and County Councils. The Town or Municipal Council stands at the summit of local self-government. It has all the powers enjoyed by an urban district authority, and many others besides. In the case of a smaller borough, it may be controlled by the county authority and be dependent on that body for its police and elementary education, and the maintenance of its main roads; otherwise the corporation is entirely self-controlled, and (subject to cer.ain legislative restrictions) administers local needs exactly as seems good in its own eyes.

It would be tedious merely to name the many duties entrusted to the Town Council. It is empowered to erect a town hall and other municipal buildings, to provide hospitals, parks and markets for the people, to deal with nuisances and sanitary measures of all kinds, to make by-laws innumerable, and generally to take what steps seem necessary "for the good rule and government of the borough." The larger corporations boast a stipendiary magistrate, maintain their own police force under the control of a watch committee of the council, and are entrusted with the important duties connected with elementary and secondary education.

Certain ancient corporations—such as Berwick, Exeter, and Norwich—have preserved from of old what are known as "county rights," making them wholly independent of the county authorities.

The County Councils. All boroughs with a population of over fifty thousand were raised to the status of County Boroughs by the Local Government Act, 1888. In each case the governing authority is known as the *County Borough Council*, and possesses the powers of a county authority as well as those of a municipal corporation. Many of the boroughs and county boroughs enjoy special privileges of their own, either by statute or by charter.

The County Councils are elective bodies acting for the several counties, except the districts of the county boroughs. Their very responsible duties in respect of main roads and education have already been mentioned. They also control the county police, maintain local lunatic asylums, reformatories and industrial schools, prevent river pollution, receive the county rate, grant licences for music and dancing, as well as for theatres and racecourses, and enforce certain statutes and by-laws. Lastly, they are required to regulate and supervise generally the work of the various local bodies within the county. For all these duties a large professional and clerical staff is needed.

Apart from the Poor Law and the special characteristics of London, our brief survey of local government in England and Wales is now complete. It may be useful to add the number of local authorities of the several grades described. They are as follow:

Parish Councils	6706
Rural District Councils	672
Urban District Councils	817
Town or Borough Councils	250
County Borough Councils	66
County Councils	62
Total	8573

Scotland and Ireland. Scotland and Ireland were not affected by the Municipal Corporations Act of 1882 and the Local Government Acts of 1888 and of six years later—the three statutes that have swept and garnished the English municipal system. And although each country has since been remodelled on somewhat similar lines, their internal affairs remain, perhaps, less effectively administered and less under popular control than in England.

In Scotland, for instance, the county authority is vested in a council not unlike its English model, but without aldermen, and possessed of fewer powers; whilst sheriffs, appointed by the Crown, exercise certain functions which, south of the Tweed, are vested in elective bodies. The Scotch corporations or burghs are, if anything, more powerful and more democratic in organisation than the English.

One curious feature of Scotch town councils is their control of the "Common Good Fund"—the common purse of the borough, which is readily available for any objects directly beneficial to its inhabitants. English corporations, with their strictly guarded finances, and the fear of "surcharges" always before their eyes, would welcome this characteristic of the towns beyond the Tweed.

A Model for Municipalities. Without discussing Scotch local government in detail, it will suffice to add that, in its leading cities at least, it is generally acknowledged to be strikingly successful. Glasgow, for instance, stands as a model of municipal courage and foresight. In the words of an expert, "The Corporation has carried out bolder schemes and undertaken greater and newer enterprises than any other public body. The vast improvement scheme which began in 1866 has revolutionised the physical and moral condition of the people. Beginning with the clearance of the most insanitary areas and the most densely crowded centres of the city, the Improvement Trust constructed wide streets where congested courts formerly stood; it presented the city with a magnificent park; it set an example nearly thirty years ago in the erection of municipal lodging-houses on a large scale; it has carried out great building schemes. The Health Department has adopted an admirable system of sanitary vigilance and beneficent coercion, which has all helped to improve the health and social condition of the people. The introduction of water supply from Loch Katrine was also of incalculable benefit."

Municipal trams, telephones, gas, electric lighting, ferries, baths, markets, slaughter-houses and many other municipal additions to the comforts of life are enjoyed by the Glaswegian.

Incidentally it may be mentioned that these far-reaching activities involve the maintenance of a colossal staff, many members of which enjoy very handsome salaries.

Local Government in Ireland. A clean sweep of the old grand jury system, and of many other municipal privileges and abuses, was made by the passing of the Local Government Act for Ireland in 1898. Internal administration is still very limited, and is hampered by many difficulties and prejudices, but it has been greatly stimulated by the new conditions, and the outlook is more promising than it has ever been. The new Irish system is electoral, resting on the Parliamentary franchise. The counties are divided into urban and rural districts. Of these, the former class comprise six county boroughs, a number of urban sanitary districts raising their own rates and administering the Public Health and Housing of the Working Classes Acts, and certain towns controlled by commissioners instead of councils.

The rural district councils, acting under the control of the county authorities, have very limited powers in respect of public works, water supply, and the Public Health Acts. For their funds they are dependent on the county councils, which levy a general county rate on all save urban districts. Outside these last-named districts the administrative power is mainly in the hands of the County Councils. Irish municipal work is, indeed, still in its infancy. Large staffs and high salaries are almost unknown outside the offices of the county councils and leading boroughs; and although indications of a general advance in local activities are not wanting, it

will be long ere Ireland offers capable municipal officials a field in any way comparable with that afforded by England.

The Rule of London. London not only forms the most striking of object-lessons in the possibilities attending a skilful and enterprising policy of government—it has an especial interest for us as the widest of fields for ambition in the Municipal Service. For both reasons it will be worth our while to select the English capital for a somewhat detailed study of municipal work. From one point of view we shall have to consider the colossal difficulties and problems involved in the administration of so vast a city; from the other, our interest will be rather in the officials engaged in that task—their salaries, duties, and prospects.

Long the despair of municipal reformers, and afterwards the most complex and vital among the many puzzles confronting them, the Metropolis bids fair to be their greatest triumph. The commercial and political centre of the Empire, London stands alone among cities. With a population greater than that of Scotland, an area rated at more than forty millions sterling, and with property and commercial interests of literally incalculable value, it has a supreme claim to sound, bold, well-organised self-government.

Yet that claim has been almost disregarded until within the last 20 years. The town was suffered to grow up as best it could, in a tangle of jurisdictions and interests that strove like weeds in an untended garden. The policy one parish adopted was opposed by its neighbour; and in the absence of any strong central authority, no effective measure for the betterment of London as a whole was possible. Situated in three counties, with a wealthy and independent corporation at its centre, the capital was divided into a medley of parishes, liberties, outlying parochial areas, and other quaint elements of confusion. Lighting, drainage, rating and other authorities acted independently, without any regard for uniformity or system. The old Metropolitan Board of Works, it is true, did something in the direction of street improvements down to its timely decease in 1888; but it was neither a strong nor a popular body, and its efforts left municipal London a veritable hotch-potch still.

Creation of the "L.C.C." A great mass of incongruities and anomalies was shattered at a single blow by the Local Government Act of 1888. London was created a county in itself, instead of owing a divided allegiance to Middlesex, Kent, and Surrey; and over the various and often conflicting local bodies was placed a really strong representative authority, the London County Council.

Unlike the Board of Works, which it replaced, this was from the first a body chosen directly by the electors, and its popular character has enabled it to go far in the task of simplifying London government and reducing it to a system. Later legislation has aided this work by abolishing various so-called Commissioners and transferring their powers to elective councils; and in 1899 a statute was passed which operated powerfully in the same direction. Its effect was to replace the vestries, district boards, and other perplexing sub-authorities by 28 Metropolitan Borough Councils, with frontiers such as reasonable men could understand. Finally, in 1903, the Education (London) Act handed over all the powers and belongings of the London School Board to the County Council.

The problem of unifying London is by no means yet solved, however. The County Council has practically no control over the heart of its area—that famous square mile belonging to the City Corporation. Certain other authorities exercise special or local powers within the spheres of the county, city, and borough councils. The Police Commissioners, Thames Conservancy, and Asylums Board are instances in point. There are many Londons, each with differing boundaries—the administrative county, the police area, the Londons of the Post Office, County Courts and Police Courts.

The County Council's Great Work. There are thousands of careers open for young men and young women under the London County Council. It is not easy to convey an adequate notion of the amount and varied nature of the Council's work, for which task it has been equipped by Parliamentary powers considerably greater than those possessed by any other county council in the Kingdom. It expends every year some eight and a half million pounds in the course of its labours. For the education of London's children it employs 21,000 teachers and 1600 other officers. The Council's asylums occupy another 3,600 permanent officials, its tramways 3,000 more, and the remaining departments an additional 5,500, exclusive of several thousand workmen and temporary assistants of various sorts. The total permanent staff of the L.C.C. is thus over 34,000 of all ranks—a larger army than that with which Napoleon won his stubbornly contested victory at Arcola.

This great force of workers is grouped into a number of departments, each in charge of a responsible and highly paid officer, and controlled by an expert committee of the Council. A reference to the activities of those divisions will show very clearly the variety and vastness of the Council's undertakings.

The engineering branch, for instance, numbering 1,314 employees, is occupied chiefly in the gigantic and supremely important task of dealing with London's main drainage. It has charge of 288 miles of main sewers, draining an area of 140½ square miles and discharging almost exactly 250 million gallons daily. When there is added to the labour involved in treating this enormous volume of sewage, the charge of London's bridges, and such occasional engineering feats as constructing the Blackwall Tunnel, it becomes clear that the chief engineer's stipend of £2,000 a year is fully earned.

The Council's Fire Brigade forms an equally large department, justly famed for its smart, well-trained staff, and up-to-date equipment. Including the river section, its services are invoked about a dozen times a day.

Outdoor Careers. The 5,000 acres of parks and pleasure-grounds maintained by the Council need merely passing reference. The works department, with a small permanent staff of building and engineering experts, undertakes numerous works, such as artisans' dwellings, fire stations, asylums, and street-making, upon which over 2,000 workmen are constantly employed. The Public Health branch, under medical experts, supervises the work of the local sanitary authorities, inspects the seamen's and common lodging-houses of London, and punishes any lack of cleanliness, keeps a watchful eye on outbreaks of infectious disease, frames new bye-laws and regulations on Public Health matters, and in many other ways does invaluable work in preserving the well-being of the citizen.

Nowhere has the enterprise of the County Council been bolder or more successful than in the huge schemes of its Improvement Committee for drastic alterations, designed to add to the dignity and usefulness of certain of London's main thoroughfares, and to render the aspect of the capital more worthy of itself. If London's ugly, awkward and narrow streets are becoming things of the past, it is largely due to the vigorous policy of this supreme authority. A great and valuable work is performed by another committee of the L.C.C. in the maintenance of London's 17,000 lunatics and epileptics. The annual expenditure is £520,000, of which no less than £160,000 is devoted to the salaries and wages of the large staff of doctors, nurses, attendants, and other officials necessarily employed in the county's nine asylums.

Under the heading of municipal locomotion we may include the Thames steamboat service, organised in the spring of 1905, the 48 miles of municipal tramways in North London leased to a commercial company, and the 46 miles on the south side of the Thames owned and worked by the Council itself. The Council's tramway policy of low fares and liberal wages has been amply justified by the event. The efforts made by the Council to abolish slum areas, and to provide cheap, wholesome housing accommodation for the working classes in their stead, form another interesting chapter in the long record of its stewardship. Schemes at present in hand provide for the housing of no fewer than 80,000 workers.

Education. There is little need to enlarge upon the educational work of the Council, its latest and most colossal undertaking. The whole system of elementary education has been taken over bodily from its creators, the now defunct London School Board. Briefly, the duties involved are the teaching of 550,000 children in ordinary schools, the maintenance of truant and industrial schools for the wayward and of special centres for the defectives, and carrying on evening schools for manual, technical and domestic education, and for the training of a large staff of pupil teachers. The sum paid annually in teachers' salaries alone already reaches £1,600,000. To this task the new education authority has added a liberal and comprehensive system of scholarships, enabling clever children, however poor their parents may be, to climb the educational ladder to its topmost rung.

Diversity of Work. Other activities there are which must be passed over unnoticed, but our review of the Council's work must not omit the services performed by its "Public Control Department." The work of this department has been admirably summarised by an authority in municipal affairs. "The diversity of its duties" (he writes) "ranges from regulating the feeding of babies to the inspection of dynamite and the control of coroners' inquests. Outside the City, it checks and inspects all weights and measures; tests the accuracy of gas meters, the milk-can and the beer-glass; and ascertains that the coal is of correct weight and guaranteed quality. It protects us (Londoners) from the danger of fire arising from storage of inflammable liquids, and has done its best to secure the safety of petroleum lamps—the light of the poor. It extends its protective influences to the animal world, and stamps out contagious diseases in horses, cattle, and other animals."

By such varied means the greatest of the County Councils is occupied in protecting its citizens and making London the best governed city in the world. The officers employed to carry out its designs are liberally remunerated for their efforts. The Council's pay-list includes five posts of £2,000 and twelve others at figures between £1,000 and £1,500. There are numerous appointments carrying intermediate salaries, down to the £500 which represents the maximum attainable by staff officials not singled out for special promotion.

The Borough Councils. Since 1899 the local control previously exercised by the London vestries and district boards of works has been in the hands of certain special authorities created by the London Government Act of that year. These Metropolitan Borough Councils, as they are called, have certain characters distinguishing them from the general Borough Councils of the provinces. As sanitary authorities they possess special powers under a Public Health Act limited to London. They maintain all main roads in their area, may undertake street improvements, and may promote bills in Parliament. Generally, however, their work resembles that of the county borough authorities described earlier in this Course; but the Metropolitan boroughs, as a rule, require the services of a larger staff, and their average level of remuneration is higher than prevails in the provincial offices.

An analysis of the actual figures relating to the staff of a typical Metropolitan council office (without electrical works) gives the numbers employed as follow:

Surveyors' Department	50
Rating and Registration	32
General Staff	35
Libraries	35
Public Health Department	17
Burials Department	6
Total	175

The salaries include that of Town Clerk, £1,150; Solicitor, £750; Medical Officer of Health, £1,000; Surveyors (two), £750 each; Public Analyst (by fee), about £400; Accountant and Valuer, £330 and £300 respectively. Among the clerical staff, the highest post carries £420, the rank and file rising by regular increments to £200. Sanitary inspectors reach about the same maximum. The four leading librarians receive respectively £350, £250, £230, and £150, with a residence apiece; whilst the remuneration of the rate collectors varies from £230 to £160 a year. These figures will serve to indicate the wide scope afforded by the offices of the twenty-eight Metropolitan Borough Councils.

The City Corporation. In the very heart of modern London, with its newly created authorities, exists the most ancient and famous of all municipalities, tracing its history back nearly a thousand years. The position of the City Corporation is singular on more than historical grounds. Geographically its area is insignificant—a mere 672 acres, or just over a single square mile, which is about one-seventh the size of Camberwell Borough. Yet it is by far the wealthiest and most influential corner of London—the capital's commercial capital.

The City is governed by a Court of Common Council, composed of the Lord Mayor, 25 Aldermen, and 206 Common Councilmen. The Lord Mayor himself is elected each year from and by the Court of Aldermen, on the nomination of the Livery. The Common Councilmen are appointed annually by the votes of the Livery, which is an electorate composed of members of the ancient Trade Guilds or Mysteries. Each of the guilds was originally a defensive association of traders engaged in the same calling, though nowadays members of the Armourers', Girdlers', Bowyers', or Patten Makers' Guild would be puzzled if called upon to exercise their craft.

Municipal Posts in the City. Always an independent county as well as a municipality, the Corporation, though it has so far yielded to modern influences as to admit the London County Council to some share in its administrative control, still preserves many of its quaint and unrivalled privileges of self-government. It elects its own Sheriffs, has its own Commission of Lieutenancy and Justices of the Peace, and its own Courts of Law. More singular still, it possesses a body of police which (says that expert in matters municipal, Mr. Robert Donald) "is the only really municipal police force in the country, as it is independent of the Home Office."

For almost all purposes of administration the Court of Common Council appoints its own staff of officials. It controls the five principal markets in London, maintains a museum, art gallery and several important schools, owns four of the bridges over the Thames, and lights, paves, and cleanses in faultless fashion the streets within its area. Most important of all, the City Corporation is the port sanitary authority of London, exercising sanitary rights from Teddington Lock to beyond the Nore, and maintaining a special medical officer and a staff of inspectors to prevent contagion from entering the Thames.

The majority of City appointments are made or approved by the Court of Common Council or its committees. In respect of salaries the Corporation is certainly the most liberal municipal employer in the Kingdom. Of its relatively small staff, eight officials receive £2,000 a year or more, and nine others are paid from £1,000 to £1,500. The stipend of the Clerk to the Lord Mayor is £1,150, and that of the librarian, £850; whilst the responsible office of sword-bearer is remunerated with a salary of £600.

London's Minor Authorities. To complete our review of London government we must glance at one or two minor authorities, whose work is restricted to a few special functions. The foremost of these is the Metropolitan Asylums Board, a central authority created for the reception of insane paupers, and of those suffering from smallpox and other infectious diseases. It has long outgrown its original scope, however; and besides maintaining five imbecile asylums and two schools for afflicted children, possesses twelve fever hospitals, at which other than pauper patients are admitted. It also maintains a training ship for workhouse boys, an ambulance service over the whole of London, and several other undertakings. The appointments under its control are chiefly medical, nursing, and domestic.

London is singular among towns in that the control of its huge police force—except in the City proper—is neither municipal nor county, but is vested in a separate authority, the Commissioners of Metropolitan Police, who are amenable only to the Secretary of State. They play no other part whatever in the government of the capital.

The Metropolitan Water Board is a recently constituted body composed of representatives of local county, borough and district councils, which has taken over the systems of the eight water companies supplying the Greater London area, in order to manage them in the interests of the ratepayer.

The River. The last of the special authorities to be considered, the Thames Conservancy Board, is another assemblage of representatives of various local and national interests, with a sprinkling of trade delegates. Its functions are of vast importance to that waning feature in commercial life, the Port of London. Briefly, they are to maintain the river in an efficient state for navigation, and to prevent its pollution. For these purposes a large staff of inspectors, river keepers, boatmen and other waterside officials is constantly employed.

To be continued

A WOMAN'S CHOICE OF A CAREER

RECENT years have witnessed the entry of women into many fields formerly deemed to be exclusively for men. These details regarding some of the principal careers for women may help to solve the problem, "What shall we do with our girls?" The full courses in the SELF-EDUCATOR concerning each profession should be consulted by all who would enter upon any of these careers. Some available careers which are equally open to both sexes are not touched upon here, as they are noticed in a previous article on page 161; and for other openings not included in this summary the reader is advised to consult the fuller sections of the SELF-EDUCATOR.

Accountants. For women with an aptitude for figures, there are openings as accountants and auditors. The training is the same as for men. The candidate should be sufficiently well educated to pass the preliminary examination of the Institute of Chartered Accountants, although membership of that body is still denied to women. She should be articled to an accountant for five years, and pass the three prescribed examinations. The cost of training is from £100. Age limit from 18 to 21. Women are frequently employed to audit the accounts in girls' schools and colleges. [See pages 148-9.]

Bookbinding. This is work which may often be done by women in their own homes A thorough training is necessary, as well as artistic instincts. A twelve months' course of training costs about £70. It is fairly remunerative.

Chromo-lithography. Three years are necessary to become fully acquainted with the work. There are many openings both at home and in the Colonies for workers who are well qualified. Salaries average from 20*s.* to 35*s.* a week.

Church. In the United States hundreds of women have been ordained, and are practising as ministers, but there are, so far, no openings of the kind in the United Kingdom, although one lady has recently been appointed pastor of a church in a provincial town. A number of women find employment as church workers, but this work is never well paid. Bible women, when trained at one of the homes in connection with various charitable organisations, are paid from £40 to £60 a year. The Church Army Mission nurses are paid 14*s.* a week, with lodging.

Civil Service. An increasing number of women find employment as clerks in the Civil Service, chiefly in the various branches of the Post Office. Posts are obtained by open competitive examination, in which a high standard of proficiency must be attained, as competition is very keen. The examination is in the usual English subjects and two foreign languages. Fee 7*s.* 6*d.* The age limit for women clerks is from 18 to 20, salary to begin £55, rising to £100 per annum. One month's holiday is given, and a pension or gratuity on resignation. For girl clerks, the age is from 16 to 18, and the beginning salary £35. At the end of two years they may be promoted, if competent, to the rank of women clerks, starting at a salary of £55. Female sorters in the Post Office pass an examination in English. Age limit 15 to 18. Salary begins at 12*s.* a week and rises to 21*s.* 6*d.* Between the ages of 18 and 25 sorters may enter the open competitive examinations for women clerks. The security of tenure, short working hours, and length of holidays, together with the prospect of a pension, make this a very desirable career for women.

Commercial Travellers. A few women are employed as commercial travellers in England, and a much greater number are doing well as such in the United States. The posts obtained in this country are chiefly in connection with the drapery trade, and are usually given to employés who have shown special ability and are well acquainted with the business of their firm.

Dairy Work. The training at one of the dairy schools recognised by the Board of Education lasts from six to twelve months, and costs about £1 to 30*s.* a week, including board and residence. Salaries paid to dairy teachers under the county councils range from £1 5*s.* to £3 a week. Superintendents of dairies on private estates are paid from £25 to £60 a year with board and residence.

Dentistry. There are few women dentists to be found in England, although numbers are practising in the States and Canada. The Royal Colleges of Surgeons of Dublin and Edinburgh grant the diploma in Dental Surgery to women, who may then be registered for practice by the Medical Council. The cost of training is somewhat less than for medicine.

Dispensers. The highest training of women dispensers consists of a three years' apprenticeship to a qualified chemist, to whom a fee of from £50 to £70 may in some cases have to be paid. Training and examinations are as for men. [See page 161.] Women have obtained posts as dispensers in hospitals and other institutions at from £80 to £150 per annum. There are also openings as dispensers to medical men, who often accept the certificate of the Apothecaries' Assistants' Examination, together with a course at a school of Pharmacy as sufficient qualification. The average tuition fee for a three months' course at a school of Pharmacy is about ten guineas.

Domestic Science. Technical Education in Domestic Science is a development of quite recent years, and the profession of domestic science teacher is one which is very suitable for an active woman of good education. Training lasts about two years; the cost of the complete course varies from £18 18*s.* to £55. Instruction in cookery, laundry work, dressmaking, millinery and hygiene is given in schools of cookery throughout the country, also in both elementary and secondary schools. Salaries of teachers for these posts range from £70 to £250 a year. There are also posts obtainable under borough councils, and sometimes particularly good colonial

appointments are offered to domestic science teachers trained in England.

Dressmaking. There are always plenty of openings for clever women in dressmaking. Apprenticeship lasts two years. In a good house the premium, if indoors, is usually from £60 to £100, and, if the apprentice lives at home, about £30 to £50. On expiry of apprenticeship a post is usually taken as improver for about six months, when assistants' posts may be obtained at from 10*s*. to 16*s*. a week, rising in the case of a good worker to £2 a week. A really first-rate fitter can obtain £5 a week. Women who mean to start in business as dressmakers should spend at least some months at the practical part of the work, and should understand stockkeeping. To start in London at least £1,000 capital would be necessary, as credit must be given.

Florists. Apprenticeship is usually for three years. During part of this time wages of 3*s*. to 5*s*. a week are paid. Afterwards assistants may earn from 15*s*. to 25*s*. or 30*s*. a week. Premiums of from £5 to £30 are usually paid for learning florists' work.

Gardening. A course of instruction at a horticultural college such as that at Swanley or the Lady Warwick College, Reading, usually lasts from two to three years. Fees are from £70 to £80 a year, including board and residence. Instruction is given in horticultural science, flower, fruit, and vegetable growing (out of doors and under glass), market work, packing and storing. Dairy work, poultry farming, and bee-keeping are extras. When trained, some students obtain positions as lecturers and teachers. Lady gardeners are seldom paid more than £1 a week to begin with. They frequently take resident places as companion-gardener to some lady. To start in business as a market gardener it is necessary to have at least £900 capital.

Hairdressing. In the opinion of some hairdressers there are openings for women in this business. The term of apprenticeship is two years. When the various branches of the work are thoroughly mastered, an assistant can command from 15*s*. to 35*s*. a week, usually with a percentage on all articles sold.

Hygiene. There are many well-paid appointments open to educated women who are trained in hygiene. A certificate may be obtained from Bedford College, London, by students who pass the examination held at the end of one year's course in scientific and practical hygiene. The fee is 27 guineas. A shorter and less expensive course may be obtained at the National Health Society, Berners Street, London. The fees there are 15 guineas for six months. For women so qualified, posts have been held as Factory Inspectors, Sanitary Inspectors, Lecturers under the County Councils, and Inspectors under the Shop Hours Act.

Illustrating and Fashion-Plate Drawings. Many women who have received an art training can command good salaries as illustrators of books, magazines and ladies' papers. This is a profession which is not overcrowded. Women who desire employment of this kind should send sets of specimen sketches to the editors of some of the illustrated papers.

Indexing. Openings for work of this kind are always increasing. Indexing is a lucrative employment suitable for well-educated women. The training under an experienced indexer lasts from six to nine months, and the fees are from 15 guineas. Women indexers have recently been appointed by the London County Council. The work can be done at home. Charges range from £2 2*s*. to £4 4*s*. per thousand entries.

Journalism. The prospects for women in journalism are fairly good. Payment for special or occasional contributions is equal to that of men, although for regular reporting work women are paid less. Women are also handicapped at the outset by their inability to obtain the thorough routine training which is usually gone through by men, but, given a capacity for hard work, they frequently achieve success.

Laundry Work. There is a steadily growing demand for thoroughly well-trained women in laundry-work, both as actual laundresses and as superintendents or manageresses of laundries. The course of training for manageresses in a good laundry usually lasts from three to six months. The fees are from £5 to £10. When the training is completed, if the pupil is thoroughly competent, she may obtain a position as forewoman or assistant manageress at a salary of from £1 to £2 10*s*. a week. The hours of work are long, being usually from 8 a.m. to 8 p.m., and the work is hard. Manageresses are paid from £2 up to £5 a week.

Librarians. There are not so many openings for women as librarians in this country as in the United States or Canada, nor are the salaries paid in England sufficiently remunerative to induce women of good education to take up what would otherwise be suitable and congenial work. The best plan to pursue in order to become a librarian is to attend the classes at the London School of Economics and enter for the Examination of the Library Association. The average earnings of a woman assistant in our public libraries is £50 a year. Head librarians are paid £100.

Medicine. Women who desire to qualify as medical practitioners are subject to the Regulations of the general Medical Council in the same way as men. Women are admitted to medical degrees and diplomas equally with men, by the examining bodies of most British Universities, with the exception of Oxford and Cambridge. Posts are open to women doctors in the Post Office, and under the London County Council; also in connection with many hospitals and dispensaries throughout the country. Many women are earning good incomes in private practice in Great Britain, while, owing to the fact that no man can enter the zenanas of the high-caste Hindoo, India offers a wide field of labour. Appointments are open both under Government and in connection with some of the various missionary bodies, the Dufferin Fund, etc.

Millinery. Apprenticeship lasts two years; at the end of first year wages about 5*s*. weekly. Assistants in wholesale milliners' receive from

12s. to 30s. a week. In the West End shops engagements are often for the season only, when a very experienced hand can command from £2 to £4 or £5 a week. To start in business in London about £400 capital is necessary, also technical training and a taste for the work. For such women the prospects of success are good.

Needlework—Art. At the Royal School of Art Needlework, South Kensington, training lasts two or three years. Fees for two years' certificate course £20 a year, and for three years' diploma course £10 a year. Hand embroidery, etc., is taught to amateurs. Fee for six lessons, 21s. to 30s. There are many other schools of embroidery in London and the provinces. There is a fair demand for work of this kind in connection with churches. It also commends itself to some women as being work which can frequently be done at home.

Nursing. Hospital nurses receive a training of three years in a hospital to which the average age of admission is from 23 to 30. Some hospitals require a fee of from £10 to £50. Probationers are usually paid from £8 to £15 a year with uniform. When the period of training is over the majority of nurses take up private work, usually joining one of the Co-operative Associations of Nurses. In these societies the nurses retain their own fees, only deducting an agreed percentage for expenses. Their salaries average from £72 to £110 per annum. Private nursing may also be undertaken for an institution at a fixed yearly salary, ranging from £20 to £40, with uniform, board and residence. Nurses who join Queen Alexandra's Imperial Military Nursing Service, for work at home and abroad, are paid from £40, in addition to quarters, board, allowance, etc. Sisters receive £50 to £65. Matrons, £75 to £105, and the Matron-in-chief from £300 to £350. They also receive a pension upon retirement. Age for appointment from 25 to 35. In the Naval Hospitals head sisters are paid £125 to £160 in addition to quarters and uniform. Nursing sisters receive from £37 10s. to £50, with board allowance of 15s. a week. District nurses in London or the Provinces are usually trained for two years in a general hospital, and six months in a district nursing home. Salaries from £26 per annum, with everything found.

The training of maternity nurses is usually from three to six months in a maternity hospital or infirmary. Fees for this are usually £10 to £26. The Obstetrical Society of London holds examinations four times yearly, at which certificates are granted to successful candidates. Fee, 21s. A maternity nurse's fee varies from £6 6s. to £21 for a case.

Photography. A course of instruction in photography at the Regent Street Polytechnic costs £52 10s., in addition to which a student should work for a few months as a pupil in some good studio. To start in business in London at least £500 capital would be necessary, although considerably less would suffice for the Provinces. Retouchers in photographic studios may be paid from 25s. to 40s. a week. For working up, 17s. 6d. to £2 10s. a week.

Physical Training. There appears to be a wide and, so far, unfilled field for women of good physique who are thoroughly trained gymnastic teachers. The course should extend over two years, and costs from £50 to £100, exclusive of living, or as resident pupil at a Physical Training College, from £90 a year. Resident teachers in schools are paid from £40 to £50, non-resident teachers from £100.

Printing. Apprenticeship lasts for three or four years, but wages begin after about six months. At the Women's Printing Society a premium of £5 is paid, and a small weekly wage is received from the start. The average rate of pay is 24s. a week, but it sometimes rises to 34s. Women compositors who can spell well seldom fail to find work.

Sanitary Inspectors. The number of appointments open to women under the County Councils is steadily increasing, and the work which has been done by those already appointed has proved satisfactory. The age limit for London applicants is from 25 to 40, and the requisite qualification is the certificate of the Sanitary Inspectors' Examination Board; for the provinces the Sanitary Institute Certificate is accepted. Salaries vary from £80 to £110 per annum, and rise to a maximum of £150.

Secretarial and Clerical Work. Women who, in addition to a sound English education, have undergone a special business training in typewriting, shorthand and book-keeping, can obtain posts at from 30s. to £2 a week. If to these qualifications a knowledge of commercial French and German is added, salaries may rise to £3 a week.

Shop Assistants. Women shop assistants are chiefly to be found in the drapery trade. Age of entering is usually 14 to 16. In the better class shops a premium of from £20 to £30 is often paid. After three years an assistant receives from £12 to £20 a year indoors, rising in the first-class shops to £70, and, in the case of buyers and heads of departments, to £150 a year. A commission on sales is also given in many shops. The hours are long and the work tiring, and, on the whole, the average wages are less than in other occupations.

Teaching. High-school teachers undergo a long and expensive training, usually taking a University degree. Salaries of assistants in a public school are from £50 to £80, with board and residence. Non-resident teachers from £80. In a large private school senior assistants may rise to £140 per annum. Head mistresses of high schools are paid from £180 to £700 a year.

Kindergarten teachers should spend from two to three years in a training college which prepares them for the National Froebel Union Examinations. For teachers so qualified, salaries range from £50 to £100 a year.

In Elementary Schools the training of the women teachers is on the same lines as that of the men. [See page 164.] All certificated teachers pay into a superannuation fund, and are entitled to a pension of £40. This profession is one of the few which are not overstocked.

THE BEGINNING OF ENGLISH POETRY

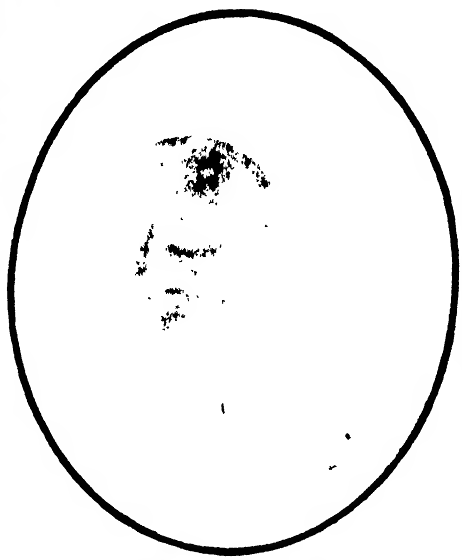
A Short Study of Geoffrey Chaucer and his Work, with an Outline of the Chief Mediæval Poets down to Wyatt and Surrey

By J. A. HAMMERTON

IF one were to begin the study of poetry with the works of GEOFFREY CHAUCER, it is doubtful whether one's progress would be immediate and sustained. For the study of Chaucer requires of the student some degree of cultured love for poetry, which is not so necessary to the immediate enjoyment of Shakespeare or Tennyson.

We mean by this that the reader who as yet has no pretensions to a cultivated literary taste may take up a play of Shakespeare's, a poem of Tennyson's, and fall forthwith under the spell of tho poet's music, his imagination, his wisdom, his humanity, as both of these great geniuses are articulate to us in our daily speech.

But not so with Chaucer and the writers of the later mediæval period. While the body of the language in which Chaucer wrote is the essential English with which we are all familiar, it is different in so many little ways that the reader never quite accepts it as his own tongue, but always finds in it a quaint and somewhat foreign flavour. For this very reason, however, there is the more need that we should familiarise ourselves with the English of Chaucer, as it is with him that our language first attains to classic distinction.



GEOFFREY CHAUCER
After Occleve's portrait

What Chaucer did for English. Some critics, more hasty than wise have condemned Chaucer for introducing so many French words into our vocabulary; and while this complaint may seem at first glance to be capable of ready proof, we have to remember that in Chaucer's day the rude and vigorous Anglo-Saxon speech of the common people had absorbed from the Norman-French of the aristocracy numerous words and idioms not yet quite assimilated, but later to be so, and vastly to enhance the beauty and expressiveness of the language; so that Chaucer was no affected writer, but one true to the speech of his day, which we know as "Middle English." While Chaucer sounds "quaint" to us, he was doubtless as clear and unaffected to his contemporaries as Tennyson to his, clearer than most of our present day poets. Indeed, as Lowell says very pithily: "He found our language lumpish, stiff, unwilling, too apt to speak Saxonly in grouty monosyllables, but left it enriched with the longer measure of the Italian and Provençal poets. He reconciled, in the harmony of his verse, the English bluntness with the dignity and elegance of the less homely Southern speech."

The Need to Read Chaucer's English. We must be at the little pains necessary to the proper understanding of Chaucer's language before we begin to read him, and under no circumstances are we to waste our time on any of those numerous works in which his writings have been "adapted into modern English." Not even Dryden, in his fine version, could help losing much of that Chaucerian simplicity and charm which can be found only in the original, and the trouble of qualifying ourselves for the understanding of that is so slight, that there is no excuse for reading Chaucer in any but his own text, which we have best in the edition so thoroughly edited by Professor Skeat, and indispensable to every student.

Russell Lowell's important essay on Chaucer (in "My Study Windows," of which there are several editions at one shilling) should also be read carefully before proceeding with the study of the poet. Here we can only submit a few rules which will enable the ordinary reader to turn at once to Chaucer with the certainty of finding him surprisingly easy to understand, especially if one has already attempted to read him without knowledge of the principles of metre which he recognised, and which, by the way, are substantially the principles of modern French poetry.

How to Read Chaucer. First of all, we must note that numerous Old French words, since modified in spelling and pronunciation, retained in Chaucer's time a closer likeness to their originals, being in many cases quite un-

altered; for example, "chamber" is chaumbre, "error" is errour, "authority" is auctoritee, and so forth. Then all words ending in "e" have to be read as though this letter formed a separate syllable, except when the word immediately following begins with a vowel, or sometimes when it begins with an "h." Professor Skeat instructs us to sound the final "e" also when it occurs at the end of a line; but, while we cannot question Skeat's authority, it seems to us that if we strictly observe this rule we bring ruin on many lines of Chaucer, which are thus, though written in the iambic pentameter, forced to carry twelve syllables instead of ten or eleven, and crowd his poetry with many needless feminine rhymes. Despite Lowell's belief that there is no imperfect line in Chaucer, it is tolerably certain that even the rule of accenting the "e" was not always observed by the poet when the metre of his verse did not require it. The medial "e" is also sounded as a rule, and thus certain words ending in "ed" or "es" take a syllable more than they require in our modern speech.

Illustrations of Chaucer's Verse. What we have learnt of rhythm in our previous study should enable us to read the lines of Chaucer with that metrical movement the poet meant them to have, and it only remains to add, before giving illustrations, that many of his verbs retain the old German "en," while the past participle has the "y" or "i" prefix, which in Middle English took the place of the old "ge." In the following four lines several of these peculiarities are illustrated:

"Why nil the leoun comen or the bere,
That I mighte onés mete him with this spere?
Thus seyn thise yongé folk, and up they kille
Those hertés wilde, and han hem at hir wille."

It seems to us a distinct weakening of these verses to make each end with a double rhyme, but Dr. Skeat is an unassailable authority on accentuation. The following illustrates the use of the final "ed" and the prefix "y":

"That ever was y-forméd by nature;"

while here is a line that goes against nearly all these rules:

"And liv-ed in joy-e y-nogh; what wold-e mor-e?"

It is possible to make no less than thirteen syllables out of that line as we have marked it; but that is obviously wrong. If we accentuate it according to the rule of the iambic pentameter, in which the poem is written, it reads smoothly thus:

"Ănd lived ĭn jōye ȳ-nōgh; whăt wōldĕ mōre?"

For the general student who is making no effort to become a specialist in Chaucerian or mediæval literature the method we have indicated appears the simplest to follow in scanning Chaucer's verse, and whether it be right or wrong need not trouble him greatly, as it will enable him to enjoy to the full some of the grandest poetry in our language. But, even so, we do not think it wise that anyone should make his first acquaintance with English poetry by reading Chaucer, and we are only dealing with him at this stage as [illegible] by the historical sequence we are observing in our survey. Rather let one's taste for poetry be ripened some little way by acquaintance with Shakespeare or the more modern writers before seriously taking up Chaucer; but, be assured, that Chaucer, once taken up as a task, will be continued as a pleasure.

Chaucer's Characteristics. There is, indeed, no poet more human than Geoffrey Chaucer, hardly one with whom a reader would feel more willing to have had personal acquaintance. The intense humanity of the poet comes out so inevitably in everything he wrote—although his person is never obtruded in any unnecessarily egoistic fashion—his sympathy with his fellows, his delight in Nature's ways, his jovial humour, his reverence, his occasional ribaldry and his sorrows for his follies—all these qualities serve to make his a most lovable personality. In one word, he is a *man*, with some of the failings of his kind and many of its virtues. Lowell refers to him as "a truly epic poet, without knowing it." Although we find in his poems occasional evidence of "absolute dramatic inspiration," which, *were it continuous instead of occasional*, would carry him into the highest rank of the world's great poets, it does seem to us that his inspiration is at least sufficiently egoistic to warrant our regarding him as a narrative poet.

Chaucer's works have been parcelled out into three sections: known as the French period, the Italian and the English. As this seems a somewhat artificial procedure, suggested, perhaps, by the pedantic vanity of some critics rather than by any decisive evidence of his writings, we shall not follow it, but endeavour to state as briefly as possible the few facts with which the young student ought to be familiar.

Influence of Continental Literature. Although a great creative artist, Chaucer's genius was awakened by the influence of Continental literature with which, as a scholar, he early made acquaintance, the French poets and the Italian poets and story-tellers being familiar to him in the original, and largely drawn upon by him for his material. His heaviest debts are to Boccaccio, his great Italian contemporary, whom, as well as Petrarch, he is popularly supposed, on very slender evidence, to have met during a diplomatic mission to Italy. It is also probable that Dante's "Divina Commedia" had considerable influence on him, while his verse-form was derived from the *trouvères* of France, who for more than two hundred years before him had been composing those epic poems which the *jongleurs* carried about in manuscript or in memory and recited in castle halls. Yet, with all his borrowings, and even when he seemed only to have translated, Chaucer so wonderfully transmuted by his genius the material wherewith he worked that it was *re*-created, as is the case with all great artists. Boccaccio himself, from whose "Decameron" Chaucer drew so much for his "Canterbury Tales," and whose "Filostrato" he so closely follows in "Troilus and Criseyde," took his

stories from the popular mediæval fiction of his time, and gave them classical form. But the artist mind of Chaucer is well illustrated in "The Canterbury Tales," where every personage tells a tale that is suited to the teller's character, taste, or condition of life, whereas there is no such dramatic fitness observed in the "Decameron."

"The Canterbury Tales." This, of course, is the work with which the name of Chaucer is always associated in the popular mind. But great though it is in many ways, and absolutely characteristic of the poet, as a composite whole it is doubtful if it can be placed before his "Troilus." The plan of the book is so familiar that it is not necessary to do more than outline it in a very few words. A company of pilgrims, journeying to the shrine of Thomas à Becket at Canterbury, foregather in Southwark at the Tabard Inn, where the poet, himself supposed to be starting on a pilgrimage to Canterbury, meets them and proposes to make one of the company. The landlord of the Tabard also offers to join the party and to act as guide. It is he who suggests that in order to beguile the tedium of the journey each pilgrim should undertake to tell two stories, both going and returning, and that the teller of the story which is voted the best will, on the return to the Tabard, be entertained to supper at the common cost of his or her fellow pilgrims: for the company is of both sexes.

Although Chaucer did not set himself the task of relating every one of these stories told by the pilgrims, who, including the poet, numbered thirty-three, the twenty-four tales and prologues of which the work consists form only a fragment of his design; but a glorious fragment, which for nearly two hundred years remained the unequalled gem of English literature.

The Pilgrims. Surely there never was a merrier company of pilgrims than that which set out from the Tabard, with Harry Baily to guide them, on a journey that had little of penance in it. In the Prologue, which is the very acme of Chaucer's achievement, the characters of the different persons are so vividly drawn that they live again for us in the very atmosphere of the Middle Ages. The tales themselves vary in merit, but the "Knight's Tale" is generally regarded as the finest of the series, and the "Miller's Tale" is perhaps the coarsest. We have no space here to discuss the ethics of the poet's reasoning in his apology for including certain stories more racy than polite:

"And ther-fore every gentil wight I preye,
For goddes love, deemeth nat that I seye
Of evel entente, but that I moot reherce
Hir tales alle, be they bettre or werse,
Or elles falsen som of my matere.
And therfore, who-so list it nat y-here,
Turne over the leef, and chese another tale."

This does seem true enough from the artistic point of view, and from that of historical truth it is equally cogent, for it has to be borne in mind that the poet reflected in his mirror the manners of a rude age, despite the fact that it was the time "when knighthood was in flower." We see no reason, therefore, to suppose he wrote thus "with his tongue in his cheek," as some critics have suggested. As we have already indicated, however, "Troilus and Criseyde" may be considered the fine flower of Chaucer's genius; one of the most perfect works of poetry in the English language.

Where to Begin. But it is neither with "The Canterbury Tales," nor yet with this classic story of Priam's son and the false Cressida (which Shakespeare also took for one of his plays), that we would have the young reader first taste of Chaucer's poetry. Rather begin with those exquisite little poems comprising "The Legend of Good Women," in which he relates the tragic love-stories of Cleopatra, Thisbe, Dido, Ariadne, and other classic heroines. These are each of a length sufficient to attract the reader who is not yet familiar with the poet's manner and to prepare him for the longer works.

It is a safe assertion that the reader who has borne Chaucer company through only two or three of these poems will require no counsel to cultivate acquaintance with the writings of this merry, wise and gentle poet, who was at once a scholar, a lover of books and ancient lore, but not the less a lusty Englishman, who rejoiced in the world out of doors and all the ways of Nature.

"And, as for me, though that my wit be lyte,
On bokes for to rede I me delyte,
And in myn herte have hem in reverence;
And to hem yeve swich lust and swich credence,
That ther is wel unethe game noon,
That from my bokes make me to goon,
But hit be other up-on the haly-day,
Or elles in the joly tyme of May;
Whan that I here the smale foules singe,
And that the floures ginne for to springe,
Farwell my studie, as lasting that sesoun!"

Chaucer's Life. Chaucer was the son of a London vintner, and is believed to have been born about the year 1340. He had the education of a gentleman, and has been claimed as a scholar of both Oxford and Cambridge, but there is no evidence of his having attended either university. He was a great favourite at the court of Edward III., and was a follower of John of Gaunt, "time-honoured Lancaster," to whom, by the poet's marriage with Philippa de Rouet, Chaucer later became brother-in-law. As a youth he had in France borne arms for Edward, and was for a time held prisoner of war. During a considerable part of his life he enjoyed prosperity, holding various official posts, and being, as we have heard, employed on diplomatic missions; but he experienced reverses of fortune during the early years of the reign of Richard II., and although he regained the favour of that monarch, as well as the regard of his successor, Henry IV., son of his patron, the Duke of Lancaster, the later period of his career seems to have been somewhat troubled. But this did not dim his genius, for his poetry was at its very best in the autumn of his days. He died in the year 1400, and his writings, which

had circulated in manuscript copies only during his own life, were first printed by Caxton, who issued an edition of "The Canterbury Tales" about the year 1475, while the earliest complete edition of his works was that by Godfrey in 1512.

So commanding is the figure of Geoffrey Chaucer in English mediæval literature that more than two hundred years have to pass before another stands beside him on the same plane, and even then it might be argued that it is a relation of master and disciple, for Spenser acknowledged Chaucer as his master. But they have really little in common, and there is more reason for believing Spenser's masters to have been the Italians, Ariosto and Tasso. Thus the poets who come between Chaucer and Spenser are not of any great account to the general reader, though several of them are eminently worthy of study by those who aim at a more intimate knowledge of our literature.

John Gower. Chaucer had in John Gower a fellow-poet and a friend who was only secondary in importance because it was his fate to live under the shadow cast by his great contemporary. Not that Gower had else been a great writer, for his limitations are so well defined that he is one of the authors over whom there is small reason for critics to disagree. He may be described as a man of great talent, ripe scholarship, character, but not a man of genius. While in sheer craftsmanship he was even Chaucer's superior, and perhaps in scholarship also, he lacked that divine fire which lifts the genius above considerations of craft. Gower wrote three large works, in French, Latin and English respectively. The first is no longer in existence, while the second, which is composed in Latin elegiac verse, describes the Wat Tyler rising, and thus has some value in the eyes of the historian, though it possesses none for the reader of poetry. His English work is his greatest, and has been reprinted in popular form within recent years, an edition being issued under the editorship of the late Professor Henry Morley. It is entitled "Confessio Amantis" (A Lover's Confession), and is most tedious reading. Its interest is mainly for the philologist, so it may very well be passed over by the general reader. Gower, who came of good family, died in 1408, and his effigy may still be seen on his tomb in St. Saviour's Church, Southwark, where he is shown with his head pillowed by his three ponderous works.

JOHN GOWER

John Barbour. Also contemporary with Chaucer and Gower was John Barbour, the first great Scottish poet, whose chief work, "The Bruce," is a national epic written in octosyllabic verse, remarkably spirited, full of movement, observation, and accepted by authorities as historically accurate; so that Barbour has the double value of historian and poet. The original is perhaps a little more difficult to read than Chaucer, whom Barbour resembles in his love of nature; but as the historical value of the work is at least equal to its poetical, there need be less hesitation in making its acquaintance in a modernised version. Most collections of Scottish poetry give considerable space to lengthy passages from "The Bruce." We may quote a few lines from the original to illustrate its style. They occur in the description of the launching of Bruce's galleys, with his little army of three hundred men, from the island of Arran, to cross the Firth of Clyde to Turnberry:

"This wes in Ver,[1] quhen wynter tyde,
With his blastis hidwyus[2] to byde
Was our drywyn,[3] and birdys smale,
As turturis[4] and the nychtyngale,
Begouth rycht sairely to syng,
And for to mak in thair singyng
Swete notis, and sownys ser,
And melodys pleasand to her."

Barbour, who was born in 1316, and died in 1375, was Archdeacon of Aberdeen for about forty years, and made several journeys through England and France, chiefly, it has been thought, to collect material for his books.

The Fifteenth Century. It is strange that after the splendid start which Chaucer had given to our literature, the fifteenth century should have been so barren of great writers, although in the latter part of that century Caxton introduced printing into the country. That English poets of the calibre of Thomas Occleve, who was thirty years old at the time of Chaucer's death; John Lydgate, a dull imitator of Chaucer; and Stephen Hawes, a writer of prolix allegories; and Henry the Minstrel, in Scotland, could achieve popularity, is sufficient proof of the poverty of the period in works of imagination. But King James I. of Scotland made good use of his long imprisonment in England by writing many poems, and notably "The King's Quhair" (Bo k), which are models of good English,

[1] Spring. [2] Bitter blasts. [3] Overpast. [4] Turtle-dove.

graceful in style, and at times approach close to Chaucer both in music and imagination. The student should read, in this connection, Washington Irving's fine essay, "A Royal Poet," in the "Sketch Book." Then JOHN SKELTON cuts no contemptible figure in fifteenth century literature, despite the adverse criticism to which he has always been subjected. "Beastly Skelton" is how Pope dismisses him, and Puttenham in his "Arte of English Poesie"—which, published in 1589, was one of the critical works that accompanied the Elizabethan literary revival—says of him: "Being indeed but a rude rayling rimer, and all his doings ridiculous; he used short distances and short measures, pleasing only the popular eare." But, all this notwithstanding, Skelton was our English Rabelais, with a good deal of the Frenchman's learning, his unrestrained delight in word-play, something of his satire, much of his coarseness and his joviality. Still, he is not for the average reader. Skelton, like WILLIAM DUNBAR, the Scots poet, who belongs equally to the fourteenth and fifteenth centuries, was also a priest; but Dunbar, on the whole, shows a better balanced character, and although he can rival his contemporary in coarseness when he cares —which is much too often—he displays public spirit in his satires, grace and wit in his allegories, and is at times capable of real pathos. Born about 1460-5, most of his life was spent at the Scottish court, and his most famous poem, "The Thrissill and the Rois" (The Thistle and the Rose), was an allegory on the marriage of James IV. with Margaret, eldest daughter of Henry VII. It is supposed that he accompanied the ambassadors who went to England to arrange the marriage. Dunbar died about 1522, in which year was born GAWIN DOUGLAS, Archbishop of Dunkeld, who wrote some animated poems, especially "The Palice of Honour," and rendered the "Æneid" into Lowland Scots, this being the first translation of a Latin classic published in Britain.

A Twilight of Genius. But unless we were to include Sir THOMAS MORE (b. 1480, d. 1535) among the poets who belong to the dim twilight of the Middle Age, though coming so near to the bright sunrise of the Elizabethan renaissance, there is hardly any name until we come to Sidney or Spenser that can be said to have much significance for the general reader. And More's "Utopia," written in Latin, though poetical in the quality of its imagination, is not so in form, so that it would be a deliberate straining of words to include him with the poets, especially as he must receive our consideration when we come to study the beginning of English prose. It is difficult to imagine him as the friend of JOHN HEYWOOD (b. 1506; d. 1565), a poor rhymer who is only interesting to the student as being one of the first to introduce into the drama subjects drawn from everyday life, and thus to hasten the end of the old "morality" plays. A writer more lacking in every literary grace it would be hard to find, and the fact that he was the favourite jester of Henry VIII. indicates the low standard of taste which prevailed at that time. Sir Thomas More and he may have been friends chiefly because they were both ardent Catholics. Sir Thomas Wyatt and his friend Henry, Earl of Surrey, were, however, poets whose works are worthy of passing attention, and who, as the originators of what we may call "amatory" verse in English, will always call for some notice. The ordinary reader may be content to make their acquaintance in anthologies, and will find as much of their verse as he need read in "The Surrey and Wyatt Anthology" (Oxford Press, 2*s.* 6*d.*).

Wyatt and Surrey. Sir THOMAS WYATT (b. 1503; d. 1542) wrote many graceful sonnets and lyrical poems characterised by a grave courtliness rather than the light touch of the true love-poet, while the EARL OF SURREY (b. 1517; d. 1547), though of a livelier temperament and a true lover, did not excel him in the quality of his verses. Wyatt introduced the sonnet stanza, Terza Rima, and blank verse into England from Italy, and these first two forms we shall illustrate further on. Surrey was the first of English poets to write any considerable poem in blank verse, into which he translated books II. and IV. of Virgil's "Æneid."

With Wyatt and Surrey, which latter the great French critic H. A. Taine, in his "History of English Literature," describes as "an English Petrarch," our language had at length acquired greater literary possibilities than it had before possessed: "Those who have ideas now possess an instrument capable of expressing them," says Taine, and to what purpose this instrument was used we shall proceed to inquire.

EXAMPLES OF ENGLISH METRES (see page 306).

1. *Trochaic.*
   Fōr thĕ ĕarth hĕ drēw ă strāight līne
2. *Iambic pentameter, blank verse.*
   Thĭs rōyăl thrōne ŏf kings, thĭs scēptĕr'd isle.
3. *The same, opening with trochee.*
   Măn ĭs ă shĭp thăt sāils wĭth ādvĕrse winds.
4. *Trochaic.*
   Hēnrȳ, tōō, hăth hēre hĭs pārt.
5. The line
   "Void of all succour and needful *com*fort" is wrong, because, the accent falling on the last syllable but one, there should be eleven syllables. It could be re-arranged thus:
   "Of succour and all needful comfort void," or made to scan by putting a second "of" before "needful."
6. *Dactylic.*
   Fārewĕll tŏ ōthĕrs, bŭt nēvĕr wĕ pārt.
7. *Anapæstic.*
   Lĭke thĕ lēāves ŏf thĕ fōrĕst whĕn sŭmmĕr ĭs grēēn.

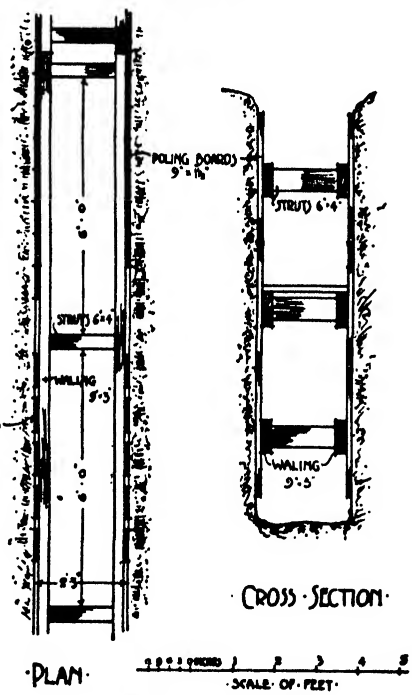
LAYING THE FOUNDATIONS

The Work of the Excavator. Soils and their Bearing Power. Natural and Artificial Foundations. Piling and Underpinning

By Professor R. ELSEY SMITH

Top Soil and General Levelling. In excavating a site it is usual first to remove any turf, setting it aside for relaying or sale. Turfs are usually three feet long, one foot wide, and are rolled. Gravel paths, flags, etc., may sometimes be similarly taken up and set aside. It is usual also to take up and set aside the top layer of earth if suitable for garden purposes. After this has been done the site must be levelled to the depths shown in the drawings.

In some cases a uniform level is required throughout. In other cases the level varies in different parts of the site. Hollows may require filling up, and in such cases the best of the material is selected for this purpose. The spoil, when excavated, increases considerably in bulk. Increase varies with different soils, but does not often exceed 20 per cent. Such material, if filled in again, gradually consolidates and contracts. To assist the process it is usual to water it liberally, and ram it. The settlement due to consolidation is usually not less than one inch in one foot, and may exceed this proportion considerably. Any material useful for building purposes — *e.g.* good gravel or sand free from loam or clay—may be put aside and used for building by arrangement with the owner.



4. TIMBERING TO A TRENCH

Trenches. When the general levels have been reached, any additional excavation for cellars, vaults, basements, etc., are made as well as trenches to receive the foundation and drains. Drain excavations are often deferred until the carcase of the building has been completed. All the excavations are sunk to the depths shown in the drawings. The trench required to take the concrete under a 9-inch brick wall is not less than 2 ft. 2 in. wide, just sufficient to allow a man to work in it; but he cannot throw out the spoil from beyond a depth of six feet, and if the excavation exceeds this, a stage must be provided on which he throws the spoil and from which it is thrown out, increasing the labour and the cost. An extra stage is required for every extra six feet in depth. In a ten-hours' day a good excavator can dig and throw into barrows eight to ten cubic yards of common ground, five to six cubic yards of stiff clay or firm gravel, and if hard ground, where the pick is used, three to five cubic yards. For deep drains tunnelling may have to be undertaken. This is done by sinking pits at convenient intervals and excavating short tunnels from one to the other. The width is determined by the nature of the work required. The height must be sufficient for a man to work in, and the sides are usually made to slope in towards the top of the tunnel.

In moist and wet soils water is liable to soak into excavations, especially in wet weather. All water must be got rid of by baling if the quantity is small, or by pumping if it is large. It should be constantly kept under, as it softens and deteriorates the surface of the trench.

Bearing Power of Soils. Trenches that have reached the depths shown upon the drawings should have the bottoms carefully tested to see that the stratum of soil is of a character suited to carry the load to be placed on it. In ordinary cases this may be done by driving in a crowbar to test the solidity of the ground, and on sites previously occupied an examination must be made for old and disused drains, wells, and cesspools, which, if built over, might collapse. Such drains or cesspools should be cleared away. Any old foundations should be grubbed up and cavities filled with concrete if walls or piers are to stand over them. Otherwise they should be filled with hard dry brick rubbish. Where the bearing capacity of the ground requires to be carefully tested, a strong platform with legs framed to it at the four corners may be used. If 6 in. by 6 in. legs are used, the area of the four together should equal one foot

superficial, and the table can be loaded with any convenient heavy material. The ground is carefully levelled and the table placed in position.

The level of each corner accurately taken in relation to some fixed datum, the load is applied gradually, evenly, and without shock; the levels are taken again from time to time, and the load is increased until variation is noticed. From one-fifth to one-half of the load required to produce settlement is taken as the safe load. If the load to be carried exceeds the safe load, a stronger stratum must be sought, or the weight per foot reduced by an increase of the area of the bearing surface.

TABLE OF BEARING POWER OF SOILS*

Material.	Bearing power in tons per square foot.	
	Min.	Max.
Rock, hard	25	30
„ soft	5	10
Clay in thick beds always dry	4	6
Clay in thick beds moderately dry ...	2	4
Clay, soft	1	2
Gravel and coarse sand well cemented	8	10
Sand, compact and well cemented ...	4	6
„ clean and dry	2	4
Quicksand, alluvial soils	½	1

Small sections of soft ground are sometimes found in trenches otherwise satisfactory. These may often be dug out to a sound bottom and filled with concrete without deepening the whole trench. On a sloping site it may be necessary to introduce steps into the trenches, but in all cases the bottom of the trench for foundations should be kept level; those for drains may be excavated to conform to the fall in the drain.

The concrete should be laid in the trench as soon as possible after opening to protect the foundation from the weather.

Timbering. Where it is necessary to carry excavations perpendicularly or nearly so, as in trenches or for cellars, means must be taken to support temporarily the face of the earth which is liable to crumble away or be forced into the trench. In some shallow excavations this precaution is not necessary if the trench is to be open for a short time only, but in loose soils even shallow trenches, and in all soils deep trenches, must be protected. This is done by *timbering*.

The nature of the work depends on the character of the soil. Good soils are usually natural or *virgin* soils that have not been disturbed and include dry clay. Moderate soils include ground that has been filled in (termed *made ground*), loose gravel, while treacherous soils include sand, wet clay, all water-logged soils, and even ordinarily good soils if trenches are dug near existing excavations.

The materials used for timbering are *poling boards*—*i.e.* short lengths of board usually 9 in. by 1½ in. and 3 ft. long, but sometimes longer, placed vertically against the sides; *waling pieces*, which are horizontal timbers usually 9 in. by 3 in., placed about the centre of the poling boards, and *struts* to keep the whole in position.

Methods in Different Soils. In good soils continuous timbering may not be required if the trench is not very deep or wide. In such cases a pair of poling boards are placed against each face of the excavation opposite each other. The strut is cut about half an inch or three-quarters of an inch longer than the distance between the boards inserted between them and forced into a horizontal position with the help of a heavy hammer. Pairs of boards thus fixed may be placed at intervals of about six feet. If placed closer they impede the excavator in his digging, and if they do not suffice to keep the sides intact, a different system must be adopted. The poling boards are then placed with only short intervals between them, or in some soils actually touching. Strong horizontal timbers termed *waling pieces* are placed in front of them at about the centre of the height and secured with struts, as already described. In a long trench the waling pieces have to be joined and a strut is placed close to the end of each length [4], with intermediate ones at intervals of six feet. Such timbering is put into position and secured as soon as the trench is of sufficient depth—about three feet—and before any further ground is excavated. As the digging proceeds in deep trenches, similar timbering is placed below the first in successive stages as required, care being taken to keep the struts vertically below those above.

In some soils the vertical face cannot be relied upon to stand safely even while a three foot trench is being dug. In such cases, in place of vertical poling boards, horizontal planks (termed sheetings) are placed in position as soon as from nine inches to twelve inches in depth has been excavated and temporarily strutted. Then, when another layer is removed, a second board is placed below the first and strutted, and so on, until a depth of about three feet has been reached. Vertical walings are then placed in front of the boards and secured with struts, the temporary ones being afterwards removed. A greater depth may then be got out and protected in the same way. The platforms or stages required in deep trenches for throwing out the spoil may be carried on the waling pieces.

Water-logged Ground. In water-logged ground special precautions must be taken, and heavy and very sound timber used. Longer boards, usually 11 in. by 3 in. and up to eight feet long, are used in place of poling boards, and are termed *runners* [5]. The feet are cut to an inclined chisel edge and in strong ground shod with iron, as in sheet piling. In fixing after ground is excavated as far as is safe, guide runners, about ten feet apart, are driven in by mallets and strong waling pieces fixed and strutted. Other runners are inserted and driven in until a continuous wall is formed. Excavation then proceeds until within about a foot of the bottom of the runners, when they are driven further down, additional walings inserted, and the struts increased with the depth.

In a deep trench, if a second set of runners (or

* Ira O. Baker, C.E., in "Treatise on Masonry Construction."

more) is required, they are not set under the upper ones, but within them, so that the width of the trench is narrowed, and allowance for this must be made in setting out the upper trench. The heads of the lower runners must not be driven deeper than about 12 inches above the feet of the upper runners.

Tunnelling. Where tunnelling is employed similar precautions must be taken. A shaft is sunk to the required depth, the tunnel is worked in from the face, a commencement is made at the head, and as soon as the roof shows any signs of insecurity poling boards are driven in close against the roof and supported by a cross-beam or *header*, the ends of which are strutted from the floor, the feet of the struts being let into it to prevent accidental disturbance

Poling boards can be driven in behind the struts [6]. Excavation then continues until another set of poling boards and frame can be inserted. In very bad or wet soil a more elaborate plan is necessary. The poling boards are longer and directly supported by squared timbers arranged as a frame. These in turn are supported by horizontal pieces which are themselves strutted by a very strong frame, often including a sill to take the feet of the struts, which must be sunk below the floor level. Notches are cut in the heads and sills and the struts fitted to them, but large spikes are sometimes used for increased security.

Large excavations also require to have the sides timbered; the system is generally similar, but the walings are usually heavier, and the struts are formed of large timbers and are tightened with folding wedges [7]. In excavations too wide for strutting the walings require to be supported by shores [see SHORING] placed at intervals along the sides of the excavation.

Natural Foundations. The natural soil on which a building rests has to bear the whole burden of the superstructure, which must be disposed so as not to cast too heavy a load on any part of it. Every wall is required by the London Building Act and by most Local Acts to have footings [see BRICKLAYING] equal in width to twice the thickness of the wall, and in addition, with a few exceptions, to have a slab of concrete under it at least eight inches wider than the footings. For fairly good soils and with ordinary buildings of moderate height this secures a sufficient distribution of the load for security.

In the case of buildings in which different parts are unequally loaded and where heavy loads are carried by detached piers or stanchions, it is important not only that the load should not exceed the bearing capacity of the soil, but that the pressure upon it should be as nearly as possible equal at all points; so that should any settlement occur in the foundations, it will be uniform, otherwise the more heavily laden parts will be the most liable to sink, producing cracks in the superstructure.

It is therefore necessary to calculate the actual weight of materials supported by each square foot of brick or stone in the general walls, as well as in the piers and to regulate the area of the concrete under them so as to produce a uniform pressure. In this calculation must be included the proportion of every floor area and of the roof carried by the wall or pier, including the load it is intended to carry.

For domestic buildings an allowance of 1 cwt. per foot super of floor, including the load, is an ample allowance, though 1¼ cwt. is often allowed. For public buildings 1½ cwt. per foot super, including the load, is allowed. For warehouses and other special buildings it is necessary to ascertain the actual load to be carried, which is often from 2 cwt. to 3 cwt., and may be as high as 6 cwt. per foot super.

Rock. Of the various soils usually met with in foundations, the strongest is *rock*. This will support any load that is likely to be put upon it, even if not a strong rock, and makes an excellent foundation if it entirely covers the site. Many rocks are apt to hold water in pockets and fissures, and means must be taken to get rid of this by giving the surface a slight inclination and arranging for the discharge of any water that collects.

Any loose or decayed material on the surface must be cleared off, and if the surface is not level the stone must be worked into level beds under the footings and stepped where necessary. Holes and fissures may be levelled up with cement concrete, or, if large and deep, may be arched over in stone or concrete unless they come directly under a heavily loaded pier. Should the rock only extend over part of the site, the remainder being of some less solid material, the foundation is by no means easy to deal with, and great care must be exercised to give a sufficient bearing to the portions of the building on the weaker soil, or an unequal settlement may develop.

Clay. Clay varies greatly, according to its nature and position. The blue London clay forms a first-rate foundation, but is only encountered as a rule at considerable depths. The ordinary yellow clay varies greatly. It will sustain any reasonable load if fairly dry and not subjected to influences that will change its condition. It is essential to carry down excavations below the level at which it is affected by changes of weather and climate, and for safety this may usually be taken at about five feet below the surface. Clay that is liable to be reached by an excess of water becomes soft and plastic, and will squeeze out under pressure, and trenches in clay in particular should be concreted as quickly as possible. There is the further liability on sloping ground that excavations may be opened at a lower level, drain the moisture from the subsoil and so produce subsidence, and in consequence of its liability to change with altering circumstances, the yellow clay should be looked upon as a foundation requiring very cautious handling.

Gravel. Gravel is one of the best foundations after rock. If compact, and where an entire foundation consists of this material, footings may be constructed on it without concrete beneath them. The gravel must not, however, be in a position where it is subject to

erosion by flowing water, or it must be properly protected from such action. Even loose gravel, if confined so that it cannot spread, forms a good basis for building, but a slab of concrete should be used.

Sand. Sand also makes a good foundation if it is confined so that it cannot spread and is protected from erosion. It is practically incompressible, but is easily washed away by running water. If the bottoms of the trenches require to be stepped or if a deeper excavation for cellars is required, care must be taken to prevent the sand in the upper parts from being forced out.

Chalk. Chalk varies considerably in quality and is liable to disintegrate if exposed to the action of the weather. The strata immediately below the top soil are often somewhat loose, but if excavations are carried below the weather line a very good sound foundation is usually reached. There are apt to be fissures and pockets of loose gravel and sand, which if they come under walls or piers should be emptied and filled with concrete, or, if the load is light, they may be covered with a thick slab of concrete. An exposed chalk face should be protected from the action of the weather by a facing of brickwork, stone, or flint.

Quicksand, Alluvial Soils, and Made Ground. Quicksand, alluvial soils, and made ground are all unsatisfactory as foundations. They are compressible, and made ground in particular is liable to contain putrescible material. Circumstances may arise in which buildings must be erected on such foundations, and in all such cases special precautions must be taken. The circumstances of each individual case must be carefully considered as it arises.

Made ground varies much in character. It may be the result of excavations for sand or gravel, which have been replaced by other hard dry material, which, with the lapse of years, attains very fair solidity, or it may be the result of a general raising of the level of a low-lying locality, such as has taken place in parts of the East of London. In the latter case, road sweepings, ashes, etc., are often employed, sometimes in a wet condition, when they will be offensive for a long time, and will never become well solidified. The presence of putrescible matter in the soil may be a source of danger to health, as the ground air under some conditions is drawn into buildings by the action of ordinary fireplaces.

Trial Holes. Before the building is designed, the nature of the soil, unless well known, must be ascertained by sinking square pits or trial holes at various parts of the site, noting the character of the strata pierced and seeing whether their character varies in the different pits. Where a soft stratum occurs above a hard one, it is as a rule desirable to sink the foundations to the harder bed, but where a hard stratum occurs above a soft one, it is often safe to build on the upper one, provided it is possible to leave a considerable thickness of it undisturbed. In such cases much will depend upon the building to be erected, and inquiry as to the circumstances of surrounding buildings must be made and judgment exercised. No hard-and-fast rule can be laid down. A thorough acquaintance with the nature and capabilities of the bearing stratum is not only necessary before the work is started, but should, when heavy loads have to be dealt with, be gained before the footings are designed.

Artificial Foundations. The footings of a wall or pier can seldom be laid on the natural foundation. Almost always some other provision must be made to receive them, and this must vary with the nature of the natural foundation and the load it has to bear. The loads to be carried due to walls and piers respectively having been calculated, the safe load that the natural foundation will sustain and the area of the bearing surface under each may be ascertained and the trenches excavated to the required size. With a good natural foundation, even when heavy loads are to be carried, a thick layer of concrete is the material usually employed. With poor and treacherous soils other methods must be adopted.

Concrete. Concrete is a material which, when first formed, is in a plastic condition, and can be filled into any prepared excavation or mould. Within a few hours it sets into a solid rock-like mass, and within a few days attains a very considerable strength, though its maximum strength is not reached for months. It is composed of some hard substance broken into small pieces termed the *aggregate*, forming the bulk of it, and of a binding material termed the *matrix*. The nature of the *aggregate* varies according to the purpose for which the concrete is to be used. For foundation work and walls nothing better can be had than stone ballast from a river or pit gravel. Shingle for many purposes is suitable, but the stones in it are not "sharp" or angular, as is desirable, and the presence of salt renders the concrete liable to show signs of damp in wet weather or in moist situations. Other substances used are broken stone, clinker, burnt ballast (only permissible if thoroughly vitrified), and broken brick and pottery, which must also be thoroughly burnt. Underburnt bricks or ballast are not suitable. An excellent concrete results from about 25 per cent. of good broken brick with some form of stone aggregate. Whatever the material, it must be broken up to pass some standard. A two-inch ring is very often specified. This secures a solid uniform material without cavities.

Concrete Floors. For concrete floors laid on the solid, similar aggregates may be used. For upper floors, roofs, etc., in fire-resisting structures, lightness is of importance. Coke-breeze and pumice-stone are often employed, and for such purposes should be broken fine enough to pass through a one-inch ring. This is termed fine concrete. For concrete stairs, pavings, etc., the aggregate consists largely of granite chippings.

If the aggregate does not contain sand, sand or some substitute must be added to the extent of about 25 per cent. to 30 per cent. of the total bulk. The object of the sand is to fill up all interstices and to give cohesion. It is essential that the aggregate should be clean, free from all animal and vegetable impurities, and

that the sand should be sharp and free from loam. If loam be present, the sand must be washed. Washing is done in a tub of water. A large circular sieve is used, and with the sand is dipped into water till submerged. It is rotated so that the loam is washed out, and the sand is then thrown out into a heap.

The Matrix. The matrix consists of hydraulic lime or Portland cement [see MATERIALS AND STRUCTURES]. The proportion of matrix to aggregate varies with the nature of the matrix, with the situation of the concrete, and the work it has to do. In the case of lime, if only feebly hydraulic, the proportion should not exceed one of lime to four or five of aggregate. Such concrete is not suitable for use in very large masses or in moist situations. If eminently hydraulic it may be one of lime to seven of aggregate. With cement the proportion may be one of cement to eight or nine of aggregate for concrete walling, and one of cement to five or six of aggregate for wet foundations and for concrete flooring.

Water. The water used must be clean, and it is important that no more should be employed than is necessary for the proper mixing of the ingredients. An excess of water reduces the ultimate strength of the concrete. The method of mixing is as follows: The proportion of matrix and aggregate being fixed by the specification, square frames without tops or bottoms are made [8]; the smaller contains a single unit, say a yard, for the matrix, the larger the corresponding number of units required for the aggregate. If the aggregate is not formed with a single material, but has, *e.g.*, a certain proportion of brick mixed with it, this is most usually incorporated before the mixing of concrete itself begins, but if necessary three or more frames may be employed, each proportioned in capacity to the amount of material to be used.

A close-boarded floor is provided as close to the spot where the concrete is to be used as possible, or a floor of sheet iron is sometimes used. The frames are placed on it, filled up level to the top (but not heaped up), and then removed. The aggregate is spread out, the matrix spread evenly over it, and the two thoroughly mixed by being twice turned over with shovels, dry—*i.e.* without any water. They are finally turned over with the addition of the necessary water, forming concrete, which is at once conveyed to the spot where it is to be deposited. In the case of trenches for foundation work, it may sometimes be thrown in by shovels direct. More usually it is filled into barrows, wheeled and tipped in. This must not be done from any great height, or the larger stones will collect at the bottom and the mass not be homogeneous.

Depth. If the depth of concrete is not great, say, 12 in. to 18 in., the full depth may be at once placed in the trench, in which stakes are driven and carefully levelled, marking the top of the concrete, which is spread and levelled by a labourer standing in the trench as soon as it is deposited, and should not afterwards be disturbed. Where a deep bed of concrete is required, it is usual to deposit it in successive layers of about 12 in. at a time. In the case of deep trenches the concrete must be lowered in bags or in barrows to a stage from which it can be tipped. Concrete should not be deposited in trenches containing water, which is apt to wash out the cement, leaving the lower part of the concrete poor. Water, however, does not interfere with the setting of concrete mixed with eminently hydraulic lime or cement. If used under water, it must be lowered in sacks and the surface protected till setting occurs.

Where a horizontal bed cannot be completed without interruption, it is usual to form the end with a V-shaped recess on plan [9] to give a vertical key to the next layer of concrete, and if this is not put in till the first is dry, the joint should be well wetted before the new concrete is deposited. Where successive layers are used, care must be taken that no mould from the trench or dust or rubbish is left on the upper surface of the old bed before the new concrete is deposited. The top surface of the final layer is levelled and smoothed over to receive the brick footings.

Concrete over Site. The concrete which is usually spread over the whole site within the walls, and which may form the bed for solid floors, or may be some distance below boarded floors, is usually cement concrete not less than six inches thick, spread uniformly, and with the upper surface smoothed over with a spade or shovel. Upper floors are filled in on a centre. This may be a close-boarded, flat, wooden centre [see CENTREING], or may consist of terra cotta lintels, iron sheets, etc., which remain as part of the floor. When concrete is used in this way in combination with iron or steel joists, it must be well rammed around the flanges.

Concrete may also be filled into moulds, and when set used as blocks for building or as lintels, channels, etc. Concrete walling may also be cast in position. In this construction the space to be occupied by the wall is enclosed with close boarding fixed to upright posts, well tied and strutted, and the concrete is filled in in layers of about twelve inches at a time [12]. This is often done for retaining walls, but buildings of concrete have even been constructed in this manner.

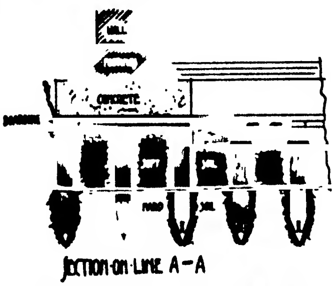
In the case of concrete masses intended to receive heavy machinery provision must be made for securing the machinery. This may be done by building in iron or steel girders, to which they are bolted, or by building in holding-down bolts with anchor plates [10], and in all such cases templates giving exact position of bolts must be obtained from the firm supplying the machinery. Pieces of timber dovetailed in section are sometimes built into concrete beds standing above the surface of the concrete for lighter machinery [11], and are useful where machines must be shifted [see also FIRE AND FERRO-CONCRETE].

Foundations on Compressible Soils. Such foundations, even for heavy buildings, are sometimes inevitable, and in such cases means must be taken to render the natural foundation capable of supporting the superincumbent load. The circumstances are so varied that we cannot deal exhaustively with every

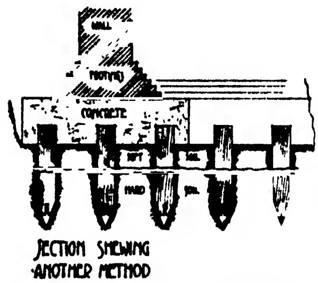
case, but must refer to the general methods of dealing with this difficult problem. Such foundations are inevitably costly, but the cost must be faced.

The method will depend upon the nature of the site. If the compressible stratum overlies a good solid stratum, but the latter is so deep that the cost of taking down the walls of the building is prohibitive, it may nevertheless be possible to take down piers of concrete or masonry to the lower level at short intervals and to throw arches or girders from pier to pier to carry the walls. This is only possible when the soft stratum is of a character that will permit of shafts being sunk, and cannot be employed for anything in the nature of quicksand or water-logged strata.

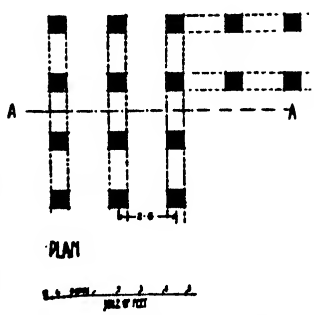
The area of such piers must be proportioned to the loads to be carried. The bottom must be carried well into the solid stratum and the piers carefully constructed. Their spacing must depend upon the nature of the building to be supported, but they will not be, as a rule, more than ten feet apart in the clear. Iron screw-piles may sometimes be employed in such circumstances spaced at greater intervals and the tops connected by heavy girders. [For description of screw-piles see CIVIL ENGINEERING.]



13. PILING WITH TIMBER PLATFORM



14. PILING WITH CONCRETE PLATFORM



15. PLAN OF PILES UNDER A WALL AND CROSS-WALL

Piling. When the soft stratum is very deep or very treacherous, say 30 ft. or 40 ft., the system of piers is not suitable, and in such cases long piles may be driven through the treacherous ground into the solid stratum below. [For piles and pile-driving see CIVIL ENGINEERING.] In America, where buildings of great height are erected, it is frequently the custom to drive in piles two to three feet apart centre to centre in rows spaced at intervals of about 2 ft. 6 in. centre to centre over the entire surface of the site. In most cases it may suffice to drive two or three rows of piles under the lines of the main walls [15]. Care must be taken to cut off the tops at such a level as to be below that at which water stands, for if the tops are dry, they will decay.

The piles may be capped with granite blocks, each of which rests on two or three piles, but not on more, owing to the difficulty of securing even bearing. The footings are started above the granite. Another method is to excavate the ground for a depth of 12 inches between the piles, to fill in between them with good cement concrete in layers, and to raise the concrete about 18 inches above the level of the pile head [14]. The concrete filling up to the level of the heads may be usefully employed under granite capping.

A third method is to connect the heads of the piles with heavy timbers, say 12 in. by 12 in., secured with bolts to the piles and running in the direction of the rows, and upon these to lay strong transverse timbers to receive the concrete [13]. In this case all such timbers must be kept below the water level. In the case of foundations which are liable to spread—such as sand with water—but which if confined will carry considerable loads, the whole area of the site may be surrounded with sheet piling and the site covered with a thick bed of concrete. When the depth of the soft ground is so great that solid ground cannot be reached, piling may still be resorted to, but in this case the piles will depend solely on the friction between the sides and the surrounding earth, and will not carry so great a load as if driven to the solid, and will generally require to be about 40 feet long. Other methods are to use very deep beds of concrete under the walls, which by their weight will compress and solidify the ground.

Underpinning. Underpinning, which consists in carrying down an existing wall to a greater depth and providing it with a new foundation without disturbing the superstructure, is often necessary. If the superstructure is heavy, it must be *shored* and perhaps *needled*, but with light structures, if the wall is thoroughly sound, this is not always necessary.

The old footings and cement must usually be cut away, the excavation to receive the new work carried down in short sections at a time, not more than three or four feet in length [see BRICKLAYER]. When the first series of excavations have been made and the work set, the intermediate pieces are dealt with. Great care is required to see that the concrete surfaces between the successive blocks are clean and a good junction is made. The brickwork is toothed all the way up.

To be continued

A SHORT DICTIONARY OF TERMS USED IN BUILDING

COMPRISING EXCAVATING, TIMBERING, SHORING, DRAIN LAYING, ETC.

AGRICULTURAL DRAIN—A drain conveying surface water from land.
Asphalte—A natural bituminous substance impervious to water.

BALLAST—Sandy gravel dredged from river beds used for concrete.
Ballast, burnt—Clay dug from excavations and burnt in its natural state.
Barrel drain—One in the form of a hollow cylinder.
Bends—Channels or pipes curved on plan.

CEMENT—A material used for binding together other material and capable of setting without the access of air.
Cement concrete, and mortar—Concrete or mortar the matrix of which consists of cement.
Centre—Temporary frame of wood on which an arch or vault is constructed.
Cesspool—A well formed below the ground to receive sewage.
Chair—Support used in drain laying to raise pipes above concrete bed.
Channel pipe—Pipe of half round section.
Clamp—Rectangular mass of crude bricks stacked for burning.
Clay puddle—Clay tempered with water.
Cleaning eye—An opening in a pipe through which it may be cleansed.
Cleat—Block of timber fixed to any timber to support a strut.
Clinker—A small vitrified brick used for paving.
Coffer dam—A temporary water-tight wall of timber and clay puddle to keep out water during building operations close by.
Concrete—A compound formed of various hard dry materials mixed with lime or cement and water which sets into a solid mass.
Crane—Machine for raising and shifting heavy weights.

DEAD SHORE—Vertical shore carrying a dead load.
Derrick—Form of crane often raised to and used at a great height from the ground.
Derrick stage—Form of gantry to support an elevated derrick.
Disconnecting chamber—Chamber formed in the length of a drain in which the house drain is disconnected from a sewer.
Dog-iron—Iron bar with ends sharpened and bent to right angles for holding together heavy timbers.
Drain—Pipe for the conveyance of sewage and waste water.
Drain-pipes—Cylindrical tubes used to form a drain.

EXCAVATION—A trench, pit, or tunnel dug out below the level of the ground.
Excavator—Labourer who digs and removes earth, etc., to level sites or form trenches, pits, and tunnels.

FENDER—Balk of timber placed outside a gantry to keep carts from damaging the uprights.
Flat centring—Temporary frame of wood on which a flat concrete floor is formed.
Flushing tank—Chamber filled with water and discharged at intervals to cleanse drains.
Flying shore—One placed horizontally across an open space between two buildings.
Fresh air inlet (abbreviation F.A.I.)—Inlet into disconnecting chamber of a drain to admit ventilation.

GANTRY—Temporary erection of squared timbers for dealing with heavy loads.
Granolithic—Species of fine concrete formed with granite chips used for paving and steps.
Gravel—Natural soil composed of small stones and sand.
Grease-trap—Form of trap to receive the discharge from a scullery sink.
Grub up—To break up and clear old foundations, drains, roots, &c., from a site.
Gully—Form of trap to receive waste water from ground surfaces or pipes.

HARD CORE—Hard dry broken rubbish.
Head—In gantries the beam carried by the uprights.
Hoggin—Screenings from pit gravel used for covering paths.
Holdfast—Iron spike with flat head for driving into brickwork.
Hoop-iron—Long flat strips of iron of various widths and gauges.
Horsing—Term used for strutting up centring from a solid base.
Hydraulicity—Capacity of cements and some limes to set without exposure to the air when mixed into a paste with water.

INSPECTION EYE—Opening in a drain or pipe by which it may be examined.
Invert—Lower part of a drain-pipe or sewer.

JUNCTION—Drain-pipe with side inlet for another pipe.
Junction block—Block built into sewer with inlet for drain-pipe.

LAGGINGS—Strips of wood nailed to centres to carry wide arches and vaults.
Lamp hole—Aperture for lowering a light into a drain.
Ledger—In scaffolding the horizontal timber carrying putlogs.
Lime—Material produced by calcining limestones.
Limekiln—Structures in which lime is calcined.
Loam—Soil in which clay prevails.

MADE GROUND—Ground which has been filled in, not virgin soil.
Main drain—Principal drain with which branch drains are connected.
Manhole—Chamber formed in the length of a drain for cleansing and to receive branch drains.
Metalling—Hard material forming the wearing surface of a road.
Monkey—Moving weight used in a pile engine for driving piles.

NEAT CEMENT—Cement used without sand.
Needle—In shoring a timber passed through a wall the ends of which are supported. Also the small timber inserted through wall-piece to receive head of raking shore.

PILES—Long timbers driven into loose ground to support superstructure.
Pile engine—Apparatus for driving in piles.
Plaster of Paris—Material produced by calcining gypsum (*selenite*).
Poling boards—Short boards used in timbering foundations.
Portland cement—Artificial cement of great strength and eminently hydraulic.
Pumice—A light volcanic stone.
Putlogs—Short square timbers used in scaffolding to carry scaffold boards.
Putlog holes—Holes left in brick walls to receive the inner end of putlogs.

QUICKLIME—Material produced by calcining pure limestone.

RAKING SHORE—One making an inclination with the horizon.
Retaining wall—One built to uphold a bank of earth.
Riding shore—One not carried down to the ground, but rising from the back of a raking shore.

SAND—Fine very hard material procured from pits, river beds, and the seashore, may also be crushed from sandstone.
Scaffold—Temporary erection from which permanent walls are constructed.
Scaffold boards—Stout boards with ends bound with hoop-iron, used to form platforms on a scaffold.
Scaffolder—Superior labourer specially engaged in erecting and altering scaffolds.
Scaffold height—Distance between successive ledgers in a scaffold, usually five feet.
Screw pile—Hollow cylindrical iron pile with large projecting screw at its base.
Selenitic lime or cement—One containing a small proportion of sulphate of lime, as plaster of Paris.
Setting—Hardening of a lime or cement mixed into a paste with water.
Sewer—Drain usually under public road to receive drainage of several buildings.
Shoring—The system of propping or strutting a building temporarily with timbers.
Silt—Muddy deposit from rivers.
Slaking—Chemical combination of quicklime with water.
Sleeper—In a gantry the horizontal beam on which the uprights stand.
Socket-pipe—One having socket formed at one end to receive end of next pipe.
Solepiece—Timber on which a system of shores rests.
Spigot end—End of a pipe that fits into socket.
Spoil—Material that has been excavated.
Standards—Vertical posts of a scaffold.
Steening—Brick lining without mortar in a cylindrical well or cesspool.

TAPER PIPE—One of which the diameter is regularly reduced from end to end.
Tar paving—Mixture of tar and shingle used to pave footpaths and areas.
Three-quarter pipe—Pipe of which three quarters of the circumference is formed.
Trap—In drainage a device to prevent the admission of sewer gas into a building while allowing sewage to pass through it.
Traveller—Small crane mounted on rails and able to move to and fro.
Trench—Excavation with parallel sides for the base of a wall or for a drain.
Turning piece—A small centre cut from a thick board on which arches with narrow soffits are constructed.

UPRIGHT—Vertical timbers of a gantry.

WALINGS—Horizontal timbers used in connection with piling and in timbering excavations.
Wall piece—In shoring, a wood plate placed vertically against the wall.
Water seal—Depth to which the upper part of a trap extends below the water standing in it.

FACTORS AND NUMBERS

The Metric System; Factors and Prime Numbers; Highest Common Factor and Least Common Multiple, with Problems

By HERBERT J. ALLPORT

THE METRIC SYSTEM

49. In most European countries the *Metre* is the unit of Length. This is the fundamental unit of the Metric System; the units of weight, area, and capacity all being derived from it.

The Metre was originally defined as being one ten-millionth of the calculated distance from the equator to the north pole, measured on the meridian of Paris. Its equivalent in English measure is approximately 39·37 inches.

The metre is divided into 10 equal parts, called *decimetres*; the decimetre into 10 equal parts, called *centimetres*; and the centimetre into 10 equal parts, called *millimetres*.

Similarly—10 metres = 1 *decametre*,
10 decametres = 1 *hectometre*,
10 hectometres = 1 *kilometre*,
10 kilometres = 1 *myriametre*.

Thus, Greek prefixes, *Deca-*, *Hecto-*, etc., indicate units greater than the metre, and Latin prefixes indicate units less than the metre.

The abbreviations for Decametre, etc., are Dm., Hm., Km., Mm.; and for decimetre, etc., are dm., cm., mm.

50. Since the system is a *decimal* system (*i.e.* based on the number 10) the *notation* will be exactly the same as that in Art. 29.

Thus, 8 Dm. 5 m. 7 dm. 4 mm. will be written 85·704 metres.

The process of Reduction consists of no more than an alteration in the position of the decimal point.

For example, 85·704 metret is equal to 857·04 dm., or 8570·4 cm., or 8·5704 Dm., or ·085704 Km., etc.

Addition, subtraction, multiplication, and division, are done just as in Arts. 30–33.

Example 1. Add together, and express in metres, 4128 cm., 5926 mm., 782 dm., 519 cm., 2900 mm.

41·28 5·926 78·2 5·19 2·9 133·496 metres *Ans.*	Express each quantity in metres, by moving the point. Write the points under one another, and proceed as in Art. 30.

Example 2. How many times can 5 dm. 2 cm. 7 mm. be subtracted from 6 m. 3 dm. 2 cm. 4 mm.?

Here, required no. =

$$\frac{6\text{ m. }3\text{ dm. }2\text{ cm. }4\text{ mm.}}{5\text{ dm. }2\text{ cm. }7\text{ mm.}} = \frac{6324\text{ mm.}}{527\text{ mm.}} = 12\text{ times } \textit{Ans.}$$

51. The unit of Surface is the Square Metre. The table is—

100 sq. mm. = 1 sq. cm.
100 sq. cm = 1 sq. dm.
100 sq. dm. = 1 sq. m.
100 sq. m. = 1 sq. Dm.
etc.

The Are = 100 sq. metres. Its multiples are the decare, hectare, etc., and its divisions the deciare, centiare, etc.

The unit of Volume is the Cubic Metre.
The table is—

1000 cu. mm. = 1 cu. cm.
1000 cu. cm. = 1 cu. dm.
1000 cu. dm. = 1 cu. m.
etc.

The unit of Capacity is the Litre, and is equal to the content of a cubic decimetre. (English equivalent = $1\frac{3}{4}$ pints, approx.) Hence, we have centilitre, decilitre, etc.

The unit of Weight is the Gramme, or Gram, and is equal to the weight of 1 cubic cm. of distilled water at a temperature of 4° Centigrade Hence, kilogramme, hectogramme, etc.

1 quintal = 100 kilogrammes.

52. The French system of Money is also connected with the metre: the *franc* being a silver coin weighing 5 grammes. 1 franc = 100 centimes.

EXAMPLES 8

1. Write in litres and add together, 179486 dl., 2951 Dl., 307 l., 54 Hl., 729825 ml.
2. Write in sq. metres, and add together, 12345 sq. cm., 43 sq. Dm., 3529 sq. m., 7146 sq. dm.
3. Writes in ares, and add together, 42 sq. decametres, 6240 sq. metres, 275 deciares, 42 hectares.
4. Multiply 24 grams, 5 dg. 4 mg. by 63. Give the answer in cgs.
5. How many times can 47 mm. be taken from 90 Hm. 7 Dm. 2 m. 3 dm. 5 cm.? Express the remainder in metres.
6. Find the value in francs of 124 Kg. 3 Hg. 5 g. of salt, at 25 centimes per Kg.
7. What will be the cost of 2 Hl. 7 Dl. 5 l. of wine, at 3 francs 50 centimes per litre?
8. How many sheets of cardboard 1·5 mm. thick are there in a pile 2·7 metres high?
9. Assuming 8 kilometres = 5 miles, how many minutes shall I take to walk 1 kilometre, if I walk at the rate of 4 miles per hour?

FACTORS

53. We have seen (Art. 15) that when two or more numbers are multiplied together, the result is called the *product* of the numbers, and each of the numbers is called a *factor* of the product.

A *prime number* is a number which has no factors (except itself and unity).

Any other number is called a *composite* number. The *prime factors* of a composite number are the prime numbers whose product is the composite number.

Example. *The prime factors of 60 are 2, 2, 3, 5. For 2, 2, 3, 5 are all prime numbers, and their product is 60.*

Two numbers are said to be *prime to one another* when there is no number except unity which will divide both of them exactly.

Example. 18 and 35 are prime to one another, since no number will divide both 18 and 35 and leave no remainder in either case.

Note, however, that neither 18 nor 35 is a prime number.

54. The prime numbers less than any chosen number, say 100, can be found in the following way. Write down all the numbers from 1 to 100. Then, starting from 2, strike out every second number (*viz.* 4, 6, 8, etc.). This, of course, removes all multiples of 2. Next, go to the first number above 2 which is not struck out, *i.e.* 3, and, starting from here, strike out every third number (*viz.* 6, 9, 12, etc.). Now take the next number above 3 which is not struck out, *i.e.* 5, and starting from 5, strike out every fifth number (*viz.* 10, 15, 20, etc.)—and so on.

NOTE. In the example just considered it will not be necessary to continue the process after we have started from 11. For on dividing 100 by 11, the quotient is less than 13, the next higher prime. Hence, if any of the numbers are divisible by 13, the quotient must be less than 11, *i.e.* they are multiples of numbers less than 11, and therefore have already been struck out.

55. The prime numbers less than 100 are thus found to be 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89 and 97.

Example 1. Is 691 prime or composite?

It is only necessary to find, by trial, whether 691 is exactly divisible by any *prime* number less than 691. For, if it were divisible by any *composite* number, it would plainly be divisible by the prime factors of that number.

By trial, we find there is a remainder in each case when 691 is divided by 2, 3, 5, 7, 11, 13, 17, 19, 23, 29. We need not try any higher number than 29, because the quotient in that case is less than 31, the next prime. [See Note above.]

Example 2. Find the prime factors of 315084.

$$\begin{array}{r|r} 2 & 315084 \\ \hline 2 & 157542 \\ \hline 3 & 78771 \\ \hline 7 & 26257 \\ \hline 11 & 3751 \\ \hline 11 & 341 \\ \hline & 31 \end{array}$$

Here, by trial, we find that 315084 is divisible by 2; the quotient obtained is divisible by 2; the second quotient is divisible by 3; and so on until we obtain a prime number, 31, for quotient.

$\therefore$ 315084 = $2 \times 2 \times 3 \times 7 \times 11 \times 11 \times 31$ *Ans.*

56. In finding the factors, whether prime or composite, of a given number, it is often possible to test its divisibility by another number, without performing the operation of division. The following are some of the most useful cases:

1. Every number is a multiple of 10 + *its units digit.* $\therefore$ a number is divisible by 2 if its units digit is divisible by 2.

Such a number is called an *even* number. A number which is not divisible by 2 is called an *odd* number.

2. Every number is a multiple of 100 + the number formed by its two right-hand digits. But every multiple of 100 is divisible by 4. Hence, if the number formed by the last two digits is divisible by 4, so is the number itself.

NOTE. Since $100 = 4 \times 25$, the same test will show whether a number is divisible by 25.

3. In a similar manner we may show that a number is divisible by 8 (or by 125) if the number formed by the last *three* digits is divisible by 8 (or by 125).

4. For the same reason as in [1], a number is divisible by 5 if its units digit is divisible by 5, *i.e.* if its units digit is 0 or 5.

5. A number is divisible by 3 if the sum of its digits is divisible by 3.

For, consider the number 6237.

We know that

$$\left.\begin{array}{r} 1000 = 999 + 1 \\ 100 = 99 + 1 \\ 10 = 9 + 1 \end{array}\right\} = \text{a multiple of } 3 + 1, \text{ in each case.}$$

Therefore

$$\left.\begin{array}{r} 6000 = \text{a multiple of } 3 + 6 \\ 200 = \text{a multiple of } 3 + 2 \\ 30 = \text{a multiple of } 3 + 3 \end{array}\right\}$$

Hence, by addition,

6237 = a multiple of $3 + 6 + 2 + 3 + 7$, so that, evidently, 6237 is divisible by 3 if $6 + 2 + 3 + 7$ is divisible by 3, *i.e.* if 18 is divisible by 3.

6. In the same way we can show that a number is divisible by 9 if the sum of its digits is divisible by 9.

7. A number is divisible by 11 if the difference between the sum of its first, third, fifth, etc. digits and the sum of its second, fourth, sixth, etc. digits is divisible by 11.

Consider the number 38632.

We know that

$$\left.\begin{array}{rr} 10000 - 1, \textit{i.e.} & 9999 \\ 1000 + 1, \textit{i.e.} & 990 + 11 \\ 100 - 1, \textit{i.e.} & 99 \\ 10 + 1, \textit{i.e.} & 11 \end{array}\right\} \text{are multiples of 11;}$$

Therefore

$$\left.\begin{array}{r} 30000 - 3 \\ 8000 + 8 \\ 600 - 6 \\ 30 + 3 \end{array}\right\} \text{are multiples of 11.}$$

Hence, by addition,

$38632 - 3 + 8 - 6 + 3 - 2$ is a multiple of 11.

It follows, then, that 38632 divided by 11 must leave the same remainder as $(3+6+2)-(8+3)$ divided by 11. Consequently, if $(3+6+2)-(8+3)$, or the difference between the sum of the digits in the odd places, and the sum of the digits in the even places, is divisible by 11, so is the number itself.

HIGHEST COMMON FACTOR

57. A factor which divides each of two or more numbers is called a *common factor* of the numbers. The *greatest* factor which divides each of the numbers is called their *Highest Common Factor*, or their H.C.F.

NOTE. Any number which exactly divides another number is called a *measure* of that number. Hence the H.C.F. of two or more numbers is often spoken of as their Greatest Common Measure, or G.C.M.

58. The H.C.F. of numbers which have been expressed in *prime* factors can be found by inspection.

Example 1. Find the H.C.F. of 42, 70, and 182.

$$\left.\begin{aligned} 42 &= 2\times 3\times 7 \\ 70 &= 2\times 5\times 7 \\ 182 &= 2\times 7\times 13 \end{aligned}\right\} \text{We see that 2 and 7 are common factors.}$$

$$\therefore \text{ H.C.F.} = 2\times 7 = \underline{14\ \textit{Ans.}}$$

Example 2. Find the H.C.F. of 836, 2728, and 10010.

We need not find the prime factors of more than one of the numbers.

$$836 = 2\times 2\times 11\times 19.$$

It is clear that it is only necessary to find which of these factors are common to all three of the numbers. By inspection, 2 is common to all: but 2×2 is *not* common. Again, 11 is common to all: and by trial we find 19 divides neither of the other numbers. Hence, the common factors are 2 and 11.

$$\therefore \text{ the H.C.F.} = 2\times 11 = \underline{22\ \textit{Ans.}}$$

59. When the numbers cannot easily be put into factors, we use another method.

We must first prove that

The common factors of a divisor and a dividend are the same as the common factors of the divisor and the remainder.

Consider the numbers 121 and 341.

If we divide 341 by 121 we get 2 quotient and 99 remainder.

$$\therefore \quad 341 = 2\times 121 + 99 \qquad \text{(Art. 23)},$$
$$\text{or } 341 - 2\times 121 = 99.$$

Now, any common factor of 341 and 121 is also a common factor of 341 and 2×121, and is therefore a factor of $341-2\times 121$, *i.e.* of 99. Or, any common factor of the divisor and dividend is also a factor of the remainder.

Again, any common factor of 121 and 99 is a factor of $2\times 121+99$, *i.e.* of 341. Or, any common factor of the divisor and remainder is also a factor of the dividend.

Hence, the common factors of the divisor and dividend are the same as those of the divisor and remainder.

60. We shall apply this result to find the H.C.F. of 731 and 817.

```
731 ) 817 ( 1
       86 ) 731 ( 8
             43 ) 86 ( 2

   H.C.F. = 43 Ans.
```

EXPLANATION. Divide 731 into 817. The remainder is 86. We have shown that the common factors of 731 and 817 are the same as those of 731 and 86. We now apply the same principle to 731 and 86. On dividing 731 by 86 we get a remainder 43, and we know that the common factors of 86 and 43 are the same as those of 86 and 731, and therefore the same as those of the original numbers. We now divide 86 by 43 and get no remainder, *i.e.* 43 is the highest common factor of 43 and 86, and therefore the highest common factor of the original numbers.

61. If at any stage of the work we see a prime factor of the divisor which is not a factor of the dividend, we may take that factor out, since it is not *common*. Thus, in the above example, 2 is a factor of 86, but not of 731. We therefore take the factor 2 out of 86, leaving 43, and then divide 43 into 731. This is found to leave no remainder, so that the work finishes at this stage.

Again, if at any stage we see a factor which is common to divisor and dividend, it shortens the labour if we take that factor out; but we must remember to include the factor in the H.C.F.

Example. Find the H.C.F. of 6171 and 129129.

We see (Art. 56) that 3 is a factor of both numbers. We therefore divide each by 3, obtaining the quotients 2057 and 43043. Now, 43 is evidently a factor of 43043, and by trial we find it is not a factor of 2057. Hence, we proceed with the H.C.F. of 2057 and 1001.

```
1001 ) 2057 ( 2
        55 ) 1001 ( 18
              451
               11 ) 55 ( 5
```

This we find to be 11. Therefore the H.C.F. of the two given numbers is 11×3, *i.e.* 33.

62. To find the H.C.F. of more than two numbers, we first find the H.C.F. of two, then the H.C.F. of this result and the third number, and so on until we have used all the numbers.

LEAST COMMON MULTIPLE

63. A *multiple* of a given number is a number which is exactly divisible by the given number. A *common* multiple of two or more given numbers is a number which is divisible by each of them. The *Least Common Multiple* or L.C.M. of the numbers is the least number which is divisible by each of them.

64. If the given numbers can be put into prime factors their L.C.M. is readily obtained.

Example. Find the L.C.M. of 30, 63, and 140.

$$\left.\begin{aligned} 30 &= 2\times 3\times 5 \\ 63 &= 3\times 3\times 7 \\ 140 &= 2\times 2\times 5\times 7 \end{aligned}\right\} \begin{aligned} &\therefore \text{ L.C.M.} \\ &= 2\times 3\times 5\times 3\times 7\times 2 \\ &= \underline{1260\ \textit{Ans.}} \end{aligned}$$

EXPLANATION. The L.C.M. must be divisible by 30, therefore it must contain the factors

2, 3, 5. Next, the L.C.M. must be divisible by 63, therefore it must contain the factors 3, 3, 7. But we have already one 3 in the L.C.M., so that we have only to write 3, 7 along with the 2, 3, 5. *Similarly, since the L.C.M. is to be divisible by 140, we see that it must also have another factor 2, 2. Thus the L.C.M. consists of the factors 2, 2, 3, 3, 5, 7.*

65. The above process is usually shortened in the following way.

Example. Find the L.C.M. of 13, 15, 182, 14, 52, and 65.

$$\begin{array}{r|l} 2 & \cancel{13},\ 15,\ 182,\ \cancel{14},\ 52,\ 65 \\ \hline 5 & 15,\ 91,\ 26,\ 65 \\ \hline 13 & 3,\ 91,\ 26,\ \cancel{13} \\ \hline & 3,\ 7,\ 2 \end{array}$$

$\therefore$ L.C.M. $= 2 \times 5 \times 13 \times 3 \times 7 \times 2$
$= \underline{5460\ Ans.}$

EXPLANATION. 13 is a divisor of 65, and therefore any multiple of 65 will also contain 13. Hence we may leave out the 13. Similarly we leave out 14, since it is contained in 182. Next divide by a *prime* number which is a factor of two or more of the given numbers. In this case we see that 2 is a factor of 182 and 26. Divide those numbers by 2, and set the other numbers down with the quotients; thus, 15, 91, 26, 65. We now see that 5 is a factor of two of these numbers. Divide them by 5, and we get 3, 91, 26, 13 for the third line. We now leave out 13 since it is contained in 26. Finally, we divide by 13, which is a factor of 91 and 26. There are now only prime numbers left; and the L.C.M. is the product of the numbers in the last line and of the numbers by which we have divided.

66. If the prime factors of the numbers are not easily seen, we proceed thus. Find the H.C.F. of two of the given numbers, and divide them by their H.C.F. The two quotients can have no *common* factor. Hence (Art. 64), the L.C.M. of these two quantities is

H.C.F. $\times$ 1st quotient $\times$ 2nd quotient.

In exactly the same way we now find the L.C.M. of this first L.C.M., and the third of the given quantities. Evidently this is the L.C.M. of the three quantities. And so on, until we have used all the quantities.

Example. Find the L.C.M. of 16046, 21922, and 23843. By the rule of Art. 60 we find the H.C.F. of 16046 and 21922 is 226. On dividing these two numbers by 226, the quotients are 71 and 97. Therefore, the L.C.M. of 16046 and 21922 is

$226 \times 71 \times 97$, *i.e.* $2 \times 113 \times 71 \times 97$.

By trial, we find the only one of these factors which divides 23843 is 113. Therefore the H.C.F. of the L.C.M. already found and of 23843 is 113. Divide the L.C.M. by 113, obtaining $2 \times 71 \times 97$; divide 23843 by 113, obtaining 211.

Hence the L.C.M. of the three given numbers is

$113 \times 2 \times 71 \times 97 \times 211$.

67. To find the H.C.F. or the L.C.M. of compound quantities we must first, by reduction, *express them as simple quantities* in terms of the same unit.

Example. Find the H.C.F. and L.C.M. of 7 qrs. 14 lbs.; 3 cwts. 1 qr. 26 lbs.; 4 cwt. 14 lbs.

Reduce each quantity to lbs. as in Art. 38. Then,

$$\begin{aligned} 7 \text{ qrs. } 14 \text{ lbs.} &= 210 \text{ lbs.} = 2 \times 3 \times 5 \times 7 \\ 3 \text{ cwt. } 1 \text{ qr. } 26 \text{ lbs.} &= 390 \text{ lbs.} = 2 \times 3 \times 5 \times 13 \\ 4 \text{ cwt. } 14 \text{ lbs.} &= 462 \text{ lbs.} = 2 \times 3 \times 7 \times 11 \end{aligned}$$

Hence, H.C.F. $= 2 \times 3 = \underline{6 \text{ lbs. } Ans.}$

L.C.M. $= 2 \times 3 \times 5 \times 7 \times 11 \times 13$
$= 30030$ lbs.
$= \underline{13 \text{ tons } 8 \text{ cwt. } 14 \text{ lbs. } Ans.}$

68. We add some miscellaneous examples.

Example 1. Find the least number which, when divided by 15, 21, 35, or 45, always leaves remainder 12.

$$\begin{array}{r|l} 3 & 15,\ 21,\ 35,\ 45 \\ \hline 5 & \cancel{5},\ \cancel{7},\ 35,\ 15 \\ \hline & 7,\ 3 \end{array}$$

L.C.M. $= 3 \times 5 \times 7 \times 3 = 315$

$\therefore$ Required no. $= 315 + 12$
$= \underline{327\ Ans.}$

EXPLANATION. The least number which, when divided by 15, 21, 35, or 45, leaves *no* remainder, is their L.C.M., which is 315. $\therefore$ the smallest number which leaves remainder 12 is $315 + 12$.

Example 2. Find the greatest number which, when divided into 9505 and 20840, leaves remainders 49 and 155 respectively.

If the number divides 9505 and leaves a remainder 49, it must divide $9505 - 49$, *i.e.* 9456, and leave no remainder.

Similarly, it must divide $20840 - 155$, *i.e.* 20685, and leave no remainder.

9456) 20685 (2
1773) 9456 (5
591) 1773 (3

Required number $= \underline{591\ Ans.}$

Therefore, the number required is the H.C.F. of 9456 and 20685.

Example 3. A man walking along a road notices a mile-stone standing against a telegraph pole. He finds the telegraph poles are 66 yards apart. How far will he walk before he again finds a mile-stone against a telegraph pole?

He will evidently have to walk a distance which contains 66 yards an exact number of times, and which also contains 1 mile an exact number of times. The *least* distance he must walk, then, will be the L.C.M. of 66 yds. and 1 mile, *i.e.* of 66 yds. and 1760 yds. This is found to be 5280 yds., or $\underline{3 \text{ miles } Ans.}$

DRAWING & THE HUMAN FORM

Choice of Work. How to "Block in." The Power of Line. Aids to the Artist's Career. Drawing from Life. The Human Form

By P. G. KONODY

The Artist's Choice of a Career. The student on the threshold of an artistic career should be very decided as to what branch of art he intends to master. If all his joy be in colour, he should give his strength to so mastering colour that it shall express the mood of the thing he wishes to create; and he should at the same time remember that there are other ways of painting, often vastly more lucrative, than the mere making of easel pictures. He should look to the career which will give him the greatest scope for his powers and the largest outlet for employment—such as the decoration of the walls of houses. Then, again, the illustrating of books and papers created some of the noblest art of the last fifty years. This field is to-day seriously damaged by the widespread use of photography; but photography can never compete with the creative artist in invention, and for the man of ideas there is still scope even in illustration, though the field is very limited. There is, on the other hand, wide scope for the employment of his art in advertisement such as the designing of the picture poster.

If, however, his joy be form, and he decide to be a sculptor, the same advice applies to him, for whilst his chances in selling the imaginative piece must always be limited, there is wide scope for him in the modelling of beautiful articles for everyday use and in creating decorative sculpture for buildings. In short, let nothing be too large or too small for the exercise of the artist's gifts—the more he does, the more facile will become his hand's skill in creation. There was never such a crying need for the beautifying of life by making every utensil and adornment in the home and in the street a joy to the eye.

What He Must Teach Himself. Having decided, then, on the province of art which he will make his own, the student is at once brought face to face with the serious question of training and pupilage. It is evident that the student will have to go through a certain amount of schooling in order to learn modelling in clay if he desire to become a sculptor, or the handling of paint if he wish to become a painter; but it is astounding how much he can learn even of these things in a short time, if he will first of all teach himself what he can alone learn by his own application and taste—to draw. Some men have risen to fame without more schooling in the arts than they could get from their own industry and the fellowship of other students. But whether a man be blessed with the inestimable advantages of seeing the great masters at work, or, better still, of working in their studios as pupil; or whether he may have to discover the craftsmanship of his art step by step for himself, there is one thing above all others that he *must* teach himself, and that is to draw with ease anything that may come his way, so that drawing becomes a habit. Drawing is to the artist what words are to him who would speak well; and just as a thorough grasp of English enables a man to speak it without any conscious effort, so a thorough mastery of detail should enable the artist to draw with such facility that his mind is not harassed by any of the countless difficulties which bewilder the student at the beginning.

The Habit of Drawing. This habit of drawing, which is at the base of everything that an artist does, which is in fact beneath every brushful of paint before that paint can be placed exactly where he wishes to place it, which is beneath the stroke of the chisel before the chisel can be made to yield form—this habit of drawing is the base and foundation of everything the artist does or may ever hope to do. And this art of drawing he *must teach himself*, whether he go to an art-school or become the pupil of a master, and by his own powers and gifts alone can he acquire it. He cannot begin too soon, for he must go through an ugly, hard, rigid stage of striving before the secret comes to him—nothing is too humble for him to draw. One day mastery may burst upon him almost as by magic, and he will find his hand drawing any form he desires to express, just as, in learning to read, his eye takes in the word without spelling it.

It is clear, therefore, that it is a waste of time to enter a class of painting before the hand can obey the will in its desire to express the form of things; let us therefore proceed to show the way along the road to art by showing what the student must teach himself; and when he is fit to take advantage of the schools we will lead him thither and through.

Drawing from Memory. Besides drawing direct from nature the student should practise from the outset memory drawing. He should try to record with his pencil what his eye has observed in street or field. And if he fail, let him go out and look again, and then correct his drawing until he is satisfied with the result. He will find this especially useful for the expression of movement, and his eye will soon acquire the custom of retaining each successive stage of rapid motion. This is the method of training followed by the Japanese, and in it lies the secret of the charm of Japanese art, which expresses with bold simplification the salient points which the eye can take in at a quick glance, omitting the detail which can only be observed in complete repose.

How to "Block in." The student's first step, then, is to use drawing as a habit. Now, the tendency of the beginner, when he starts to draw an object, is to begin with details, which is disastrous. He should first of all "block" in the mass, as it is called, then "block" in the mass of the detail, and then get the *accurate* forms. For instance, in sketching the human figure, first roughly sketch the main proportions so as to get the swing and action and general relations of the parts one to the other, so as to get the proportions right; then roughly sketch the general form of the details of the head and limbs; then with telling lines get the true form of the features and the wondrously beautiful lines of the limbs, so that when even the outlines of the figure are drawn, they seem to hold the forms and state their character and suggest flesh.

It is a good thing—indeed it is the best master in the wide world—to collect prints and cut out of old magazines good drawings by well-known artists, and to copy them—not only the work of one man, but the work of many, so as to learn to say with line what they could say. The choice of the masters will depend upon the taste of the student; but the chalk portrait heads of Holbein, the many sketches in chalk by Lord Leighton, and the clear, firm drawings of such popular draughtsmen as Phil May, Randolph Caldecott, and the like, are invaluable guides to drawing; whilst Sir Edward Poynter issued a series of drawing-books for students of the antique which are good training in chaste, clear line of the beauty of form to be learnt from the great Greek sculptors. It is capital practice, too, to get photographs of well-known people and of beautiful women, and to sketch them in line, always remembering to "block in" the whole head first, then to draw the details in their true relation to each other afterwards. Indeed, the very collecting of

"THE SOWER," BY J. F. MILLET

"THE GLEANERS," BY J. F. MILLET

Both these pictures illustrate the power of line: "The Sower," by its noble swing, suggests the mastery of man over Earth. "The Gleaners," by its curves, suggests Earth enslaving man

good examples of drawing will train the eye far better than all the directions that could possibly be given.

Detail. The rough lines to "block out" the object are, needless to say, only to give a rough idea of where the real form will come; but when the details are drawn, then every line should be so true that the very object seems to be enclosed within them. In the first rough sketch of the general form and swing of the figure, for instance, we are only seeking to get proportion, and the general idea of the ground to be covered. But the drawing of the detail that will then be set within this rough sketch cannot be too true or too beautiful in its effect upon the eye.

Exactly the same advice applies to a landscape. Rough sketch the relation of things as a whole, roughly showing where the masses of dark and light will come, and the general lines. Then sketch in the details, which will not now get out of place.

It used to be the habit in the art schools to set a pupil to draw a Greek statue, and laboriously spend weeks and months in stippling and cross-hatching the light and shade of every detail of it; but this is a pitiful waste of power which should be applied to the acquiring of ease, deftness and swiftness in setting down the form of things. And even if a student be attending an art school, all his work there will be empty of result if he is not constantly drawing as swiftly and well as he possibly can every object that he sees about him. Then, when the day comes that he awakes to find drawing a habit, he will not only be able to paint without being harassed with the difficulty of drawing, but he will be able to concentrate all his powers upon getting the colour true. Many a boy has come to hate literature because he was compelled to learn Shakespeare before he could understand him; in the same way art is choked out of many a lad by the boring and tedious effort to draw objects like old statuary until he hates every detail of the beautiful object.

Everything holds a character of its own, and that character can be given by drawing. It used, for instance, to be a stupid axiom amongst artists that trousers were without any character but that of stove-pipes; but men like Phil May came and proved that the lines and forms of trousers contained an astounding amount of character, whether they were the ragged wear of beggars, the dandified grotesqueness of costermongers, or the inherited breeches of street-boys. Boots hold a rare amount of the character of the feet they cover, character which they betray to the man with eyes sufficiently inquisitive to seek them out and draw them.

Line. Now as regards the line. The student should draw with the line as the musician uses a note of music on a violin—making the line swing out or thin down as it suits the form he would draw. It is an education to look at one of Holbein's chalk portraits to see how the line caresses the form of the brow, and seems to disappear over the curved edge, to start again and sweep over the cheek bone. The line as it forms the nose seems to search out every subtle curve and form, until it disappears into the flesh under the nostril. Then, again, take a pen drawing by Aubrey Beardsley—see how musical is the sense it gives. When the line with its simple curve sweeps round the edge of the head, neck and shoulders of some beautiful woman, it seems to be made of delicate flesh—it suddenly breaks into a series of dots that seem to be made of very muslin, tracing the delicate folds of gossamer draperies—then the line takes a stronger note and sweeps out the form of the silken gown, rippling along to make the flounces, and criss-crossing net-wise to state the netlike quality of some transparent veil. There is scarcely any master who could do more with the sheer beauty of his line than Beardsley, whose work is easily within the reach of any student. There are lessons innumerable in Randolph Caldecott's nursery books, not only of how line

JOHN FISHER, BISHOP OF ROCHESTER, BY HOLBEIN
To illustrate the freedom and power of the master's line
[From the original in Windsor Castle]

properly and fitly handled can *speak* to the eye, but also in the great beauty of colouring achieved by simple broad washes of water-colour—an excellent practice which greatly enhances the value of a pencil drawing, or of a drawing done with indelible black ink, which may be bought from any artists' colourman.

Modelling. At the same time that the student is mastering pure line, he should not only use the pencil and the pen, but he ought from the very first to draw with the brush as well, getting his hand used to the loose point and the tricks of the tool. He should try to get a copy of the "Studio's" special number upon "Modern Pen Drawing," and Joseph Pennell's most useful volume on pen drawing, with its invaluable examples by various artists, a book which is an education in itself, since it shows what wondrous beauty can be produced by sheer line.

It would be better still for the student to collect a book of his favourite drawings and so develop his own taste. And there are innumerable superb examples of the work of Edwin Abbey, Howard Pyle, Dana Gibson, and others in the American magazines, which are better than much schooling. At foreign booksellers may be procured for a few pence the work of Frenchmen like Steinlen, and of Germans and other foreign artists in papers like *Jugend* and *Simplicissimus*, which are not only a joy to possess, but which are also a rare education in drawing. Also, from the beginning, whilst the student is still giving all his strength to the mastery of drawing, he should try to sweep in broadly the modelling of the masses; not going into the details as in the old academic methods, but still getting the larger values. Thus, when he acquires correctness in drawing, he will be able to model in the detail with ease.

A very useful thing, until the student can afford the schools, is to get photographs of horses, dogs, animals, or people, whether in magazines or otherwise, and try to draw them in freehand.

The Human Form. We now come to drawing from the human form. A certain amount of anatomy may be learnt from books on this subject, but the best way to learn it is to take the male figure and the female, and to *draw* them into your knowledge. Mere reading of books on anatomy is sheer waste of time. The chief muscles and the bones should be *drawn*, so as to give the hand the knowledge as well as the head. The student will find that when he draws a head, he is inclined, as he goes on drawing the figure, to elongate each part more and more out of all proportion to the head. Some students are inclined to do the opposite and shorten the proportions—a very ugly fault.

It is best in drawing from life, to tick off the proportions so as not to let the pencil stray, as it is inclined to do, into elongation. The figure roughly divides into two at the top of the legs, and artists make the head the standard of measurement, always speaking of the figure or parts of the figure as so many "heads." The height of the head goes into the upright figure seven and a half times (the Greeks made it eight, as we shall see). The first head is, of course, to the chin, the second *head comes to the nipples of the breasts, the third head to the navel, and the fourth head to the top of the legs. This is half the figure, or the whole of the head* and trunk.

The fifth head comes down the thigh so far as to allow the knee to come midway between it and the next head, the sixth; while the seventh head reaches to the ankle. The foot, then, is midway in the eighth head, as the knee was midway in the sixth.

A Permissible Exaggeration. The Greeks made the shin longer, so that the foot came to the eighth head, and the figure acquired an added grace and dignity due to the length from the knee to the heel. It is a very permissible exaggeration, often employed with fine effect by men like Leighton.

The length of the figure kept within check, the student is not liable to go very far wrong with its breadth; but it is well to have a rough rule of thumb for the face

BOY: "No? Why, don't you *never* treat yourself to no luxuries, guvner?"

THE EXPRESSIVENESS OF LINE: A PEN-AND-INK DRAWING BY PHIL MAY.

HERMES, BY PRAXITELES

THE VENUS OF MILO

THE GREEK IDEAL OF BEAUTY

and head also. The face is halved across the eyes; the nostrils form the quarter line (or half the lower half). The hair, roughly speaking, forms the upper quarter (or half of the upper half). The ears should in the full face therefore come between the cross line of the eyes and the cross line of the nostrils. The width of the face is roughly twice the length of the nose, or twice the length from the nose to the chin.

It is well constantly to draw the male and female figure from memory—back, front, and side view—until the proportions are so set in the memory as to become fixed; in fact, the student should be able to draw them almost with his eyes shut. It is astonishing how accurate the brain becomes in holding these facts when drilled to it—just as it holds pages of verse by training, stored away until called for. These six forms, three of the male and three of the female figure, are enormously valuable to the artist's memory and hand.

HOW A FLOWER IS BORN

Maintenance of the Life of the Species. Germination and Development of Seeds. Structure and Parts of Flowers and Plants. Classification

By Professor J. R. AINSWORTH DAVIS

HOWEVER successful an individual plant or animal may be in the struggle for existence, the species to which it belongs would of course die out were there not some provision for the production of new individuals. And we find that in all organisms parts of the body become detached and ultimately grow into the members of a new generation. This process is *reproduction*, or *propagation*, and may be effected by seed-plants in a variety of ways.

Kinds of Reproduction. A broad distinction is drawn between *vegetative reproduction*, in which some of the parts helping in the maintenance of the life of the individual become detached, and *sexual reproduction*, which is of more specialised nature, and is ministered to by the flower.

Good examples of the former are afforded by the potato and strawberry. What is familiarly known as a "potato" is really a thickened branch of an underground stem, crammed with starch and other kinds of nutritive matter and technically called a *tuber* [40]. If allowed to remain in the ground the *eyes*—which are really buds—will grow into shoots that rise above the surface, while roots grow out from their lower nodes. The result is a new plant. As everyone knows, this valuable article of food is usually propagated by means of the tubers, which are cut into pieces, care being taken that each of these possesses at least one eye or bud.

In the case of the strawberry, long thin branches, the *runners*, grow along the ground away from the parent plant. From every node roots and a shoot can be produced, which grow downwards and upwards respectively [41]. By decay of the internodes the connection with the parent is lost, and a number of young distinct plants are the net result.

The Flower. Some of the branches of the stem in our pattern plant, instead of giving rise to nothing but ordinary foliage-leaves, bear one or more flowers, into the nature and use of which we must now inquire. We will suppose these to be "pattern flowers," answering to the general plan of which all flowers are variations, just as we may look upon the many kinds of clock and watch as being modifications of a pattern or diagrammatic time-piece, such as a teacher of clock-making might devise to illustrate the essential parts common to all pieces of mechanism—apart from such things as sun-dials—of which the use is to tell the hour of the day or night.

The flower is in reality a greatly specialised shoot, concerned with the production of healthy seeds, capable of growing into fresh plants. Like all shoots, it is a stem bearing leaves, though these differ more or less from ordinary foliage-leaves, in accordance with their different use. It is borne on a *flower-stalk*, which may also bear simplified and often scale-like leaves known as *bracts*.

Parts of the Flower. Consider the parts of the flower [42]. The central stem-part, the *receptacle*, is very short, owing to the suppression of its internodes, so that the different flower-leaves which it bears are crowded together, much in the same way as are the foliage-leaves in the rosettes of the dandelion and daisy, to which allusion has elsewhere been made. The flower-leaves are of four kinds, arranged in two sets, (a) the *perianth* or *covering-leaves* externally, and (b) the *essential* or *reproductive leaves* internally.

The two sets of leaves of which the perianth is composed are an external circlet or *whorl* of five *sepals*—collectively termed the *calyx*—and an internal whorl of five *petals*, alternating with the sepals and together making up the *corolla*.

The *Sepals* are firm and green, being more like foliage-leaves than their associates. They protect the delicate internal parts of the flower, especially in the bud.

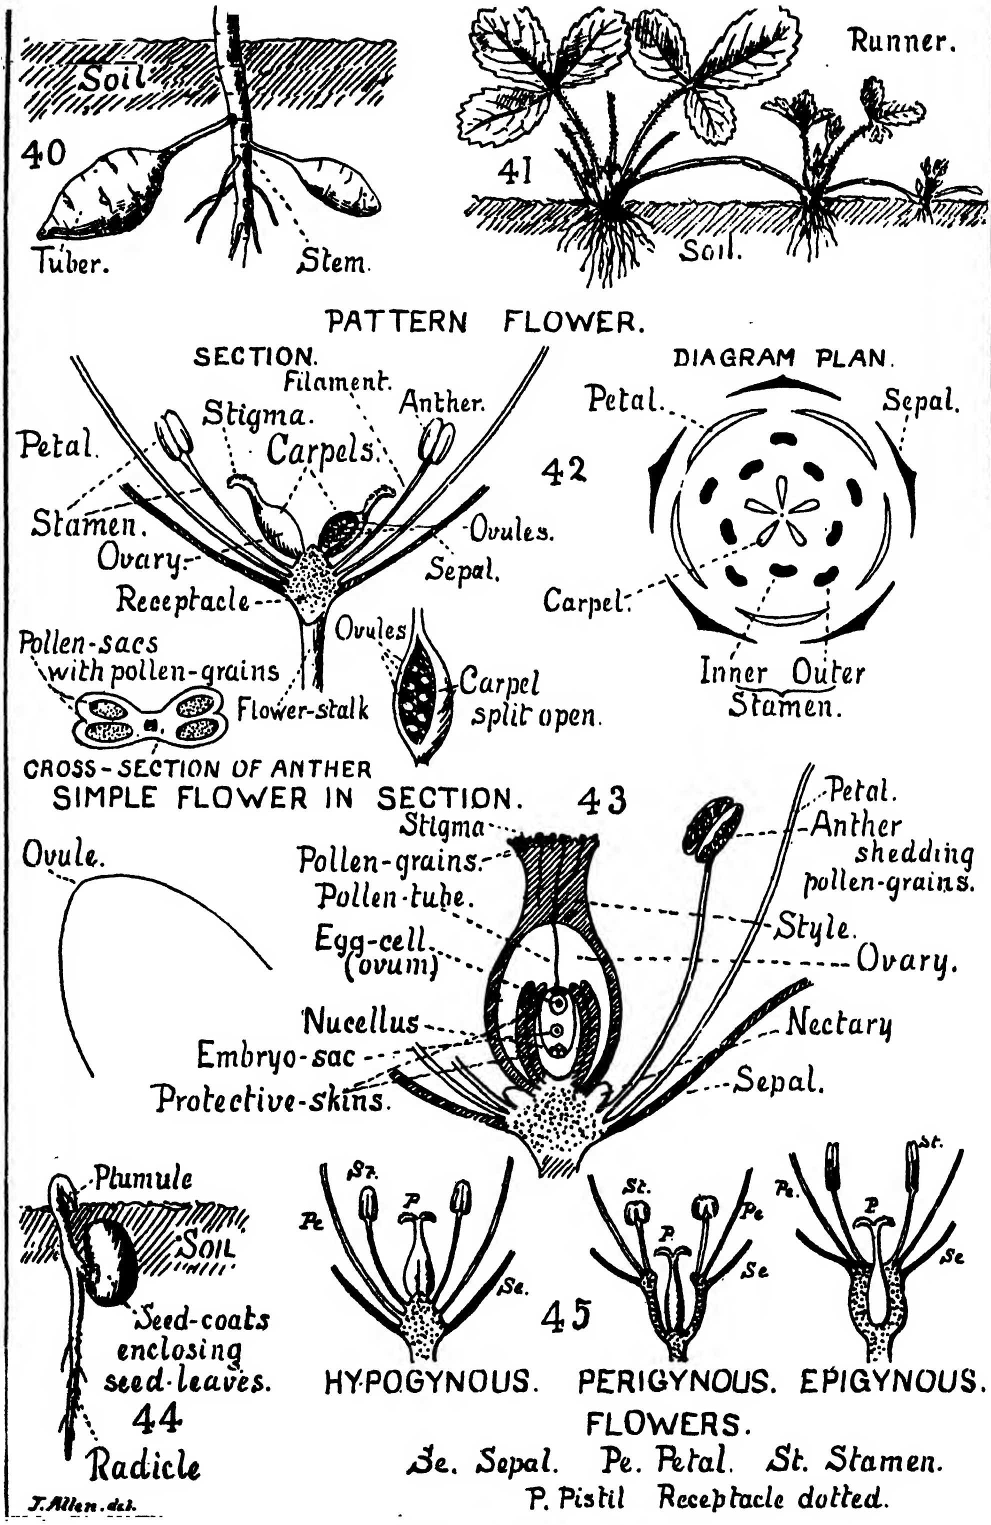
The *Petals* are larger and more delicate than the sepals, and are brightly coloured. They help to protect the essential leaves, but their chief use is to make the flower conspicuous, in order to attract insects. The object of this will presently become apparent.

Reproductive Leaves. In the essential or reproductive leaves, again, we have two sets of structures—*i.e.* two whorls of *Stamens*, five in each whorl, and a whorl of five *Carpels*. The members of each whorl alternate with those of the preceding one.

The *Stamens*, which are to be regarded as the male part of the flower, differ greatly in appearance from the petals and sepals. Each of them is like a thread with a thickened end, the two regions being the *filament* and *anther* respectively. In the latter is produced the *flower-dust*, or *pollen*, which probably everybody has noticed in a lily or tulip. If a young anther is cut across and examined under the microscope it will be found to contain four pollen sacs in which the particles of this yellow dust, the *pollen-grains*, are formed. They are essential to the formation of the seed, as we shall presently see, and are liberated by the splitting of the anthers.

Except that the *Carpels* are green, they differ widely in appearance from leaves, but each of them is really a folded leaf, of which the two edges have coalesced. Sheltered within the cavity are a number of minute green bodies, which grow out from the edges of this folded leaf,

TYPES OF FLOWERS



PATTERN TYPES OF FLOWERS

[The figures 31–39 in this section refer to the corresponding figures in the Frontispiece]

as will be realised when the carpel splits open later, as it does, *e.g.* in larkspur (*Delphinium*) or marsh marigold (*Caltha*). The ovules are destined to become the seeds, provided the pollen-grains are allowed the chance of performing their office. The lower ovule, containing part of a carpel is the *ovary*, and its narrow upper end is the *style*, on the top of which is a sticky patch, the *stigma*. The carpels are the female part of the flower, and are collectively termed the *pistil*.

Production of Seeds. In order to clearly understand how ovules become seeds it will be best to leave our pattern flower, and consider a still simpler case, where only one carpel is present, in which but one ovule is contained [**43**]. Microscopical examination will show us that this ovule is covered by two protective skins, imperfect, however, at one place—the *micropyle*, which is simply the Greek for "little gateway." Within these skins is a cellular mass (*nucellus*), one cell of which, close to the micropyle, has developed into a relatively conspicuous structure, and is known as the *embryo sac*, because within it the young plant is formed.

The most important part of the contents of this sac is the *egg-apparatus*, a group of three small cells next the micropyle. One of them, which is much larger than the others, is the *egg-cell*, or *ovum*, from which the young plant originates, and which is strictly comparable to the egg of a fish, a frog, or an insect. But its development cannot begin unless it is *fertilised*—*i.e.*, unless an infinitesimal amount of what may be called male protoplasm fuses with it. It is the office of the pollen-grain to supply this. And here it may be stated, once for all, that sexual reproduction in plants and animals alike essentially consists in the coalescence of two minute masses of living matter, or protoplasm, one male and the other female. We do not at present precisely know why fertilisation should be necessary, or exactly how it makes it possible for the egg-cell to develop.

The Birth of a Plant. [**43**]. A pollen-grain is a small mass of protoplasm containing two *nuclei*, and covered by two skins, of which the inner one is very delicate. It may be regarded as consisting of two cells—as indicated by the two nuclei—though in the higher seed-plants these are not separated from each other by a party-wall. The first step towards the attainment of fertilisation is the transfer of pollen-grains to the stigma. This is *pollination*.

Supposing this transfer to have been accomplished, the pollen-grain germinates in the sticky fluid of the stigma, and sends out an excessively delicate *pollen-tube*, which grows down through the style into the ovary, where its tip passes through the micropyle. Meanwhile, one of the two nuclei of the pollen-grain has passed into the pollen-tube, where it divides into several fragments. One of these enters the ovum, with the nucleus of which it fuses, and thus effects fertilisation. It has just been said that this process consists in the union of two minute masses of protoplasm, and we may add to this that the masses in question are of nuclear nature,—*i.e.* they are made up of *specialised* protoplasm. The nucleus of a cell is, in fact, of an extraordinarily complex nature, but it would take us too far to enter into details regarding this.

Supposing that the pollen-grain of our simple flower has been transferred to the stigma of the *same* flower, it will be a case of *self-pollination*, followed by *self-fertilisation*. But if the pollen-grains on the stigma have come from *another* flower we have *cross-pollination*, followed by *cross-fertilisation*.

How Insects Beautify the World. As a result of very numerous observations and experiments it has been clearly proved that healthier and more vigorous seeds are produced when cross-fertilisation takes place than when the egg-cells are self-fertilised. We do not quite know why, but such is the case. Pollen from another flower on the same plant is better than pollen from the same flower, while if it has been produced in a different plant of the same species the results are still more favourable.

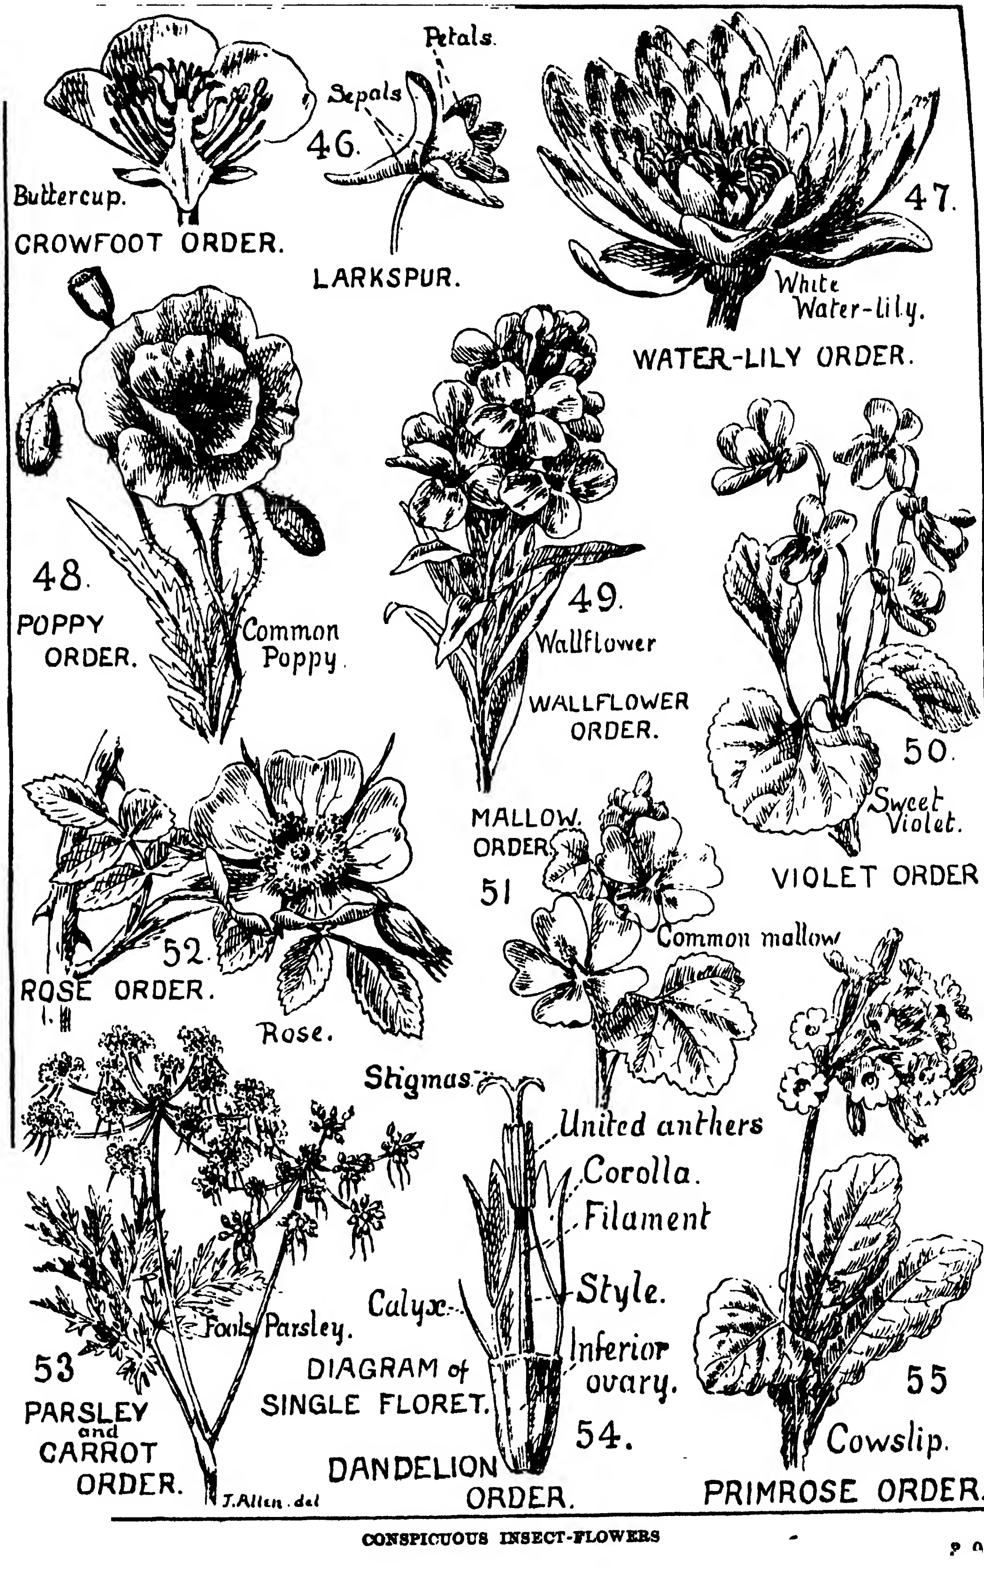
As cross-fertilisation is necessarily preceded by cross-pollination, we naturally expect to find many devices for securing this. Pollen may be transferred from one flower to another by various agencies. If we suppose our simple flower to be a *conspicuous* one, the transfer will most likely be effected by insects—*i.e.* it will be *insect-pollinated*.

The *colours* and *odours* of our native flowering plants are simply to be regarded as means for attracting insects, though fortunately enough these have for the most part similar predilections in these matters to ourselves. Indeed we may say that our æsthetic tastes, so far as sight and smell are concerned, have evolved to a large extent on lines determined by the insect world.

Flowers, however, do more than merely attract insects by suitable colours and odours. They provide them with what may be called *flower-food*, upon which indeed some of their guests are entirely dependent. This partly consists of the *pollen* itself, which is produced in abundance, and partly of the sweet fluid known as *nectar*. The latter oozes out from little swellings—*nectaries*—situated deep down in the flower, and varying a good deal in number, character, and exact position.

The fertilised ovum divides again and again to produce a small mass of cells, which enlarges and increases to form a minute plantlet, outside or within which is a store of food in the form of starch and albuminous matter, or possibly other nutritive substances which render growth possible till such time as the young plant is able to draw on the supplies of the outside world. The delicate investments of the ovule become firm and tough *seed-coats*.

The Fruit. While the seeds are ripening the ovary enlarges and becomes the *fruit*. This may be hard and dry, as in buttercup, poppy, and sunflower, or fleshy and succulent, as in plum, orange, and grape. Other parts besides the ovary may undergo changes, and contribute to the formation of what is then termed a "false fruit." The red pulp of a strawberry, for instance, is formed by the enlargement of the



CONSPICUOUS INSECT-FLOWERS

stem-part of the flower,—*i.e.* the receptacle. The little brown pips which stud its surface are the real fruit—in this case dry, and each formed from an ovary.

The diverse characters of seeds and fruits are often in relation to the necessity for giving the young plants a chance of finding some suitable spot in which to grow up, and for preventing them from competing too vigorously with their parents. We have, in fact, all sorts of arrangements by which the *scattering* or *dispersal* of seeds is facilitated.

Germination of the Seed [44]. If a bean is soaked in water and the tough coats removed, we shall find the interior entirely occupied by the young plantlet, which consists of a very small root (*radicle*), a shoot (*plumule*), and two relatively enormous seed-leaves (*cotyledons*), in which food is stored. By treating a castor-oil seed (easily obtainable from the chemist) in the same way, we shall also be able to make out radicle, plumule, and cotyledons, but these last are quite thin and do not act as storehouses. In this case the plantlet is embedded in a mass of nutritious substance, known as the *endosperm*, or often as the "albumen," a not very happy name for it. The two seeds named are types of *exalbuminous* and *albuminous* seeds, in which the food of the young plant is stored up within it and outside it respectively.

During the winter the seed remains in a dormant condition, but when spring arrives it begins to grow—*i.e. germinates*. The seed coats crack, the radicle elongates and pushes its way into the soil, while the plumule also becomes larger and longer, rising into the air and unfolding its leaves. The food store is gradually exhausted in these processes of growth, becoming converted into soluble substances, which travel to the places where they are required. By the time they are all used up the seedling plant is able to take its food from the air and soil. Moisture, oxygen, and warmth are required for germination.

CLASSIFICATION OF SEED-PLANTS

We have already seen that the seed-plant phylum (*spermophytes*) is divided into pod-plants (*angiosperms*) and naked-seeded plants (*gymnosperms*), and some details regarding the subdivisions of the former may now be given sufficient to serve as an introduction to special works on the subject. Pod-plants are divisible into two *classes*, as follow:

Class I. Dicotyledons. The seedling is provided with two cotyledons or seed-leaves, and the vascular bundles of the stem are arranged in a ring, each of them containing *cambium*, which is able to bring about increase in thickness. The veins of leaves are arranged in *net-like* fashion. Whorls of the perianth in 4's or 5's.

Class II. Monocotyledons. The seedling is provided with only one cotyledon, and the vascular bundles of the stem are scattered and devoid of cambium. The chief veins of the leaves are generally more or less parallel. Whorls of the perianth in 3's.

100,000 Species. As over 200 orders are recognised (of which about 90 are British), embracing something like 100,000 species, it is obvious that we must limit ourselves to the consideration of facts of leading importance.

The characters used in classification are of the most various kind, and though in most cases there is no doubt some practical meaning to be attached to them, our knowledge as to that meaning is often incomplete.

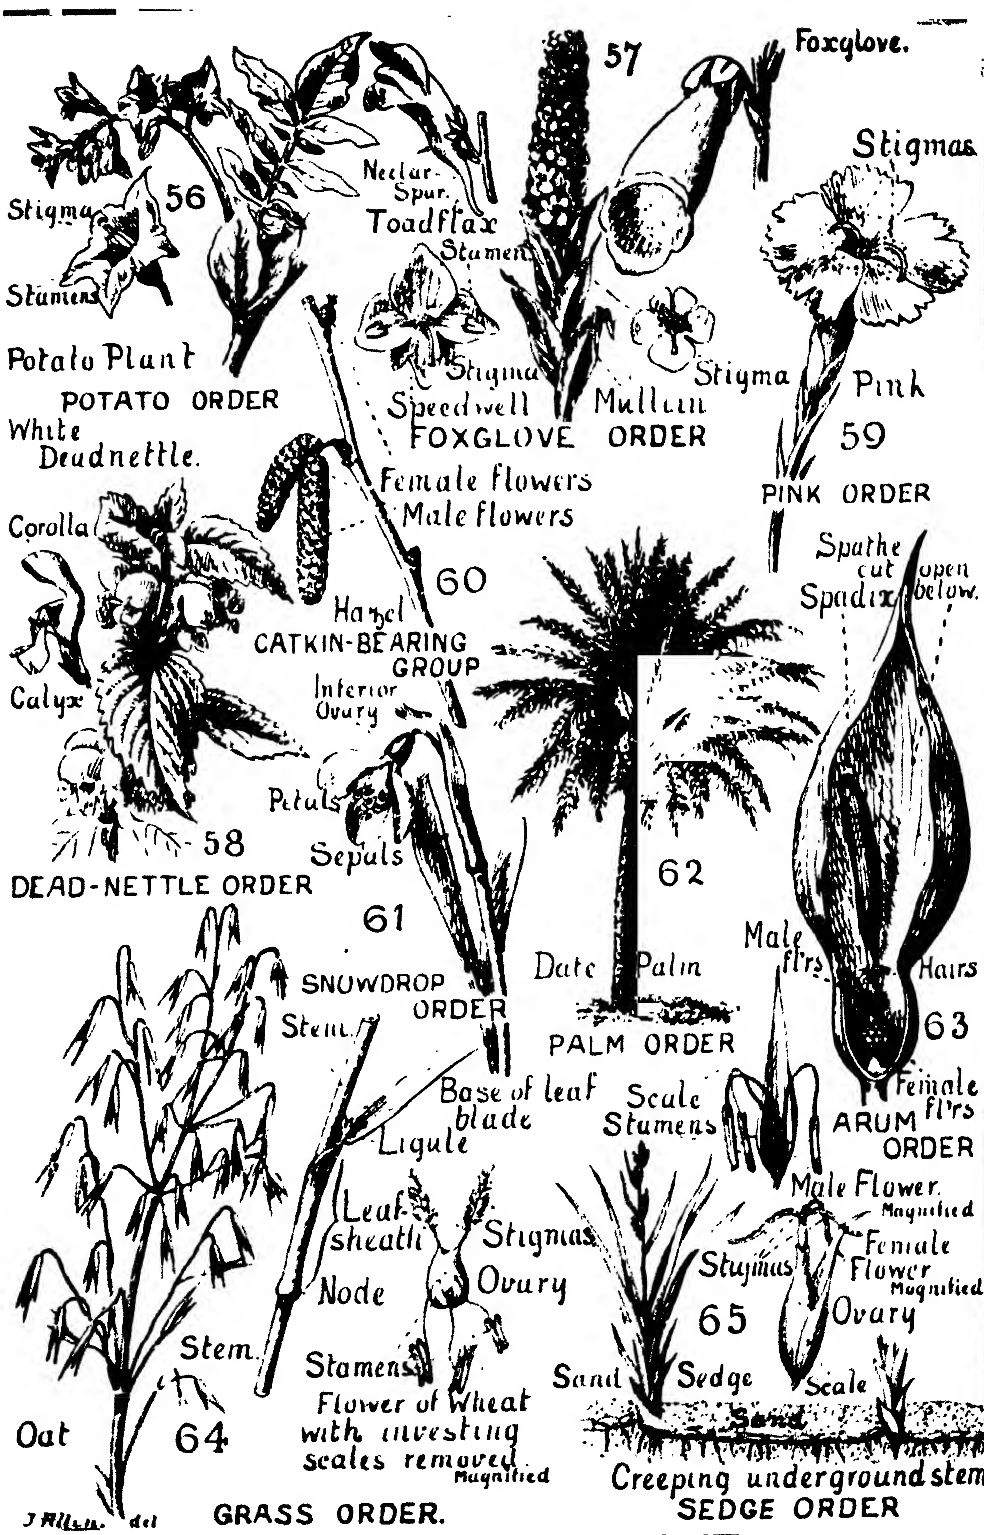
We find that *foliage-leaves* vary greatly in arrangement and shape; while stipules may be present or absent. As to the first point, which largely has reference to advantageous disposition with reference to light, we may find either only *one* leaf per node, the successive leaves being arranged in a spiral, or there may be *two* leaves at each node. In these two cases the leaves are said to be respectively *alternate* and *opposite*. The shape, as we have elsewhere seen, is often also related to the supply of light. In *simple* leaves the blade is one piece, in *compound* ones it is cut up into a varying number of distinct leaflets. Leaves devoid of stipules are said to be *exstipulate*.

The Structure of a Flower. Great importance attaches to the arrangement and structure of the parts of the *flower*, in which we can often detect some connection with the way in which pollination is effected. In our pattern flower the parts of each whorl of the perianth were all alike, and disposed in a starlike manner. Such a flower is *regular*. But in flowers which are pollinated by the higher insects, such as bees and butterflies, we find that these parts are more or less unequal, and disposed in a two-sided fashion. These are termed *irregular*—*e.g.* pea, pansy, and larkspur.

In simpler cases the *receptacle* is more or less conical, so that the sepals, petals, and stamens clearly spring from beneath the pistil. The flower is then *hypogynous*, as in our pattern case. But the receptacle may be modified into a sort of cup, from the edge of which sepals, petals, and stamens arise, while the pistil occupies the interior of the cup, as in the rose. Such flowers are *perigynous*. And if this cup fuses with the pistil, so that the sepals, etc., appear to grow from the top of the ovary, as in the snowdrop, the flower is *epigynous*, and is still further specialised. In the two first cases the ovary is only attached to the receptacle by its base, and is said to be *superior*, while in the last case the attachment is more extensive, and it is termed *inferior* [45].

The Parts of a Flower. There are many variations as to the *number* of flower leaves. The most primitive case is where they are relatively numerous, and arranged in a spiral. This is beautifully seen in the sepals, petals, and stamens of the white water-lily (*Nymphæa alba*), which pass gradually into one another; also in the stamens and carpels of buttercups (*Ranunculus*).

In most flowers, however, the parts are in successive whorls, as in our pattern case, but there are many variations as to number. The inner whorl of *stamens* is often suppressed



CONSPICUOUS INSECT-FLOWERS AND INCONSPICUOUS WIND-FLOWERS

altogether, and in extreme cases—*e.g.* most orchids—only one stamen may be present. Such reductions have reference to increasing certainty of pollination, so that there is no need for a large quantity of pollen to be produced. The *carpels*, too, for similar reasons, are often reduced in number, and many flowers—*e.g.* pea and gorse, possess but one.

The *perianth* is badly developed, reduced, and inconspicuous, or even absent, where pollination is not effected by insects (or birds), so that there is no need for conspicuousness. In such cases, there is usually an absence of colour (other than green), odour, and nectar.

In simpler cases the flower-leaves of a particular kind are not united together, *i.e.*, are *free*. With increasing specialisation we find sepals, petals, stamens, and more particularly carpels, are respectively *united*. Flower-leaves of different kind may also adhere together—*e.g.*, stamens with petals, as in primrose (*Primula vulgaris*).

There is further a great deal of variation as regards the number of *ovules*, and the way in which these are arranged in the ovary. *Seeds* may be either exalbuminous or albuminous, as already mentioned

We are now in a position to briefly summarise the characters of the more important subdivisions of Dicotyledons and Monocotyledons. The flowers are hypogynous and the ovary superior unless otherwise stated.

SEED-PLANTS.—CLASS I. [Dicotyledons.]

This class is divided into three sub-classes, the flowers belonging to the first two of which are commonly conspicuous, which means that they are pollinated by insects, or it may be in the warmer parts of the globe by birds.

SUB-CLASS 1. *Polypetalæ*. Both calyx and corolla present. Petals free.

a. Buttercup and Water-Lily Group (*Ranales*). Stamens generally numerous. Carpels usually free. Seeds albuminous.

1. CROWFOOT ORDER (*Ranunculaceæ*) [**46**]. Leaves generally alternate and exstipulate. The buttercups and their allies possess regular flowers, with numerous stamens and carpels, while in forms such as larkspur (*Delphinium*), and monkshood (*Aconitum*), there are showy irregular flowers specialised in relation to the visits of higher insects, and fewer carpels.

2. WATER-LILY ORDER (*Nymphæaceæ*) [**47**]. Marsh or aquatic herbs, such as white water-lily (*Nymphæa alba*), and yellow water-lily (*Nuphar luteus*), with conspicuous flowers, the spiral arrangement of which has already been mentioned. Notable species are the Egyptian lotus (*Nymphæa lotus*), and *Victoria regia*, a South American form, with leaves 6 ft. and flowers 16 ins. in diameter.

Barberry (*Berberis*) and magnolia belong to other orders of this group.

b. Poppy, Wallflower, and Violet Group (*Parietales*). The chief peculiarity of this group consists in the fact that the two or more carpels present are united together by their edges, so that the ovules are attached to the outer wall of the ovary.

3. POPPY ORDER (*Papaveraceæ*) [**48**]. Herbs yielding a sticky juice (*latex*), which is either milky in appearance or else coloured. Leaves alternate and exstipulate. Sepals, two; petals, four. Stamens numerous. The flowers are very conspicuous, and the numerous seeds are albuminous. Poppies are the best-known types, and the latex of one species (*Papaver somniferum*) is the source of opium. The greater celandine (*Chelidonium majus*), a common hedgerow plant, has yellow flowers, and yields an orange-yellow juice.

4. WALLFLOWER ORDER (*Cruciferæ*) [**49**]. In this large and important order the leaves are alternate and exstipulate. There are four sepals in two whorls, four petals arranged in the form of a cross, six stamens (four long and two short), and two carpels. The ovary is divided into two cavities by a partition growing out from the edges of the fused carpels. Seeds exalbuminous. Good examples of the order are wallflower (*Cheiranthus cheiri*) and stocks (*Matthiola*); also many common wild forms, such as shepherd's purse (*Capsella bursa-pastoris*), lady's smock or cuckoo-flower (*Cardamine pratensis*), and charlock (*Brassica sinapistrum*), a noxious weed of which the yellow flowers are seen in cultivated fields. Many species are used as food—*e.g.*, watercress (*Nasturtium officinale*), and garden cress (*Lepidium sativum*), which together with white mustard (*Brassica alba*), constitutes the familiar "small salad" or "mustard and cress." Cultivated radishes are derived from one wild species (*Raphanus raphanistrum*), turnips, swedes, and rape from another (*Brassica campestris*); while ordinary and red cabbage, cauliflower, Brussels sprouts, and savoys, have all been produced by cultivating the wild cabbage (*Brassica oleracea*)

5. VIOLET ORDER (*Violaceæ*) [**50**]. Leaves alternate, with stipules. The flowers are irregular and more or less conspicuous. The flower-leaves are in fives, except the carpels, of which there are three. Violets and pansies (*Viola*) are the best-known plants in the order.

Certain pitcher-plants (*Sarracenia*), yellow corydal (*Corydalis lutea*), the caper-plant (*Capparis*), of which the flower buds are used for caper sauce, rock-rose (*Helianthemum*), mignonette (*Reseda*), and the insect-eating sundews (*Drosera*), belong to other orders of the group.

c. Mallow Group (*Malvales*). The flowers are regular, and the parts of the perianth are in fives. Stamens variable in number, often united by their filaments. Carpels three or more, with the ovary in compartments.

6. MALLOW ORDER (*Malvaceæ*) [**51**]. Leaves alternate, with stipules. The filaments of the numerous stamens are united into a tube, and the carpels are also numerous. Seeds nearly or quite exalbuminous. Well-known examples are marsh-mallow and hollyhock (*Althæa*) mallows (*Malva*), the tree-mallow (*Lavatera*) which grows by the sea, and also the cotton-plant (*Gossypium*).

7. LIME ORDER (*Tiliaceæ*). Mostly trees or

shrubs with alternate stipulate leaves. The corolla is often reduced and inconspicuous. Seeds albuminous.

The lime or linden (*Tilia*) is visited by numerous bees, for though its flowers are not very conspicuous, they are exceedingly fragrant, and produce large quantities of nectar.

The Cocoa-tree (*Theobroma Cacao*) belongs to another order of the group, and so does the tea-plant (*Thea sinensis*).

d. Disk-flower Group (*Disciflorœ*). The chief distinctive feature of this large assemblage of plants is found in the fact that the single whorl of carpels is borne on a swelling of the receptacle, technically known as a "disk." It is in reality a nectary.

8. Flax Order (*Linaceœ*).—Leaves exstipulate. The flowers are regular, with four to five sepals, the same number of petals and stamens (there may be ten of the latter), and three to five carpels united together.

The order is mentioned here because it includes common flax (*Linum usitatissimum*), the bast-fibres of which are used in linen manufacture.

9. Geranium Order (*Geraniaceœ*). The parts of the flower are mostly in 5's, and the carpels are united. The upper part of the pistil is generally beak-shaped. Seeds nearly or quite exalbuminous. The crane's bills (*Geranium*) bear regular flowers, while those of the much-cultivated pelargoniums are more or less irregular, as are the stork's-bills (*Erodium*). Indian cress or "nasturtium" (*Tropœolum*) [33], and balsam (*Impatiens*). The delicate white flowers of wood-sorrel (*Oxalis acetosella*) are regular.

Rue (*Ruta*), oranges and lemons (*Citrus*), holly (*Ilex*), spindle-tree (*Euonymus*), vine (*Vitis*), Virginia creeper (*Ampelopsis*), maple and sycamore (*Acer*), and horse-chestnut (*Hippocastanum*), belong to other orders of the group.

e. Cup-flower Group (*Crateranthece*). The receptacle is either flat or to some extent cup-shaped, so that the flower is more or less perigynous. Sepals and petals in 4's or 5's.

10. Pea Order (*Leguminosœ*). Our native species of this large and important order possess alternate stipulate leaves, and irregular butterfly-shaped flowers [Wistaria, 36]. There are five united sepals and five petals, free except that the limbs of the lowest two are partly united. Stamens ten, with all their filaments united into a tube, or the uppermost one free. There is but a single carpel, which ripens into a pod that liberates its seeds by splitting down one side. The seeds are exalbuminous. The order is notable in many ways. Some of the included species do much to give colour to our landscapes, especially gorse (*Ulex europœus*), broom (*Cytisus scoparius*), and the clovers (*Trifolium*). Others are valuable fodder plants, as clovers, vetches, and horse-bean (*Vicia*), while many—*e.g.* pea (*Pisum sativum*), scarlet runner (*Phaseolus multiflorus*), broad bean (*Vicia faba*), and lentil (*Lens esculenta*) are important articles of food.

Exotic members of the order differing in many respects from the types already mentioned are the liquorice plant (*Glycyrrhiza*), indigo (*Indigofera*), and numerous species of acacia [32].

11. Rose Order (*Rosaceœ*) [34 and 52]. Leaves with stipules, and usually alternate. The regular, often conspicuous flowers possess five sepals, five petals, numerous stamens (as a rule), and a variable number of carpels, which may be free or united. Seeds exalbuminous, or nearly so.

This order is also large and very important. Among beautiful species roses (*Rosa*) and hawthorn (*Cratœgus*) are conspicuous, while the following yield edible fruits: plum, apricot, and cherry (*Prunus*), strawberry (*Fragaria*), pear and apple (*Pyrus*), quince (*Cydonia*), medlar (*Mespilus*), and peach (*Amygdalus*).

Saxifrages (*Saxifraga*), gooseberry and currant (*Ribes*), and stone-crop (*Sedum*) belong to other orders of the group.

f. Myrtle Group (*Myrtales*). As in the last group there is a cup-shaped receptacle, but this is in all cases fused to the ovary, which is therefore inferior.

Among familiar plants belonging to orders of the group are willow-herbs (*Epilobium*), evening primrose (*Œnothera*), and fuchsia, with the parts of the flower in 4's, while in the last the sepals are brightly coloured. Other examples are myrtle (*Myrtus*) and the related eucalyptus, which is an important Australian forest tree, and may be nearly 500 feet high. Pomegranate (*Punica*), Brazil nut (*Bertholletia*), and clove (*Eugenia*), of which the flower-buds are used as spice, also belong to this group.

g. Cucumber Group (*Pepones*). Regular flowers, some of which possess stamens and others carpels. Such male and female flowers may occur on the same or on different plants.

Cucumbers, melons, gourds, and allied plants constitute one order (*Cucurbitacea*) of the group, while the common garden plant begonia belongs to another (*Begoniaceœ*).

h. Cactus Group (*Cactales*). Here the leaves are reduced to scales or prickles, and their work is taken over by the thick green stems, which assume the most extraordinary forms. The very numerous flower-leaves are spirally arranged.

i. Parsnip and Carrot Group (*Umbellales*). The small flowers are epigynous and there is a fleshy nectary on the top of the inferior ovary. Seeds albuminous.

12. Parsnip and Carrot Order (*Umbelliferœ*) [53]. The small flowers are arranged in *umbels*—*i.e.* a number of flower-stalks radiate from the same point, and in this way conspicuousness is brought about, so that many insects are attracted.

A number of useful species belong to the order, such as caraway (*Carum carui*), carrot (*Daucus carota*), parsnip (*Pastinaca sativa*), parsley (*Petroselinum sativum*), coriander (*Coriandrum sativum*), and celery (*Apium graveolens*). Some species are very poisonous, especially the hemlock (*Conium maculatum*).

Ivy (*Hedera helix*) and cornel or dogwood (*Cornus sanguinea*) belong to other orders of the group.

Sub-Class 2. (*Monopetalœ*). The flowers possess both calyx and corolla. Petals united.

k. Madder and Honeysuckle Group (*Caprifoliales*). Foliage-leaves opposite, with stipules. Ovary inferior. Seeds albuminous.

Among plants belonging to this group are the following: Madder (*Rubia tinctorum*) once important as the source of a red dye-stuff, goose-grass or cleavers (*Galium aparine*), a common hedgerow plant, the coffee plant (*Coffea arabica*), cinchona, from the bark of which quinine is obtained, and honeysuckle (*Lonicera*), with conspicuous irregular fragrant flowers.

l. Star-flower Group (*Asterales*). Leaves exstipulate. The flowers are small, but being aggregated together in large numbers, are conspicuous. They are epigynous, and the inferior ovary contains but one ovule.

13. DANDELION ORDER (*Compositæ*). [54]. What looks at first sight like a single flower in a member of this order—*e.g.*, dandelion, really consists of a number of very small flowers (*florets*) crowded together into what is technically known as a "head," round which is a protective covering of bracts, liable to be mistaken for a calyx. The parts of the flower are in 5's, except the carpels, of which two are present, these being united. The stamens are attached to the corolla, and their anthers are united into a tube which surrounds the style. The calyx is greatly reduced, and often converted into a crown of hairs. Seeds exalbuminous. Among the most conspicuous of the very numerous plants belonging to this large and dominant order are sunflower (*Helianthus annuus*), aster, dahlia, cineraria, and chrysanthemum. Other well-known forms are dandelion (*Taraxacum officinale*), daisy (*Bellis perennis*), ox-eye daisy (*Chrysanthemum leucanthemum*), thistles, groundsel (*Senecio vulgaris*), and colt's-foot (*Tussilago farfara*). Valerian (*Valeriana*), teasel (*Dipsacus*), and scabious (*Scabiosa*) belong to other orders of the group.

m. Heath Group (*Ericales*). Flowers more or less conspicuous. Carpels three to ten, united. Ovary superior. Seeds albuminous.

14. HEATH ORDER (*Ericaceæ*). Evergreens with exstipulate leaves. Flowers nearly or quite regular. Ovules numerous. This order greatly contributes to the beauty of our moorland landscapes, for it includes heather (*Calluna vulgaris*), and the various kinds of heath or bell-heather (*Erica*). Azaleas [31] and rhododendrons are near relatives of these.

n. Primrose Group (*Primulales*). Flowers regular, with five stamens opposite the petals, to which they are attached. Carpels five, united. The superior ovary contains but a single cavity, and the ovules are attached to a projection on the floor of this. Seeds albuminous.

15. PRIMULACEÆ [55]. Leaves exstipulate. Flowers commonly conspicuous, with parts in 5's. Primrose (*Primula vulgaris*), cowslip (*P. veris*), and sow-bread (*Cyclamen*) are the most familiar members of the order.

Sea-thrift (*Armeria*) belongs to a related order.

o. Tube-flower Group (*Tubifloræ*). Sepals and petals 4–5, stamens 2–5, pistil of 2–5 united carpels. The superior ovary contains two or more compartments.

16. POTATO ORDER (*Solanaceæ*) [56]. Flowers regular, with parts usually in 5's, except the carpels, of which there are two. Numerous small albuminous seeds. The potato plant (*Solanum tuberosum*) and tobacco plant (*Nicotiana*) are of obvious importance, and valuable drugs are obtained from the virulently poisonous henbane (*Hyoscyamus niger*), deadly nightshade (*Atropa belladonna*), and thorn-apple (*Datura stramonium*). Petunias also belong here.

17. FOXGLOVE ORDER (*Scrophulariaceæ*) [57]. Flowers generally irregular and stamens four, though these are sometimes two or five. There are two compartments in the ovary. Seeds as in last order. The mulleins (*Verbascum*) possess nearly regular flowers (with five stamens), generally of yellow colour, and arranged in tall handsome spikes. The conspicuous flowers of foxglove (*Digitalis purpurea*) are arranged along one side of the main axis: the plant is exceedingly poisonous. The little blue speedwells (*Veronica*) possess but four petals and two stamens. Toadflax (*Linaria vulgaris*) and snapdragon (*Antirrhinum*) have irregular flowers of remarkable shape, which have to be forced open by visiting bees.

18. DEAD-NETTLE ORDER (*Labiatæ*). Leaves exstipulate and usually opposite. Stems four-sided. Flowers markedly irregular, with five sepals, five petals, four stamens (usually), and two united carpels. The ovary is deeply divided into four lobes, each of which contains an ovule. Seeds exalbuminous. The white and purple dead-nettles (*Lamium album* and *purpureum*), and ground-ivy (*Nepeta glechoma*) are common types. Many members of the order are aromatic, and yield essential oils. Among these may be mentioned mint (*Mentha*), sage (*Salvia*) [38], thyme (*Thymus*), marjoram (*Origanum*), and basil (*Ocimum*).

Gentians (*Gentiana*), periwinkle (*Apocynum*), convolvulus, forget-me-not (*Myosotis*), wild plantain (*Plantago*), verbena, gloxinia [37], ash (*Fraxinus*), and jessamine (*Jasminum*), belong to other orders of this extensive group.

SUB-CLASS 3. *Incompletæ*.—This is a large and somewhat heterogeneous assemblage of plants in which the flowers, as a rule, either possess no perianth at all, or one consisting of a single whorl of flower-leaves.

p. Central-seeded Group (*Centrospermæ*). Regular flowers, with superior ovary containing but one compartment, in the centre of which is a projection to which the ovules are attached.

19. PINK ORDER (*Caryophyllaceæ*) [59]. Leaves opposite. Contrary to the general rule for the sub-class, the flowers possess both calyx and corolla. Numerous small albuminous seeds. Common examples are pinks and carnations (*Dianthus*), campions (*Lychnis*), and chickweed (*Stellaria media*).

Pepper (*Piper*), docks (*Rumex*), beet (*Beta*), and nettle (*Urtica*), belong to other orders of the group.

q. Green-flowered Group (*Viridifloræ*). Small green regular flowers, with one or two carpels. The superior ovary contains a single ovule. The following belong to various orders of the group: Fig (*Ficus carica*), india-rubber plant (*F. elastica*), hop (*Humulus lupulus*),

hemp (*Cannabis sativa*), bread-fruit (*Artocarpus*), mulberry (*Morus*), and elm (*Ulmus*).

r. Catkin-bearing Group (*Amentales*) [60]. Shrubs or trees with flowers in catkins or heads. The stamens and carpels are in separate flowers, the male and female flowers being on the same or different plants. The perianth is usually wanting, for in most cases there are no insect visitors. The following are common examples of the group: Poplar (*Populus*), willow (*Salix*), oak (*Quercus*), beech (*Fagus*), hazel (*Corylus*), hornbeam (*Carpinus*), birch (*Betula*), alder (*Alnus*), walnut (*Juglans*), and chestnut (*Castanea*).

SEED-PLANTS. CLASS 2. [Monocotyledons.]

s. Lily Group (*Liliiflorœ*). The flowers are regular, with parts in three's, and the carpels are united. In most cases both sepals and petals are either white or brightly-coloured. Seeds, albuminous. There is generally a thickened underground stem.

20. LILY ORDER (*Liliaceœ*). Stamens six in number and ovary superior. The order includes many ornamental plants such as lily (*Lilium*) [35], tulip (*Tulipa*), squill (*Scilla*), hyacinth (*Hyacinthus*), lily of the valley (*Convallaria*), and "red-hot poker" (*Kniphofia*). Also asparagus, and the useful but malodorous onion, garlic, leek, and shallot (species of *Allium*). New Zealand flax (*Phormium tenax*) is of considerable economic importance. Nearly all members of the order are herbs, but to this there are exceptions, *e.g.*, yucca, and the dragon-tree (*Dracœna*) of the Canary Islands, which grows to an enormous size, and is very long-lived.

21. RUSH ORDER (*Juncaceœ*). Plants with narrow leaves and small brown inconspicuous flowers resembling those of the last order in structure. Rushes (*Juncus*) and wood-rushes (*Luzula*) are included here.

22. SNOWDROP ORDER (*Amaryllidaceœ*) [61]. As Order 20, but with an inferior ovary. Snowdrop (*Galanthus nivalis*) and daffodil (*Narcissus*), are examples.

23. IRIS ORDER (*Iridaceœ*). As last order, but only three stamens. Iris, crocus, gladiolus, and saffron (*Colchicum*) are good examples.

The pineapple (*Ananassa sativa*) belongs to another order of the group.

t. Banana Group (*Scitamineœ*). Tropical plants with large leaves and irregular flowers, of which the inferior ovary is generally divided into three compartments. The following plants belong to orders of this group. Banana (*Musa sapientum*), plantain (*M. paradisiaca*), ginger (*Zingiber*), Indian-shot (*Canna*), and arrowroot (*Maranta*).

u. Orchid Group (*Gynandrœ*). Flowers irregular and of remarkable form. The stamens are reduced in number and united with the pistil.

24. ORCHID ORDER (*Orchidaceœ*) [39]. This is the second largest order of seed-plants, only being excelled in size by the Compositæ, and including over 8,000 species. There is usually but one stamen. We have a few British orchids, but the headquarters of the order are in the tropics.

v. Aquatic Group (*Fluviales*). Aquatic forms, in which the stamens and carpels are commonly more numerous than in other Monocotyledons. The ovary is usually superior. The following are examples of orders of the group. Water-thyme (*Elodea*), water-soldier (*Stratiotes*), frog-bit (*Hydrocharis*), flowering-rush (*Butomus*), water-plantain (*Alisma*), arrowhead (*Sagittaria*), pond-weed (*Potamogeton*), and sea-grass (*Zostera*).

w. Palm and Arum Group (*Spadiciflorœ*). The stamens and carpels are generally in separate flowers, which are small and crowded together on fleshy axes, and protected by a sheath (*spathe*) that covers them. Ovary superior.

25. PALM ORDER (*Palmaceœ*) [62]. Large woody plants, nearly all of which are tropical. The large leaves commonly form a tuft on the top of a long cylindrical stem. The flowers are inconspicuous. Stamens six; carpels, three, united. Seeds albuminous, and not more than three in number. Two familiar and useful species are the coco-nut palm (*Cocos nucifera*), which attains a height of about 80 ft., and the date-palm (*Phœnix dactylifera*). Palm-oil, sago, vegetable ivory, and rattan canes are obtained from other members of the order.

26. ARUM ORDER (*Aroideœ*) [63]. Mostly tropical plants, of which the minute flowers are borne on a fleshy, brightly-coloured axis (*spadix*), the spathe surrounding which is often showy. Perhaps the best-known example of the order in this country is the so-called arum-lily (*Richardia æthiopica*), in which the spathe is white and the spadix orange-yellow. Our one native species, cuckoo-pint or "lords and ladies" (*Arum maculatum*) has arrow-shaped leaves blotched with black, a green spathe, and a dark-red spadix.

x. Grass and Sedge Group (*Glumiflorœ*). Inconspicuous flowers in which the perianth is absent or reduced. Groups of them are enclosed in and protected by scaly bracts.

27. GRASS ORDER (*Gramineœ*) [64]. Herbs with hollow-jointed stems (*haulms*), and alternate narrow leaves, the bases of which are in the form of sheaths grasping the stem and split down one side. There is a little membranous outgrowth (*ligule*) at the junction of blade and sheath. Stamens usually three and carpels two, united. The superior ovary contains a single ovule. The seeds are albuminous. All grasses are included here, as well as our cereal crops, *e.g.* wheat (*Triticum vulgare*), barley (*Hordeum sativum*), and oats (*Avena sativa*). The bamboo (*Bambusa*) and sugar-cane (*Saccharum*) are also members of the order.

28. SEDGE ORDER (*Cyperaceœ*) [65]. These differ from grasses in the possession of solid stems, while the leaf has no ligule and its sheath is not split. The members of the order abound in marshy places, and are common on the edges of streams, ponds, and lakes. The papyrus of the ancient Egyptians was prepared from the pith of one species (*Papyrus antiquorum*).

MATERIALS OF CONSTRUCTION

Copper, Tin, Lead, Zinc, Aluminium, Bronzes, Brasses, and other Alloys of the above. Solders. The lesser used Metals. Metalloids

By Professor HENRY ADAMS

Copper. The use of copper (*Cuprum*; symbol Cu; atomic weight 63) dates from very early times, probably because it frequently occurs in a native metallic state, either in detached masses, as on the southern shores of Lake Superior, or in veins disseminated through granite, etc., as in Cornwall and Wales. It is too tough to be blasted, and has therefore to be cut into portable blocks by the laborious use of chisels.

There are several ores of copper, as the red and black oxides, the green carbonates, and, most abundant of all, the yellow ore known as copper pyrites, consisting of copper, iron, and sulphur. Grey copper ore is also abundant and contains the same elements together with antimony and arsenic. The smelting of copper ore consists of several processes: (1) Roasting, to expel the arsenic and part of the sulphur and to convert the iron into oxide of iron. (2) Melting, to remove the oxide of iron in combination with silica, leaving a coarse metal consisting chiefly of sulphide of copper. (3) Calcining the coarse metal to remove more of the iron and sulphur. (4) Fusing of the calcined coarse metal to remove the remainder of the iron and produce *fine metal*. (5) Calcining or roasting the fine metal to remove the sulphur and obtain blistered copper. (6) Refining and toughening to purify the copper. In the latter process about six or eight tons of blistered copper are loosely piled upon the hearth of a melting furnace [38 and 39], so that the air may circulate freely through it.

Toughening. The oxygen of the air combines with the remaining sulphur and arsenic to form sulphurous and arsenious acid gases, and with the iron and other metallic impurities to form oxides. In about six hours the metal is melted and the slag formed upon the surface is raked off. The copper is then ready for toughening. To effect this the surface is covered with wood-charcoal, or with pounded anthracite, to protect it from further oxidation, and the molten metal is then stirred with a pole of green wood (usually birch). The end is kept under the surface and carbonic acid gas is disengaged until all the oxygen is driven off. Experience tells the men when the copper has attained its *tough pitch*. If the poling is carried on too long, the copper is called *overpoled*, and is then brittle and of an orange colour, of no use for working as copper, but good for brazing spelter. When the copper is intended to be rolled into sheets, a small quantity of lead is added, and stirring renewed to convert the lead into an oxide which rises to the surface and brings with it the oxides of any foreign metals, and is then skimmed off.

Characteristics of Copper. Copper is well known by its distinctive reddish colour; it is very soft and malleable, is also ductile, and is capable of a high polish. The malleability is increased by heating up to a certain temperature, but when heated to nearly melting point, it becomes very brittle. Advantage is taken of this property in foundries, where copper requires to be broken up to get the right proportions of copper and tin, or other metal, for casting. When hammered and rolled, copper becomes rigid, stiff, and hard. To cure this it is heated in a large chamber with flame passing through it, but as air is present, scale is formed. To get this off it is brushed over with common urine, heated again and dipped in water, when it all comes off clean. When sheet copper is exposed to the atmosphere on roofs, a green protecting film of carbonate of copper is formed, and no further action takes place. The thickness known as 24 B.W.G., weighing one pound per square foot, is generally used and its only disadvantage is its first cost. Being a good conductor of heat, it is used in thicker plates for locomotive fireboxes, but it loses tenacity in proportion to the rise of temperature. In the form of wire it is used for bell pulls and electrical conductors, and in the form of tape, averaging one inch wide and one-eighth of an inch thick, for lightning conductors. It is most largely used, however, alloyed with other metals, a great variety of properties being thereby developed that will be described presently.

Tin. Tin (*Stannum*; symbol Sn; atomic weight 118) is extracted from an ore called tinstone, consisting of oxide of tin, and found in Cornwall from the most remote times to the present day. It occurs as *mine tin ore* in veins traversing rocks of quartz, granite, or clay-slate, with other metallic impurities, and as *stream tin ore* mixed with mineral matter deposited by torrents in the valleys adjacent to the veins of mine tin ore. The marketable tin is prepared from the raw ore by the following operations: (1) Mechanical preparation of the ore. (2) Calcining or roasting. (3) Washing the roasted ore. (4) Smelting. (5) Refining.

The ore when raised from the mine is roughly freed from earthy matter by washing upon a grating, then broken and picked over to remove copper and iron pyrites, and crushed in a stamping mill [40]. It then goes through further washings on a buddle and other apparatus, where advantage is taken of the high specific gravity of tinstone to separate it from the impurities with which it is associated. The ore is next calcined in a reverberatory furnace with very long horizontal flues in which the oxidised arsenic

PROCESSES IN EXTRACTING METALS FROM THEIR ORES

is deposited as white arsenic. Part of the sulphur passes off as sulphurous acid gas and part combines with the copper and oxygen to form sulphate of copper. The roasted tin ore is then stirred in water to dissolve the copper sulphate, and washed on a rack to remove the oxide of iron, leaving *black tin*, which is smelted in a reverberatory furnace with a little lime to form a flux. The flux or slag is raked off the top and the molten tin runs into a pan and afterwards into cast-iron ingot moulds. The ingots of tin so obtained still contain a large proportion of impurities and are refined by operations known as *liquation* and *boiling*. The former consists of melting out the tin from a number of ingots and collecting the purer metal into a *refining basin*. The boiling consists of plunging stakes or logs of wet wood into the molten metal, which is kept hot by a separate fire, the steam given off causing the appearance of boiling and carrying the impurities to the surface in a froth which is skimmed off. It will be noticed that in every operation some of the material remains in a state of considerable impurity, and this being collected, is again passed through the process, so that in time it all comes to a final marketable state.

Tin Plate. Tin is so little affected by exposure to the air or the action of weak acids that it is used as a coating to protect other metals. Tin-plate and block tin are thin sheet-iron plates pickled, annealed, scoured to remove all oxide, and immersed in a cast iron pot containing melted tin covered with three or four inches of tallow; they remain in long enough for the tin to form an alloy with the surfaces of the iron, so that firm adhesion is secured. They are then immersed in molten tin of high purity, brushed and plunged into melted tallow, when the surplus tin runs to the lower edge and is afterwards removed. The plates, after being cleaned with bran, are packed in boxes containing from 100 to 225 sheets. Block tin has not only a thicker coating, but the entire surface is gone over with a polished hammer upon a polished anvil to improve the union between the two metals and stiffen the plate. Copper culinary utensils are very readily coated with tin and are then safe for domestic use; when uncoated, a portion of the copper is liable to be converted into acetate of copper or verdigris, which is dissolved, and the food prepared in such vessels becomes poisonous. Tin has the curious property of creaking when a small bar of it is bent, called the "cry of tin," but it is not used in a natural state except as a lining to lead pipes. It enters largely into alloys.

Lead. Minerals frequently contain lead (*Plumbum*; symbol Pb; atomic weight 206), but practically only one of them is used for the production of this metal—*viz.* Galena or sulphuret of lead (PbS), which has a crystalline form and striking lead-like lustre. It occurs in veins traversing the clay slate in Cornwall, the limestone in Derbyshire and Cumberland, and the granite in Spain, and is also found elsewhere. It usually contains a small portion of silver, which pays for extraction when it reaches two parts per 1000. The ore is broken or crushed, washed, and sorted before passing into a reverberatory furnace [41 and 42]. It there goes through four stages known as the first, second, third, and fourth fires. The fresh ore is put into the furnace while still hot from the previous charge, and a little coal is thrown into the furnace from time to time to keep up a moderate heat to roast the ore, from which some metallic lead runs through the tap-hole. At the end of two hours the furnace damper is raised, more coal is added to increase the temperature, some lime is thrown on the oxide and sulphate of lead upon the hearth, and the melted lead runs out freely. After about an hour the temperature is still further raised for another hour, the slags being spread over the hearth and more lime added. In the final stage the furnace is raised to its highest temperature, the metal run out on one side, and the slag is raked out on the other, leaving the furnace ready for a new charge of ore. The collected metal goes next to an improving furnace, which is a reverberatory furnace with a low arch, whence it is run into an iron pot and transferred to pig moulds. Foreign lead is re-melted in a large copper pan and run into half-round troughs, each containing one hundredweight, to form pig-lead.

Characteristics of Lead. Metallic lead is a bluish grey, with a lustre which is bright when freshly cut, but rapidly tarnishes on exposure to the air, is very soft, can be cut with wood-working tools, but clogs the file, is easily indented, very malleable, and only feebly ductile. Surfaces freshly cut can be welded at ordinary temperatures by simply pressing them firmly together.

When lead is melted in presence of air a greyish powder of sub-oxide is formed on the surface. If stirred vigorously for some time a yellow powder of protoxide of lead (PbO_2) will be formed, called massicot or litharge. Flint glass is composed of yellow oxide of lead, silica, and potash. Lead in large proportion gives great brilliancy to the glass, and the so-called paste gems are thus made. If the heating be further prolonged red lead will be produced. The reduction of oxide of lead—*i.e.* the removal of the oxygen—is very easy; it is only necessary to melt it in contact with charcoal, coal, or coke dust ($2\,PbO + C = 2\,Pb + CO_2$).

Sheet Lead. Sheet lead may be cast in sheets 16 to 18 ft. long, 6 ft. wide, and about ⅛ in. thick, by melting pig-lead and pouring it on to a level sand-bed on a wooden bench, and sweeping off the surplus with a "strike." It is, however, usually made by casting a thick block weighing 4 to 6 tons and passing it under metal rollers until it is reduced to the thickness required. The sheets are from 24 ft. to 36 ft. long and 5 ft. to 8 ft. wide, the finished thickness varying from $\frac{1}{20}$ in. to $\frac{1}{16}$ in. thick, but generally known by the weight in pounds per foot super, say 3 lb. to 10 lb. It is much used in roof work, 4 lb. or 5 lb. lead for aprons, flashings, and soakers, 5 lb. to 7 lb. lead for hips and ridges, 6 lb. to 8 lb. lead for gutters and flats, and wherever it is liable to be walked upon, 7 lb. to 8 lb. for soil pipes. The weight in pounds per foot super multiplied by

0·017 will give the thickness in decimals of an inch.

How Lead Pipes are Made. Lead pipes are made in a hydraulic press, one form of which consists of a steel cylinder [43], containing molten lead from which the scum has been removed and having a rod equal to the required inside diameter of pipe standing up in the centre. This is raised by water pressure to meet a fixed ram of the same diameter as the inside of the cylinder, and with a die in the bottom having a hole equal to the outside diameter of pipe. When the lead has just set, the cylinder containing it is forced upwards, and the lead squirting through the annular space in the bottom of ram forms a continuous pipe, which is coiled on a wooden drum. Lead pipes must not be used for the conveyance of soft water, although the water itself does not act upon the lead; it holds in solution some of the oxygen of the air, and this converts a portion of lead into oxide of lead, which is very poisonous, and accumulates in the human system, giving rise to colic and paralysis. Hard water does not have the same effect, as some of the carbonates contained are deposited on the lead and protect it.

Zinc. Zinc (symbol Zn.; atomic weight 65) is found to a limited extent in England as zinc sulphide, called *zinc blende* or *black jack*, and *zinc carbonate* or *calamine*. The blende is stamped to powder and washed to free it from earthy matters, calcined in a reverberatory furnace with a double hearth, being first roasted on the cooler portion near the chimney and then on the hotter part near the furnace. The roasted ore used to be distilled with coke in fire clay crucibles arranged round a furnace like a glass furnace [46]. Each crucible had a pipe leading from the bottom, in which the zinc was condensed and passed into a receiver. A considerable quantity of oxide was carried down with the zinc, and the whole was re-melted in an iron pot, skimmed, and cast into flat cakes or ingots of spelter. The Belgian process is, however, now generally employed in England. The mixed ore and coal are put into fire-clay cylinders of about 8 in. diameter and 3 ft. long, closed at one end. From 40 to 80 of these cylinders are ranged in a furnace [44] in tiers like gas retorts. The carbon of the coal unites with the oxide of the zinc and escapes as carbonic oxide, leaving the metallic zinc to come off as a dense vapour, which is condensed in cast iron conical tubes, from which it is raked out into a large iron ladle. The zinc is then skimmed from dross and cast into ingots of 70 lb. to 80 lb. each. In the Silesian process the calcined calamine is distilled with coal or coke in large retorts or muffles arranged in a furnace building as in 45.

Characteristics of Zinc. Zinc is a bluish metal, probably the "kuanos" of Homer, pliable and moderately soft. At a temperature of 200° to 250° F. it is rendered malleable and may be rolled into thin sheets. For this purpose the crude ingots are re-melted and cast into purer ingots of convenient size for rolling and passed between cast iron rolls. Sheet zinc is extensively employed for cheap gutters, rain-water pipes, baths, and roofing, for which it is eminently fitted by its resistance to the action of air and moisture. It soon tarnishes by the formation of a thin film of oxide, which preserves it from further action, but it has one serious defect for roofs, as it blazes fiercely under the action of fire, producing light white flakes of oxide of zinc which form the basis of a paint called zinc-white. The acids in the air of towns act freely upon zinc and corrode it. This is also liable to occur on flat roofs, to which cats have access.

Zinc, like copper, becomes very brittle if worked much with a hammer, but this may be obviated by annealing or heating it and allowing it to cool very gradually. Bronze, however, requires to be cooled quickly to anneal it. If the zinc be heated to just below melting point and cooled gradually it becomes very brittle, so that care has to be taken not to overheat it. Like tin, if bent backwards and forwards, it crackles.

Galvanised Iron. Galvanised iron is sheet iron coated with zinc by immersing it when thoroughly cleansed into melted zinc covered with powdered sal-ammoniac. The term "galvanised" arises from the original process of depositing the zinc on the iron plate by immersing the plates in a solution of sulphate of zinc and connecting them to the wires from the negative pole of a galvanic battery. The plates are generally corrugated to give them stiffness, and go by the name of corrugated iron, frequently used for covering temporary sheds. This material is ill adapted for use in towns, as the acids of the atmosphere attack the zinc, exposing the iron and allowing it to rust into holes. It is generally supposed that zinc is very light, but it is only seemingly light from the thinness of the sheets. Its weight is practically the same as that of cast iron.

Aluminium. Aluminium (symbol Al; atomic weight 27), discovered by Wöhler in 1828, is probably the most abundant of all metals, as it exists in every variety of clay (*silicate of alumina*). It is more easily obtained from some of its ores, such as bauxite. The ground mineral is mixed with soda-ash and heated in a reverberatory furnace, when the soda combines with the silica and alumina, forming silicate of soda and aluminate of soda, the carbonic acid being expelled as gas. The mass, after cooling, is treated with water to dissolve the aluminate of soda, which is then mixed with hydrochloric acid to remove the soda, leaving a gelatinous precipitate of hydrate of alumina. This is mixed to a stiff paste with common salt and charcoal powder, made up into balls the size of a fist, dried, and heated in earthenware cylinders through which chlorine gas is passed. The carbon of the charcoal combines with the oxygen of the alumina and escapes as carbonic oxide gas, while the aluminium unites with the chlorine to form chloride of aluminium; this combines with the salt (*chloride of sodium*) to form a double chloride of aluminium and sodium, which distils over and condenses to a solid mass. It is then mixed with sodium and fluor spar to form a slag to protect the metal, and thrown upon the red-

hot hearth of a reverberatory furnace, which is immediately closed to exclude the air. The sodium abstracts the chlorine and frees the aluminium, which collects in a melted state below the slag. Aluminium is now made at a tenth of its former price, and is coming largely into use for domestic utensils and a great variety of ornamental articles.

Characteristics of Aluminium. It is a white malleable metal about as hard as zinc, and fuses at a somewhat lower temperature than silver. It is extremely light and does not tarnish on exposure to the air. In appearance its colour is about midway between the two metals, zinc and silver. It is used extensively in alloys.

Bronze. Bronze is a mixture of copper and tin in various proportions, say, ten copper to one tin. Gun metal is a bronze with a little zinc in it. The following table gives the principal bronze alloys:

Name.	Copper.	Tin.	Zinc.
Soft gun-metal	16	1	—
Mathematical instruments	12	1	—
Pumps (very tough)	32	3	1
Pump plungers	14	1	1
Small toothed wheels	10	1	—
Locomotive bearings	64	7	1
Engine bearings	112	13	½
Locomotive straps and glands	130	16	1
Admiralty mixture for valves and mountings	90	10	2½
Hard gun-metal for bearings	8	1	—
Bally's metal	32	5	2
G. M. for heavy bearings	32	5	1
Maximum hardness for bearings	5	1	—
Hydraulic valve faces	4	1	—
Tam-tam (Chinese gongs)	4	1	—
Bell metal	3 to 5	1	—
Speculum metal	2	1	—

Other Bronzes. Aluminium bronze consists of 90 parts of copper to 10 of aluminium. Delta metal consists of 53½ parts of copper, ½ part of tin, 41½ parts of zinc, 1 part of lead, 1 part of iron, and ½ part of manganese. Phosphor bronze consists of 82 parts of copper, 10 parts of tin, 7½ parts of lead, ½ part of iron, ½ part of nickel, ½ part of phosphorus.

Brass. Brass is a mixture of copper and zinc in various proportions, say, for high brass, two copper to one zinc, and low brass four copper to one zinc. The terms *higher* and *lower*, applied to brass, express the greater or less quantity of zinc in the composition. The following table gives the principal brass alloys:

Name.	Copper.	Zinc.	Tin.	Lead.
Tough for engine work	100	15	15	—
For turning and fitting	8	1	—	$\frac{1}{16}$
Soft for hammering	7	3	—	—
Yellow brass	2	1	—	—
Stop-cocks and valves	88	10	2	—
Rolling-stock bearings	77	—	8	15
Flanges for brazing	32	1	—	1
Brass for soldering	8	3	—	—
Brass, various	60 to 92	8 to 40	½ to 3	½ to 3
Muntz metal sheathing	3	2	—	—
Do. locomotive tubes	66	33	—	1
Nails for sheathing	87	4	9	—
Statuary bronze	90	5	2	—
Red brass (Tombak)	8 to 10	1	—	—
Red sheet brass (German)	11	2	—	—
Bronze for lamps	27	6	1	1

Antimony. Antimony (*Stibium*; symbol Sb; atomic weight 122) is used in alloys for type founding, and for making antifriction metals. Type metal consists of three to seven parts of lead and one part of antimony. For stereotype metal a little bismuth is added to reduce the temperature of fusion. Hard antifriction metal consists of one part of copper, 50 parts of tin, and five parts of antimony. For soft antifriction metal the copper and tin are omitted and lead is added.

Nickel. Nickel (symbol Ni; atomic weight 59) is also used in alloys, chiefly in the manufacture of German silver and electro plate, consisting of copper, zinc, and nickel. It also enters into the composition of phosphor bronze and a variety of steel.

British Coinage. The bronze coinage consists of 95 parts copper, four parts tin, one part zinc. Three pennies weigh one ounce avoirdupois and a halfpenny is exactly one inch in diameter. It is proposed to use a nickel alloy instead of this mixture, as is done by many continental nations. The silver coinage consists of 7½ parts copper and 92½ parts silver. The gold coinage contains 91⅔ per cent. of pure gold, and the remainder copper. Pure gold is almost as soft as lead, and the addition is for the purpose of making it harder and more fusible.

Fusible Alloys. Alloys containing bismuth are called fusible alloys. According to the proportion used of lead, tin and bismuth, the melting point may be made to vary from 472° F. for bismuth alone to 200° for a mixture of one lead, one tin, and four bismuth. It will be noted that this is lower than the temperature of boiling water.

Solders. These are moderately fusible alloys used for joining metals. Plumbers' fine solder consists of one part of tin to one part of lead. Plumbers' coarse solder, one part of tin to three parts of lead. Tinmen's fine solder, three parts of tin to one part of lead. Tinmen's coarse solder, two parts of tin to one part of lead. Hard spelter for brazing, three parts of copper to one part of zinc. Soft spelter, one part of copper to one part of zinc.

Autogenic soldering consists of directing a flame of hydrogen along the edges of lead plates so as to melt and unite them without the use of solder. This method is chiefly used in joining plates for forming sulphuric acid chambers, as the ordinary solder would be rapidly eaten away by the acid attacking the tin. Sulphuric acid has no action upon lead.

THE LESSER USED METALS

Gold. Gold (*Aurum*; symbol Au; atomic weight 196) is found only in the metallic state, and exists practically in all parts of the world, but in the majority of cases its quantity is too small to pay for its separation. It is mostly disseminated in fragments and branches through quartz rock, but is also found largely in streams and sands, where it has evidently been produced by the crumbling of the rocks containing it, which have been worn away by the action of the water, leaving the gold deposited by reason of its great weight. It is generally extracted by

crushing and washing the auriferous quartz, or washing the sands containing it, the separation being effected by the difference in the specific gravity of the gold and the other matters. It is also obtained by the process of amalgamation with mercury, which dissolves the gold, and other processes are used according to the richness and nature of the matrix in which it occurs. Pure gold is uninfluenced even by strong acids, but can be dissolved by a mixture of nitric and hydrochloric acids. Its permanence arises from its resistance to combination with oxygen and sulphur, and it is only the minuteness of the particles rubbed off in its wear that causes its ultimate disappearance. It is too soft for use in its pure state, and hence for coinage is alloyed with $8\frac{1}{3}$ per cent. of copper. The presence of lead or antimony, even in very minute proportions, renders gold extremely brittle. The fineness or purity of gold is expressed by the number of carats of pure gold in 24 carats of alloy. Pure gold would thus be 24 carats fine and sovereign gold 22 carats fine. This latter is the highest degree of purity used by jewellers and is confined to wedding rings. For other purposes 18 carat gold is generally used, the alloy being gold, silver, and copper. The lowest degree of purity used under the name of gold jewellery is nine carats fine.

Malleability of Gold. Gold is the most malleable metal. It may be extended by beating to 650,000 times its original surface, the average thickness being $\frac{1}{282000}$ of an inch.

Gold leaf is made from a small ingot of pure gold weighing two ounces; this is annealed and hammered until it is reduced to one-sixth of an inch thick, and is then passed between steel rollers and annealed as often as may be necessary until it is formed into a riband weighing only six and a half grains per square inch. It is then cut up into pieces one inch square, which are piled up alternately with pieces of vellum four inches square. The beating is performed with a 16 lb. hammer, having a convex circular face four inches diameter. After various manipulations, and when the gold has been extended to twice the width each way, each leaf is cut into four equal parts of one square inch each. These are now placed between alternate layers of gold-beaters' skin and beaten with a 10 lb. hammer until they are each extended to about four inches square. These are again cut into four equal parts, put between gold-beaters' skin and hammered out with a 7 lb. hammer until they are about three and a half inches square. The gold leaves are then cut to exact size and packed between paper rubbed over with red chalk to prevent sticking, and made up in books of twenty-five. Mechanical power is sometimes substituted for hand labour.

Silver. Silver (*Argentum*; symbol Ag; atomic weight 108) is found in a native metallic state like twigs or branches of silver crystals strung together. It also occurs in combination with sulphur, chlorine, bromine, iodine, and associated with other metals in various ores, such as copper, zinc, and lead. Pure silver is soft and readily tarnished on exposure by reason of its affinity for sulphur in the sulphuretted hydrogen of the atmosphere of houses. Standard silver, as used for the silver coinage, is alloyed with copper to harden it, and a considerable quantity of copper may be added without altering the colour. The hardest alloy contains four silver to one copper. Standard silver is whitened by heating it until the oxygen of the air has converted a little of the copper at the surface into oxide, which is then dissolved by immersion in weak sulphuric acid or by other means, and is brightened by burnishing.

Electro Plating consists of depositing pure silver or other metal upon a baser foundation by means of a galvanic battery. The articles are suspended in a solution of cyanide of silver in cyanide of potassium, by wires connected to the last zinc plate of the battery, and the last copper plate of the battery is connected with silver plates suspended in the silvering liquid. The current from the battery causes the decomposition of the cyanide of silver in the solution, the silver being deposited upon the suspended articles, and the cyanogen set free combines with the silver of the suspended plates, forming fresh cyanide of silver and keeping the solution always at full strength. Simply, the operation consists in the transfer of silver from the suspended plates to the suspended articles through the intervention of the liquid and by means of the electric current.

Silvering on Glass. This may be effected by the precipitation of silver from a solution by chemical agents, and this often occurs accidentally on the interior of test-tubes when testing for silver by reagents, but looking-glasses are "silvered" with an amalgam of tin and quicksilver containing no silver at all.

Mercury or Quicksilver. Mercury or quicksilver (*Hydrargyrum*; symbol Hg; atomic weight 200) comes chiefly from the State of California. It is found also in other parts of the world in its metallic state, and in combination with sulphur as cinnabar. It is obtained from its ore by distillation, and is the only known metal which is liquid at ordinary temperatures. Brought into contact with other metals, it unites with them to form an amalgam, except in the case of iron and platinum, which are not attacked by it.

Mercurial Thermometers. Mercury is extensively used in the construction of thermometers because of its fluidity through a considerable range of temperature, and from its low specific heat, causing it to respond quickly to changes of temperature. It does not adhere to the glass, and hence in a large tube is always rounded on the upper surface, but it is so mobile that it will traverse a very minute tube, as in clinical thermometers, where the expansion of the mercury in the bulb produces a considerable travel, or large scale of movement, in the capillary tube.

Platinum. Platinum (symbol Pt; atomic weight 197) is a very valuable metal, only dating from 1741. It occurs in the metallic state, is very malleable and ductile, and resists the action of heat, oxygen, and acids. Although

very expensive, it is much used for crucibles and evaporating basins, but must not be heated in connection with metals, as it forms an alloy with them very readily. On account of its resistance to corrosion it is used for forming the touch-holes of small arms and cannon. In its finely divided state as spongy platinum it has the property of condensing gases into its pores, which raises its temperature to calorescence, and forms the basis of the self-lighting mechanism for incandescent gas mantles.

Arsenic. Although a metal, arsenic (symbol As; atomic weight 75) is not used in the metallic state. It occurs as an impurity in copper, tin, and zinc ores, and is very poisonous. It occurs in some green pigments, and from this cause old wall papers with green colourings were often very poisonous, but other green colouring matters have now been discovered by which its use is obviated. It renders wrought iron cold-short and hinders welding.

Bismuth. Bismuth (symbol Bi; atomic weight 210) occurs in ores with nickel, cobalt, copper, silver, and arsenic. It has a reddish colour and a highly crystalline appearance, is very brittle, and is only used in its pure state in the construction of thermo-electric piles, composed of alternate bars of bismuth and antimony, which are used as very delicate thermometers by the generation of electric currents. Its chief use is in the formation of fusible alloys.

Manganese. Manganese (symbol Mn; atomic weight 55) is not used alone. In cast iron, where it is always present to a small extent, it tends to produce the white variety. In wrought iron it renders the removal of phosphorus and sulphur more complete in the puddling process, although the puddling is attended with more difficulty. In steel, in small quantities, it increases the tenacity and causes it to weld more freely.

Metalloids. This is the name given to several chemical elements which, although not metals, have some of their characteristics. The following are the principal metalloids.

Carbon. Carbon (symbol C; atomic weight 12) occurs in several well-known but widely diffused forms—as the diamond, charcoal, graphite or blacklead, soot, lampblack, &c. In iron it produces fluidity and in steel hardness, while in copper it produces brittleness. When burnt with a limited supply of oxygen, it forms carbon monoxide, carbonic oxide, or fire-damp (CO), which burns in the presence of more oxygen to form carbon dioxide, carbonic acid, or choke-damp (CO_2). CO is poisonous, but CO_2, although not directly poisonous, will neither support combustion nor life.

Silicon. Silicon (symbol Si; atomic weight 28) occurs as an impurity in wrought iron, and reduces its tenacity more than phosphorus does, acting whether the iron is hot or cold. A small quantity of silicon in steel produces sounder ingots, but it should not exceed ·08 per cent. In combination with oxygen silica is produced, which is the substance of common sand and is largely present in all fire-clays.

Sulphur. Sulphur (symbol S; atomic weight 32) is the pale lemon-yellow crystalline substance, which enters into combination with very many metals to form sulphides and with oxygen to form sulphates. It is also well known in combination with oxygen as sulphur dioxide or sulphurous acid (SO_2), in combination with water as sulphuric acid (H_2SO_4), and in combination with hydrogen to form hydric sulphide, sulphurreted hydrogen, "or rotten egg gas" (SH_2). It is the action of sulphur in the air that tarnishes silver. In combination with iron or steel it causes them to be red-short, but in steel this is somewhat counteracted by the presence of manganese.

Phosphorus. Phosphorus (symbol P; atomic weight 31), in its pure state, is like a semi-transparent crystalline wax, which combines freely with oxygen. It is largely used in one or other of its forms in the manufacture of domestic matches. Its combination with wrought iron causes cold-shortness, or brittleness. In cast iron it increases the hardness and fluidity. In steel it causes brittleness; in copper it increases the tenacity and the fluidity, and renders castings sounder.

Fluorine. Fluorine (symbol F; atomic weight 19) is only of interest because of its intense action. When liberated in any chemical process it immediately attacks the containing vessel. In combination with hydrogen forming hydrofluoric acid (HF), it has the property of dissolving glass and other compounds of silica, and is therefore used for etching on glass.

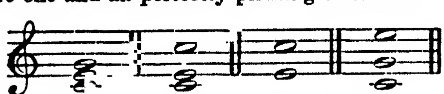
HARMONY: CHORD-MAKING AND MANAGEMENT

The Common Chord; Chord Progression; "Motion" of Parts; Consecutive Fifths and Octaves; Cadences and Sequences; Inversions of Chords

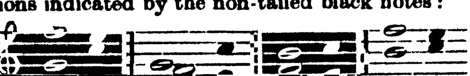
By J. CUTHBERT HADDEN

FOLLOWING the study of intervals comes very naturally an introduction to the study of harmony, since all harmony is founded on the combined use of intervals arranged according to certain laws. For the purpose of this study of harmony we have to distinguish two kinds of interval, consonant and dissonant. When two or more sounds heard together produce an agreeable sensation on the ear, the result is termed *concord*. In that case the intervals are consonant. When the sensation is not so agreeable—when *discord* is produced—the intervals are dissonant. Listening to the notes of a consonant interval or intervals struck together we feel the result to be complete and satisfactory in itself; whereas the dissonances, though not necessarily harsh and repugnant, are felt by the ear to be unsatisfactory and suggestive of other combined intervals to follow. This may be illustrated in a very simple way. Here, for instance, are four consonant combinations which are one and all perfectly pleasing to the ear:



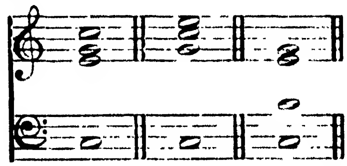
They can be played or sung, each by itself, without any acute desire for something to come after.

On the other hand, such combinations as are shown by the semibreves in the following illustration are altogether unrestful for the ear. They are made up of dissonances, and suggest, if they do not actually demand, the combinations indicated by the non-tailed black notes:

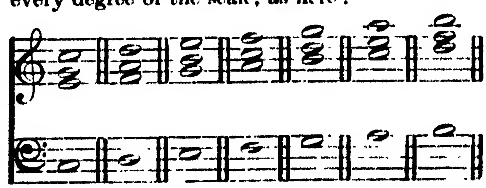


The harmony student, then, must know how to distinguish between the consonant intervals and the dissonant. That, happily, is not difficult. The consonant intervals are the unisons and octaves, the major and minor thirds, the perfect fourths and fifths, and the major and minor sixths; the dissonant intervals are the major and minor seconds, sevenths, and ninths, and all augmented and diminished intervals. A combination of three or more of these intervals is called a *chord*; a *concord* when consonant intervals are only used; a *discord* when dissonant intervals make a constituent part.

Concords and discords are naturally of many kinds, for the combinations which can be produced by the union of diatonic and chromatic intervals are very numerous. But the basis of all possible combinations is the triad or common chord. This consists of a fundamental note as bass, with its third and fifth added. Thus, if we sound the notes C, E, and G together, we have a triad or common chord—the common chord of C. Add the octave of the foundation note (C) and the chord admits of three principal positions:



It is plain that we can build up a chord on every other degree of the scale by the same process of adding a third and fifth above the foundation note. But here we have to mark certain important differences which arise in the structure of chords. Suppose we set down a triad on every degree of the scale, as here:

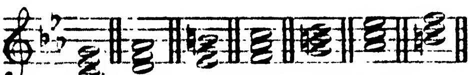


Now look at the lower thirds in these combinations. In the case of the chords on the first, fourth, and fifth degrees, these thirds are major, while those on the second, third, and sixth degrees have minor thirds. The difference is essential; for it divides the chords of the scale into two classes—major chords when the lower third is major; minor chords when it is minor. One chord, that on the seventh of the scale, stands by itself. All the other chords, while they disagree as to their thirds, agree in having a perfect fifth. This chord on the seventh degree is unique in having a minor third and an imperfect fifth, hence it is termed an *imperfect*, sometimes a *diminished, chord*.

Thus, then, of the seven chords of the major scale, three are major, three are minor, and one is imperfect. Naturally the most important of the lot are the three major chords, those upon the tonic, dominant, and subdominant. These are sometimes called the fundamentals of harmony, because by their use alone every note of the scale may be harmonised. Chords, let it be added, are named from their roots according to the degree of the scale that the root is founded upon—as tonic, supertonic, mediant, etc., etc. Thus we speak of the chord C, E, G as the chord of the tonic when the key is C, of E, G♯, B

similarly when the key is E; and so on. As a theorist has it, "it is to the relation of chords to a scale or key that attention must be directed." At the same time we can speak of chords without reference to the key-relationship: the chord of C, of G, of F, and C in whatever key these are found.

The chords of the minor scale demand some special consideration, chiefly on account of the artificially altered notes of that scale. In the major scale, as has been seen, the foundation chords are characteristically major. One would naturally expect that, conversely, the foundation chords of the minor should be minor. But this is not the case. Take an illustration in C minor:



Minor. Imperfect. Augmented. Minor. Major. Major. Imperfect.

Here only two chords, those of the tonic and the subdominant, are minor. The dominant is converted into a major chord by the incidental raising of the seventh note of the scale. The uses of these three chords in their root positions are exactly the same as in the major. The chords on the minor supertonic and on the leading note are imperfect and cannot be used in their root positions. On the raised sixth there can be no common chord, nor on the mediant when the seventh of the scale is raised, though we must recognise it as an augmented triad since it is occasionally used. It must be frankly allowed that the chordal usages of the minor scale present many perplexing problems to the young student. They arise chiefly, if not entirely, from the varied forms in which the minor scale is written and are therefore inevitable. Only as his practice extends, and his theoretical knowledge widens, can the student hope to thoroughly master this branch of his subject.

Thus, then, we have learnt about the constituents of common chords. Now we have to learn something of the way in which these chords are used. For, of course, chords cannot be made to follow each other at pleasure: the *progression* of every note in a succession of chords must be carefully considered. Hence we arrive at the elementary rules of part-writing. When we speak of "parts," we generally mean four voices (treble, alto, tenor, bass) or four instruments. That is the simplest and best method of studying the progression of chords.

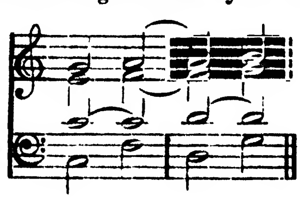
Well, first of all, since concords have but three constituents, we must see which constituent can be "doubled" for four-part writing. The rule is to double the root first. If the context does not allow of that being done, then double the fifth. The third, when it is major, must not be doubled except in special circumstances; nor must it be omitted whether it is major or minor. The third of a chord, remember, is what determines whether the chord is major or minor, and if it is omitted the chord has no definite character. Moreover, it is the third which gives a chord its harmonic life and quality. The fifth may be omitted without detriment; the third never.

This matter of "doubling" having been arranged, we have next to understand how the individual notes of the chord are to be disposed among the various parts. Clearly it would be impossible always to superimpose them in the order of root third and fifth; and indeed there is no restriction about the distribution of the notes of a chord beyond this, that the lower notes should be separated by the largest intervals, and that the diminution of the intervals should be gradual. Look at the following:

(*a*) (*b*) (*c*)

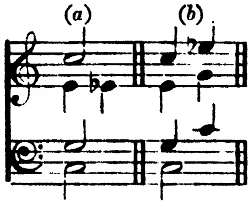
Here we have various arrangements of the chord of C. Those at *a* are perfectly satisfactory; those at *c* less so; those at *b* altogether bad. The essential thing to remember is that in distributing the constituents of a chord there should be no disproportionate hiatus: that the largest intervals should be at the bottom, the smallest at the top. Except in the case of bass and tenor, none of the parts should be separated by an interval exceeding an octave.

We speak next of the connection of the various chords. Here the rule is to choose as far as possible chords which may be connected by one or more notes common to both. Thus the chord of the tonic might be followed by that of the subdominant, because the note C is common to both, by that of the dominant because the G is common. The subdominant, again, might be followed by the supertonic chord because A is a constituent of both; and so on, as here, the common note being indicated by the tie:



Moreover, when two notes of the same name and pitch occur in consecutive chords it is well to keep them in the same part in both chords, as in the above example. This produces a smoothness and a tranquillity not to be obtained otherwise. It is, however, a recommendation rather than a rule, and applies more particularly to the inner parts (alto and tenor): the rule is practically absolute (there are one or two exceptions) when two notes of the same name but of *different pitch* occur in two consecutive chords. In this case the two notes *must* be in the same part, otherwise there is produced what is termed a *false relation*. Thus, if we have E in the alto part of a chord

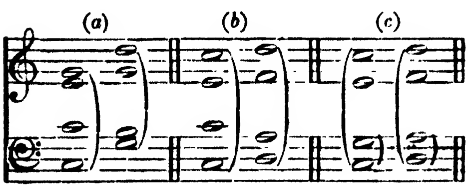
and write E flat in the soprano part of the next chord, the result is a false relation. See the following example, where (*a*) is according to rule and (*b*) is not:



Note that the bad effect of a false relation often remains though a chord intervenes between the chromatic notes.

So much for connecting pairs of chords. Now to consider the general *motion* of the parts. "Motion" is a technical term, representing three separate kinds of movement. We have *similar motion* when two or more parts ascend or descend at the same time; *contrary motion* when one part ascends while the other descends; and *oblique motion* when one part remains stationary while the other ascends or descends. Of the three, contrary motion is preferable, not only because it is most grateful to the ear, but because it is less likely to lead to infractions of the rule as to consecutive fifths and octaves, of which we shall speak presently. Similar motion in all the parts should be avoided if only because of the tame effect produced. A mixture of two or of all three forms of movement will generally give the best result.

Closely connected with this matter of motion is the important rule—one of the most important in part-writing—which forbids two or more perfect fifths, octaves, or unisons between the same two parts, whether by skip or conjunct movement. Here



at *a* we have consecutive fifths between bass and treble; at *b* consecutive octaves between the same parts; at *c* both consecutive fifths and octaves, the first between bass and tenor, the second between bass and treble. In similar motion the effect of such consecutives is especially bad; in contrary motion they are rather less objectionable. To make the parts move in an opposite direction to the bass is one of the surest methods of avoiding them. Of course the student will understand that the forbidden intervals apply only to an actual progression of simultaneous parts. Where there is no melodic movement there is no objection to a repetition of fifths or octaves between any two parts. Thus the following are not regarded as infringing the rule:

Note also that consecutive fifths are not forbidden when one of the fifths is imperfect.

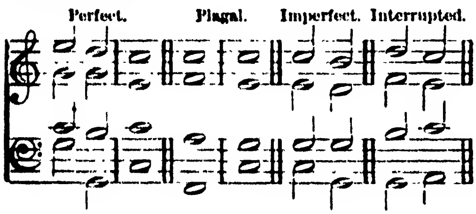
What are called *hidden consecutives* must also be avoided. These are much less easily discovered by the unpractised harmonist, being always, as their name implies, hidden or covered over. The rule is that the extreme parts (treble and bass) are not to proceed by similar motion to an octave, fifth, or unison. Thus, if we write
C, E.
A, E. we are said to produce a "hidden" consecutive octave, because, were the scale notes between in both cases filled in, we should have D going to E in both parts. Similarly we have here a "hidden" fifth

as shown by the filling in with the small-sized crotchets. There are several exceptions to the rule about hidden consecutives, but in all his early work the student is advised to observe rigidly the other rule to which it gives rise, namely, that in the outside parts a perfect concord or unison should be approached by contrary or oblique motion. In regard to all these rules of part-writing it must often be a case of one rule yielding to another—laws of progression to laws of position and *vice versa.* Violations of most rules will be found in the works of the great masters, the good effect produced being sufficient justification. Before the young harmonist thinks of following their example, he should see that his theoretical knowledge is complete. In any case, the rules against consecutive fifths and octaves admit of practically no infringement.

Let us look now at the various kinds of *cadence.* A cadence, in the ordinary use of the term, is the close of a musical sentence. Generally the two last chords determine its character as *perfect* or *imperfect, plagal* or *interrupted.* The perfect cadence, as its name suggests, is the most satisfying, and on that account is used at the end of every composition and generally at the end of every movement. It consists of the major chord of the dominant (a seventh may be added), followed by the tonic chord. The imperfect cadence, in its commonest form, exactly reverses this order of chords: the tonic chord

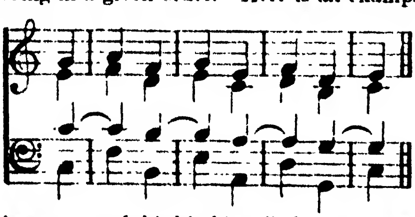
comes first and is followed by the dominant. This cadence is of course never used at the end of a composition, but only at the end of a phrase or section. It "seems almost to ask a question."

In the plagal cadence the determining chords are the sub-dominant and tonic. This cadence is most frequently met with in sacred music, as at the close of Handel's Hallelujah Chorus. The interrupted cadence is something of a contradiction, being "in the strictest sense, not a cadence at all, but the interruption of one by the appearance of some other than the tonic chord, when the progression has been such as to lead to the expectation of a perfect cadence." Interrupted cadences are harmonically of various kinds. The most usual form arises from the progression of the dominant to the sub-mediant chord. All these forms of cadence are simply illustrated here:

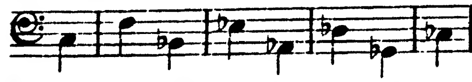


In choosing his cadences the student should aim at securing variety. This is the more necessary in a short composition, where repeated use of the same form of cadence would produce a very monotonous effect.

The subject of *sequences* need not detain us, for the sequence, though frequently beautiful in effect, is of the nature of a mechanical device. It may be defined shortly as a repetition of the same succession of intervals on different degrees of the scale. Thus the melody may alternately rise a second and fall a third, the bass rise a fourth and fall a fifth, the other parts also progressing in a given order. Here is an example:



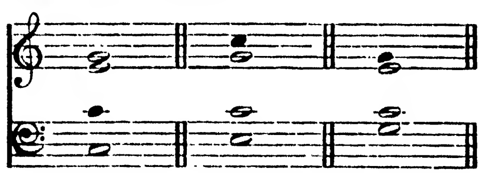
A sequence of this kind is called tonal, because the intervals all belong to the unaltered scale. They are minor or major, perfect or imperfect, just as they present themselves. In the *real* sequence, so called, the respective intervals are exactly alike. Thus, in a real sequence, the above bass part would have to be written thus:



so that every rising fourth and falling fifth should be perfect according to the pattern.

Tonal sequences are much more frequently used than real. When the bass or melody moves sequentially the other parts should do the same, though, for variety's sake, this rule may sometimes be ignored. Sequences are held to justify the infringement of a good many laws of part-writing, the ear being attracted and pleased by the evident *design* of the pattern, and so likely to accept what in an ordinary progression might sound objectionable. Thus a sequence provides almost the only exception to the rule against doubling the leading note.

Up to this point we have dealt with chords solely in their original positions—that is, having the foundation note in the bass. When this note is not in the bass—when it is transferred to an upper part—the chord is said to be *inverted*. A common chord consists, as we know, of three constituents: hence such a chord is capable of two inversions. When the third is put in the lowest part, the chord is in the first inversion; when the fifth, it is in the second inversion. Thus, in the triad of C, we have these three positions, the black note being the doubled note necessary in four parts:



Original Position. First Inversion. Second Inversion.

Note, in passing, that the root of a chord and the bass note are not necessarily the same. In the above illustration the root in all three cases is C; and from this example the student will gather at once that in first inversions the root is a third below the bass note, while in second inversions it is a fifth.

VARIOUS METHODS OF SURVEYING

Including Traversing, Plotting and Levelling, and dealing with the Beam Compass, Planimeter, Pentagraph, Eidograph, Level and Level Staff

By Professor HENRY ROBINSON

Traversing. In our study it has been assumed that the lines of the survey have been tied in by means of chain angles, or that only the main lines have had to be fixed by angular measurement. A common way of carrying out a survey is by *traversing*. For the purposes of this course it is assumed that the earth is a plane surface, and that no corrections for its spherical form are necessary. This assumption for all practical purposes, where the areas surveyed are limited, will cause no appreciable error.

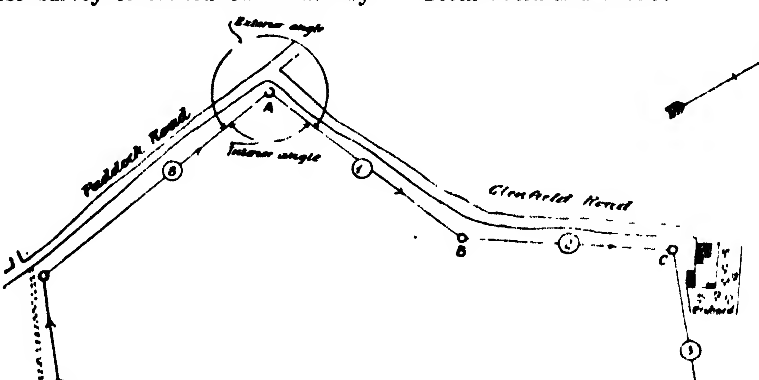
A traverse survey is carried out either by taking the "bearings" of the lines, or the angles between the lines, or by taking both with a theodolite, or some other instrument. The lengths of the lines are measured as in an ordinary chain survey. When practicable the traverse should be "closed," that is, the end of the last line of the traverse should finish at the commencement of the first line, a practice which forms a check on the work. If it be impossible to close the traverse, a series of observations should be taken from the various stations to some well-defined point, preferably within the survey, to form a check. When a traverse is carried out by taking the bearings of the lines only, and not by taking angles, the bearings should be read both forward and backward, to eliminate any chance of error.

As greater accuracy can be attained by reading the angles either external or internal, this method is preferable. One bearing accurately obtained is, however, essential in order to fix the relation of the various lines to the magnetic north. The bearings of the other lines can be calculated after reading the angles between them, as will be explained later. We know from Euclid (Book 1, Prop. 32, Corollary) that in any closed polygon the following obtains:

1. The sum of the interior angles plus four right angles is equal to twice as many right angles as the figure has sides.

From which is deduced:

2. The sum of the exterior angles minus four right angles is equal to twice as many right angles as the figure has sides. From this it will be seen that if the angles (either exterior or interior) of a closed traverse are read, they may be checked by calculation.



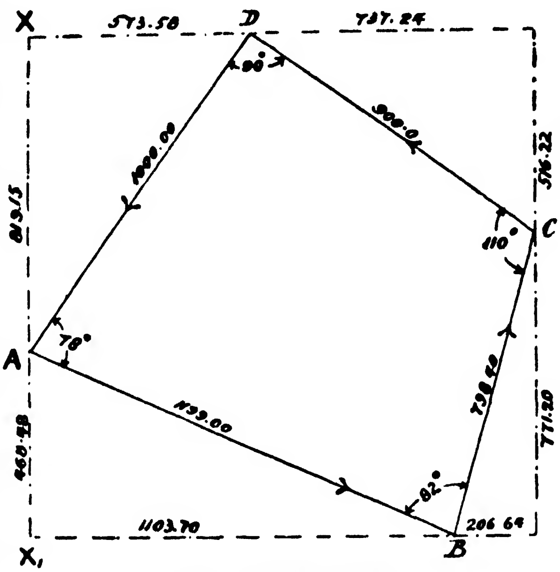
21. TRAVERSE SURVEY

When it is intended to carry out a traverse, it is necessary to adopt some system of reading the angles to avoid errors due to first taking an internal angle, and at another time an external angle, as, although they may have been properly noted, it would be necessary to employ some calculation in order to see whether the traverse was correctly carried out by the calculation of the sum of the angles as previously explained. A good method is always to set the instrument on the backward station first, and then to read on to the forward station (from left to right). If this is done, the rule that is given later for

calculating the bearings of lines from the angles between them will always obtain. The illustration [21] shows a survey carried out by traversing.

A Survey by Traversing. The figure is shown as "closed," although it frequently happens that on starting a traverse the closing line will not be set out until nearing the completion of the work. The method of making this survey was as follows. Ranging poles were set up at the most convenient places, as shown on the illustration by the small circles at the points where the lines join each other. The instrument was then set up at the beginning (A) of line 1, and the forward bearing of AB taken (as explained when dealing with the theodolite), and the exterior angle read. The instrument was then removed and the line chained, the offsets being taken in the usual manner.

This having been completed, the instrument was set up at B, the end of the line, and the backward bearing (BA) of line 1 was obtained. Line 2 was then set out, and a pole put up at C, when the exterior angle ABC was read. This proceeding was continued until the survey had been completed. The direction in which the lines were chained is indicated on the illustration by arrow heads.



22. TRAVERSE SURVEY

Method by the Bearings alone. As previously explained, this survey could have been completed by means of the bearings alone. The method adopted must depend on the degree of accuracy required.

If the accurate bearing of one line is known, the bearings of all the other lines can be calculated by the following rule, provided that the instrument is first sighted on the back station in reading the angles between the lines. The result of this is to give the external, or internal, angles according to the direction in which the chaining takes place. The bearing will, of course, vary by 180°, depending upon whether it is read backwards or forwards. In any case, the bearing is taken in the same direction as the chainage.

The bearing of any line may be calculated with regard to the bearing of any other line, the angle between them (whether external or internal) being known, in the following way: To the known bearing, add the angle between the side to which it refers; and to the next side, if the sum be less than 180°, add 180° to it; the result is the bearing of the line required. If the sum be more than 180°, deduct 180° from it, and if the remainder be still more than 360° deduct 360° from it; the result is the bearing of

Stations	Distances	Inward Angles	Theodolite Bearings	Reduced Bearings	Single Traverse				Total Traverse	
					N	S	E	W		
1	2	3	4	5	6	7	8	9	10	11

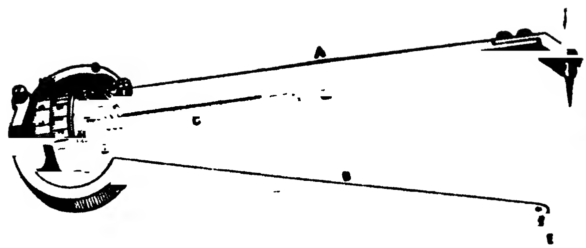
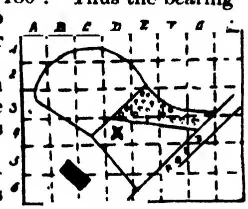
23. REDUCTION BOOK



25. PLANIMETER

the line required. As an example, we may assume the theodolite set up at A [22], and the direction of chaining to be from A towards B. The bearing of the first line AB is taken and its length chained. The interior angle between it and the last line DA is taken. The theodolite is transferred to B, and the angle ABC is observed. The bearing of BC is obtained as follows:

Bearing $AB = 113° 0'$. Angle $ABC = 82° 0'$. Their sum $= 195° 0'$. Then, as already explained, $195° 0' - 180° 0' = 15° 0'$, which is the bearing of BC. As another example, supposing that the traverse was chained the reverse way, the angles read would be exterior angles, and the bearings would differ by 180°. Thus the bearing CB would $= 195° 0'$. To this add the exterior angle $CBA = 360° - 82° = 278°$. The sum would, therefore, be $195° + 278° = 473°$. As before, $473° - 180° = 293°$, which is the bearing of BA, and equals $113° + 180° = 293°$. By the above method the angles all round the survey are observed, and the lengths of the lines chained. It now remains to be shown how these are to be plotted.

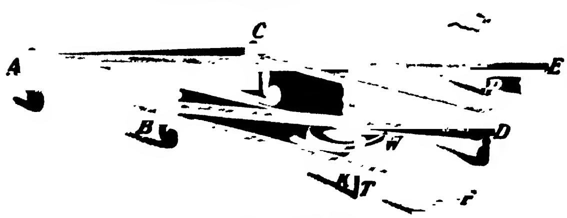


PLAN A

"Northings and Southings" Method. A common method for plotting is by the Protractor. A more accurate way is by means of what is known as *Northings and Southings*, or *Latitude and Departure*. By this method, as will be shown later, the field book is worked out first, and any errors detected before the plotting commences. We know, from trigonometry, that in any right-angled triangle

$$\text{Sine} = \frac{\text{Perpendicular}}{\text{Hypothenuse}}$$

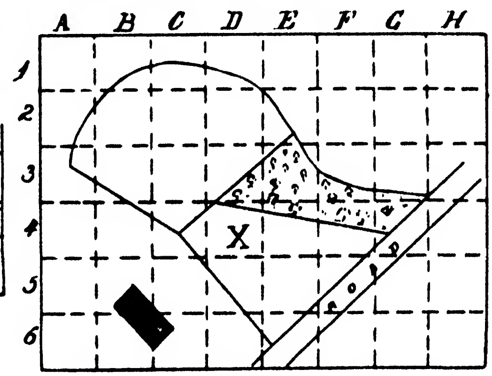
$$\text{Cosine} = \frac{\text{Base}}{\text{Hypothenuse}}$$



26. PENTAGRAPH

Referring again to **22**, if there be any line, AB, of known length, making an angle $X_1 AB$ with any line XX_1, it is possible to calculate the distances AX_1 and X_1B so that by scaling off AX_1 and drawing a perpendicular X_1B to XX_1, and making it equal to the calculated length, the position of B may be fixed by scaling alone. Thus $\frac{X_1A}{AB} = \cos X_1AB$, and therefore $X_1A = AB \cos X_1AB$. Similarly $X_1B = AB \sin X_1AB$. In a traverse survey the bearings (calculated or observed) are the positions of the lines with regard to the North, and may be anything up to 360°.

For the purposes of plotting, it is required to get the actual angle made with a line running North and South (X_1X). This is termed the *Reduced Bearing*, and is used to calculate the distances for fixing the lines on the survey. "Reduced Bearings" may be calculated from the *actual* bearings as follows:



PLAN B

24. ENLARGEMENT OF PLANS

For bearings less than 90° take the bearing direct; for bearings greater than 90° and less than 180°, take 180° − the bearing; for bearings greater than 180° and less than 270°, take bearing − 180°; for bearings greater than 270°, and less than 360°, take 360° − the bearing.

From the above rule it will be found that our reduced bearings are always less than 90°, and therefore the sines and cosines can be obtained from an ordinary set of mathematical tables.

Plotting. In plotting the work, first draw the line XX_1 being the North and South, or *meridian* line. Upon this line a point A is fixed, being the commencement of the survey, and is called the *origin* point. The distances from point to point measured along, or parallel to, this line XX_1 are called the differences of "*latitude*," or *northings* and *southings*, according to their direction. The distances perpendicular to the line are called the *departure*, or

eastings and westings, according to their direction. These directions are obtained from the actual bearings, and are as follows:

0° to 90° = N. and E.
90° to 180° = S. and E.
180° to 270° = S. and W.
270° to 360° = N. and W.

Figure 23 is an example of the *Reduction Book* completed for this case. Referring to this in conjunction with 22, an illustration will be given to show how this book is made up. The bearing of AB is 113° 0′, which is S. and E. The "reduced bearing" is therefore 180° − 113° = 67°, and is entered in column 5, with its sign S.E. The length of AB is 1199, and 1199 cos 67° = 468·48, and 1199 sin 67° = 1103·70. These distances are entered in columns 7 and 8, plotted as shown, and the point B fixed. The next bearing is 15° and, as explained, this bearing, being less than 90°, is the reduced bearing, and is N. and E. The distances are calculated as before (the measured distance of BC being 798·4). As this direction is N. and the previous one was S., the difference of the amounts must be obtained in order to get the actual distance from the origin, and is entered in column 10 (302·72 N.).

The departure is a still further easting, and must be added to the previous reading to get the total distance, and is entered in column 11 (1310·34). The last two columns of the reduction book enable the errors to be observed. If the angles check by calculation, the total error, if any, is in the chaining. The distances are shown on 22, as are the total distances from point to point.

After the fieldwork for a survey has been completed, the work has to be plotted. The scale for plotting must depend on the purpose of the survey. A convenient scale for small surveys is one chain to the inch, but this is too large for extensive surveys. The three scales of the Ordnance Survey are $\frac{1}{2500}$ (or what is termed the 25-inch ordnance), the 6 in. and the 1 in. being 6 in. and 1 in. to the mile respectively.

The Beam Compass. The first thing that has to be done is to plot the survey lines. If of any length this is done with the aid of the *Beam Compass*, by means of which arcs of circles are struck representing the lengths of the various lines from their respective points, and the intersections of these arcs give the points to which the lines have to be ruled. When these survey lines are all plotted and checked, the offsets from the various points of the lines have to be drawn at right angles to the lines. This is best done by means of an *offset scale*, which is a small portion of the main scale (usually 12 in. long). The 12 in. main scale is laid along the line, and the smaller offset scale is moved along it (of course, at right angles), and the various points are pricked off and afterwards joined up. It is often necessary to take out areas when the survey has been plotted. The most convenient method is by means of a "Planimeter," one form of which is as follows:

Amsler's Planimeter. This Planimeter [25], when ready for use, as in the diagram, rests upon three points, D, E, F. These are respectively: first a point of the circumference of the divided wheel D; secondly, a point of the tracer F at the end of the arm A; thirdly, a point E at the end of the other arm B, which is kept fixed during the time of operation.

Place the point E at a convenient distance from the figure to be measured, so that the tracer F may traverse the entire periphery of the figure; but if the figure is too large to allow this, it can be subdivided by drawing straight lines through it, and the contents of the several parts computed separately and added together. Then place the point of the tracer on any convenient starting-point in the periphery. When the instrument is thus adjusted, read off the division on the horizontal disc C, also that on the perpendicular wheel and vernier, H. Suppose that the horizontal disc gives 3, and the vertical wheel gives 905, namely 90 on the wheel and 5 on the vernier, this reading must be put down thus, 3·905. Then carry the tracing point round the figure in the direction of the hands of a watch; and when the whole circuit has been made, observe the reading again. Suppose them 5·763, then subtract the former reading from the latter, the result will be 1·858; multiply this by 10, and you get the contents of the figure in square inches, namely 18·58. Notice must be taken whether the disc C has made an entire circuit, if so, 10 must be added for every revolution to the whole number. Thus, if the disc had gone once round, the second reading would have been 15·763; if twice round, 25·763, and so on.

Scaling an Area. In the event of it being necessary to take out the area by scaling alone, the plot must first be divided up into convenient forms, as for instance, into triangles. In the case of a field surrounded by irregular or curved fences, it will first be necessary to reduce them to straight lines. This can be done by the eye on the "give and take" principle. The area of a triangle is found by multiplying the base by half the perpendicular line drawn from the base to the apex of the triangle. If the three sides of a triangle are known, the following formula will give the area:

$$\text{Area} = \sqrt{s \times (s-a) \times (s-b) \times (s-c)}$$

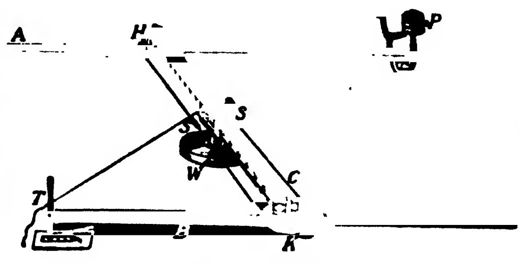
where $s = \frac{a+b+c}{2}$; a, b, and c being the length of the respective sides.

Reduction and Enlargement by Squares. Plans may be enlarged or reduced by means of squares. The method is simple and accurate if carefully carried out. The plan (A) to be enlarged [24] is divided into squares of suitable size. Having decided on the size of the enlargement (B), divide a clean sheet of paper into squares, the size of which must be according to the scale of the enlargement. Then each square on the plan (A) will be represented by a larger square on the clean paper.

The figures, lines, etc., contained by the squares on plan A must be carefully measured

and reproduced in their respective squares on plan *B*. Each square can be numbered as shown on the figure, the cross on the square *D*4 being an example. For reducing plans rapidly the *Pentagraph* and *Eidograph* are used.

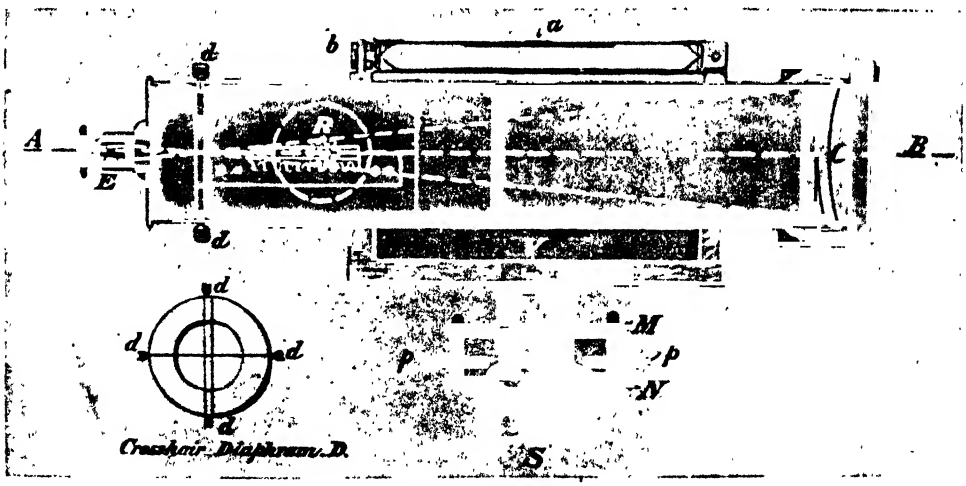
The Pentagraph. This instrument [26] is made from 12 in. to 4 ft. in length, and consists of four bars, two long and two short. The long bars, *AE* and *AF*, are jointed at the point *A*. The short bars, *BD* and *CD*, are jointed at the point *D*, the other ends being attached to the long bars at the points *B* and *C*. This arrangement of jointing produces parallel motion in the instrument. The whole instrument pivots round a weighted centre (*W*) (which is the fulcrum), the bars being supported at intervals by ivory wheels to allow free motion when at work. The pencil, tracer *P*, and the weighted centre *W*, are attached to the bars by tubes which the bar *BD*, the pencil on the bar *AF*, the tracer on the bar *AE*. If it be required to reduce a plan to one-third of its size, place the slide on each divided bar to the division marked ⅓, the pencil being on the bar *BD*, the fulcrum on the bar *AF*, and the tracer on the bar *AE*.



27. EIDOGRAPH

Enlargements should be made by the method of squares, but may be made with the pentagraph, by interchanging the pencil and tracer. As any error is magnified according to the scale to which the enlargement is being made, it is not usual to employ the pentagraph where accuracy is required. The pencil can be raised or lowered as desired, by means of a silk cord provided for the purpose.

The Eidograph. This instrument [27] is used for a purpose similar to that of the pentagraph, but its construction is different. It consists of three bars or arms, *A*, *B*, and *C*,



28. THE LEVEL

enable them to be interchanged, as will be explained later.

The bars *AF* and *BD* are marked off into a number of divisions, and are provided with slides which can be moved to any required division on their respective bars, and are held in position by the clamps *K*. As a general rule, the following instructions should be observed.

On the graduated bars which carry the slides proportioned to the fulcrum and pencil there are usually 21 divisions. Those numbered ½, ⅓, to $\frac{1}{12}$ are to be used with the fulcrum on the bar *AF*, the tracer on the bar *AE*, and the pencil on the bar *BD*. The other fractions, ⅔, ¾, ⅘, and on to $\frac{11}{12}$, are used with the fulcrum on

working on a pivot or fulcrum, *W*. The centre bar *C* has a grooved pulley at each end (*H* and *K*) round which a steel band passes. Any movement of one pulley is transmitted by the band to the other pulley, thus producing the parallel motion. To these pulleys are attached square tubes through which the bars *A* and *B* are passed, clamps being provided to hold them in their required positions. All the bars are graduated, and have verniers to enable the arms of the instrument to be set to their proper positions.

To set the instrument for the reduction of a plan to any required proportion, take the sum and the difference of the fractional terms; then

as the sum is to the difference, so is 100 to the number which is required, and to which the arms and centre bar must be set. For example, to reduce a plan one-third—

$$3 + 1 = 4;\quad 3 - 1 = 2.$$

Then as $4 : 2 :: 100 : x$ (number required)

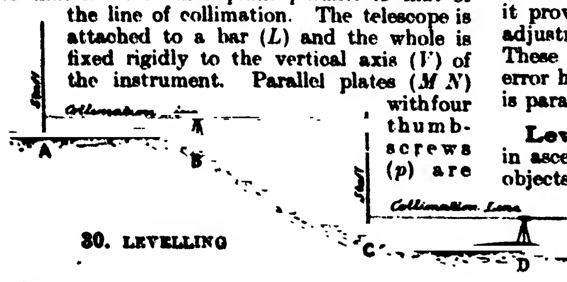
$$\therefore\ x = 50.$$

Then the arm carrying the tracer is lengthened and set to its division, 50. The centre bar is set at its division 50 (on the pencil side of its zero), and the pencil arm is shortened and set to its 50 division. For enlarging a plan the pencil and tracer must be reversed, but as with the pentagraph, all errors are magnified, and the instrument should not be used for enlargement.

The only adjustment which may be put out is the parallelism of the arms *A* and *B*. This is corrected by placing all the verniers to zero, and the arms at right angles to the centre bar *C*. Make a mark with the tracer and the pencil points, turn the instrument half round. The tracer point should fall into the mark of the pencil, and the pencil point into the tracer mark. Should this not occur, adjust by means of the screws (*S*) on the steel band until coincidence takes place.

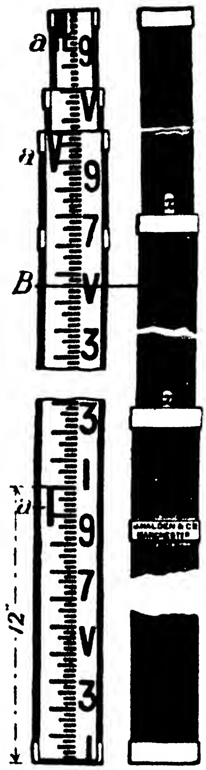
The Level. There are two forms of levels used in ordinary practice, being the "Y" and the *Dumpy*. With the former the telescope is supported in "Y's" (from which it can be removed and reversed in position), fitted to either end of a straight bar, one end being hinged and the other provided with a screw with nuts, by means of which the position of the telescope can be adjusted with reference to the vertical axis.

The *Dumpy* is similar to the "Y" level, but the bar and supports are rigidly fixed to the vertical axis. The illustration [28] shows a dumpy level. The body of the telescope is constructed of a pair of tubes (fitting truly cylindrical and straight) that slide in and out freely, being operated by a rack and pinion (*R*) enabling the image obtained by the objective (*O*) to be focussed by the eyepiece (*E*). The telescope is fitted with a diaphragm (*D*) carrying crosshairs capable of adjustment by the screws (*d*) provided for the purpose. This enables the plane of the horizontal crosshair to be brought to coincide with the plane of the line of collimation (*AB*), which is the central horizontal axis of the telescope. A spirit level is attached to the top of the telescope and a screw (*b*) with locknuts is provided to enable the bubble to be adjusted so that it works in a plane parallel to that of the line of collimation. The telescope is attached to a bar (*L*) and the whole is fixed rigidly to the vertical axis (*V*) of the instrument. Parallel plates (*M N*) with four thumb-screws (*p*) are provided to enable the instrument to be set level. The whole instrument is attached by a screw socket (*S*) to a tripod.



30. LEVELLING

To prepare the instrument for working, first set it firmly on the ground, approximately levelling it with the eye, and the lower of the parallel plates, then turn the telescope over two of the screws (*p*) and simultaneously turn them inwards or outwards, according to the travel of the bubble. By this operation the bubble is brought to a central position in its tube. Then turn the telescope over the other two screws, manipulating them as already explained until the bubble is again central. These operations must be repeated until the bubble remains central whatever the position of the telescope.



29. LEVEL STAFF

Adjustments. The adjustment for the bubble of the spirit level is made by altering the locknuts and screws(*b*). Should the bubble be out of centre, tighten or loosen the screw till the error has been reduced by half, re-level the instrument by the parallel screws (*p*) as previously explained. Should any error still remain, repeat the operations until the bubble is central.

Next adjust the line of collimation so that it is parallel with the plane of the bubble. This adjustment may be effected by means of the collimation screws (*d*). These raise or lower the diaphragm *D*, which carries the crosshairs.

Set the instrument up on fairly level ground, midway between two pegs about three chains apart. Take readings on a staff placed first at one peg, and then at the other. These readings give the difference of level of the two pegs. Next set the instrument up nearer one staff than the other, and again take readings. Should any error be found between the readings, taken when the level was midway between the points, and when it was closer to one than the other, it proves that the line of collimation requires adjustment by raising or lowering the diaphragm. These operations must be continued until the error has been eliminated, then the line of sight is parallel to the axis of the bubble.

Levelling. The art of levelling consists in ascertaining the differences in the heights of objects. In this country the Ordnance Survey Department has determined the level of points all over the country, which are called *Bench Marks* (O.B.M.). Their positions are shown on the Survey maps

and on the spot by a symbol in the form of an arrow. Their values are given in terms of the approximate mean tide level at Liverpool, which is taken as the datum line. The heights of the various points on the ground are determined by taking readings with the level on to a graduated staff, which we will now describe.

The Level Staff. The level staff [29] is generally made 14 feet long, being divided into three parts which telescope into each other. When closed up the staff is about five feet long. To prevent inaccurate records being taken by the staff not being properly extended, spring catches (x) are fixed to the joints of the staff. These catches, when locked, prevent any further movement. The staff is divided up into feet and $\frac{1}{100}$ of a foot. The left-hand figures lettered (a) are in red and represent feet, the right-hand figures are black and represent $\frac{1}{10}$ foot or 0·10, the smallest subdivisions being $\frac{1}{100}$ foot, or 0·01. Taking an example: The crosshair of the level cuts the staff at BB, so that the reading is 4·45, as the red figure five (for feet) is above this point, and the black five (for tenths) is just above it. The staff holder has to be careful in his work. The staff must be held quite vertical, and to do this on sidelong ground a plumb bob is sometimes used. If the staff be held out of truth laterally, it can be detected by the vertical wires in the level. To ensure the staff being held vertically, a simple plan is to move the staff slowly backwards and forwards, and the lowest reading that is got by the intersection of the horizontal wire of the level will be the correct one to book.

31. LEVEL FIELD BOOK [REDUCED]—"RISE AND FALL" METHOD

In choosing the place in which to hold the staff a firm spot is taken, and it is well to have a small piece of slate to place on the ground, for the staff to rest on and prevent its sinking into the ground. It also fixes the point where one reading has been taken, and ensures the staff being held at the same spot for the next reading. The purpose of levelling may be to obtain the level of one point with reference to that of another without any direct measurement to connect the two. This is frequently the case when it is desired to check points already set out, and it is termed *flying levels*. The route taken to obtain these should be one that involves the least amount of levelling between the points. In all levelling operations it is essential that the work should be checked, either by finishing up on a bench mark whose level is known, or else by returning to the starting-point, when the last reading, when reduced, should give the same level as that entered in the field book at starting. On the other hand, if it be necessary to plot an accurate section of the ground, it becomes necessary to chain between the points, and to take the various levels of points on the chain line as the measuring proceeds.

The Operation of Levelling. In commencing operations the level is set up at some convenient place where may be obtained a good view of the first point, which will be a bench mark, whose level is known. The position selected must also give a good view of the direction in which it is intended to proceed. The level having been set up, the staff is held on the bench mark, and the position where the horizontal wire cuts the staff is noted, and the reading booked in the *Back Sight* column. The staff is then moved forward, and held in the new position, and the reading taken, and entered up in the *Fore Sight* column.

The difference of these two readings will give the difference in the level of the bench mark and that of the ground where the staff was held in its new position. The level must now be shifted (the staff, however, remaining) and set up in its next position; a reading to the staff is then taken and entered as a back sight. The

reason for this will be apparent on referring to the illustration [30].

The level having been set up at *B*, a reading is taken on the staff at *A*, the ground level at which point is known, and this is a *back sight*. The staff is then shifted to *C*, and a reading at this point is taken, this being a *fore sight*. The difference of these two readings fixes the level of *C* with regard to *A*. If then the level be moved to another point *D* (the staff remaining at *C*) a reading can be taken to *C* (which is now known), and the staff can then be moved, the position of the level being now fixed with regard to *C*, and another position of the staff can be arranged.

Intermediate Readings. In the event of the levelling being required for some particular line of route (as, for instance, for the centre line of a railway), to enable the section of the ground to be plotted, it will probably be necessary to take a number of readings with the level set up in one position. Then, as before, the first reading at starting, taken after the level has been set up in a new position, is entered as a back sight, and any *intermediate* readings, with the level in the same position, are entered in the column provided for that purpose in the field book.

Rise and Fall. Figure 31 is a page of a level field book kept on what is known as the *Rise and Fall* method. Referring to this example, it will be seen that the first reading 9·30 is a back sight; the staff was then held at the beginning of the section line, and an intermediate reading taken of 11·60. As this reading is greater than the first one, it is obvious that the ground must have been lower, so the difference of these two readings is entered up in the *fall* column, and is subtracted from the reduced level of the first point, giving a reduced level of the ground at the new point of 153·68.

It must be remembered that when the following reading is greater than the previous one, it is a *fall;* the difference must be entered in the column provided for that purpose, and subtracted from the previous reduced level. When the following reading is less than the previous one, it is a *rise*. The difference must be entered in the *rise* column, and the amount added to the previous reduced level.

In order to check the page, to see that no errors have been made, the difference of the sums of the back sights and of the fore sights must equal the difference of the sums of the rises and falls, and these two differences must equal the differences of the reduced levels at the commencement and the end of the page. On reference to the example it will be seen that these amounts equal 48·74. Another way of keeping the field book is that known as the *Collimation* method, or H.P.C. (Highest Plane of Collimation).

The Collimation Method. A book kept in this way is shown in 32. The back sight is added to the reduced level of the first point. This gives the reduced level of the collimation line of the telescope. All other readings are subtracted from this, until the level is shifted, and another back sight is taken; this is added to the reduced level of the point at which it is taken, and all other readings are subtracted as before. This method of keeping the book is more rapid than the "Rise and Fall" method, because, to keep the book checked in the field, it is necessary only to deal with the back sights and fore sights, the intermediates being ignored, unless they are necessary for establishing any particular point.

Care, however, must be taken in reducing the intermediate levels, as there is no check on them for arithmetical errors. If at the end of a page of levels the last reading is an intermediate, it must be entered as a fore sight, and on turning the page, the same reading entered as a back sight on the top of the new page. The distance column is the same in both methods, and is used for putting in the various chainages. When it is necessary to take cross sections on lines at right angles to the main section line, poles are ranged out at right angles to the left and right of the line. These are

Curvature. In the preceding notes it has been assumed that the surface of the earth is horizontal, and that the readings on the staff obtained by the bisection of the collimation line of the level are the true ones. This is practically so for ordinary purposes. Where, however, extremely accurate work has to be done, and where long readings have to be taken, some correction is necessary to allow for the curved surface of the earth.

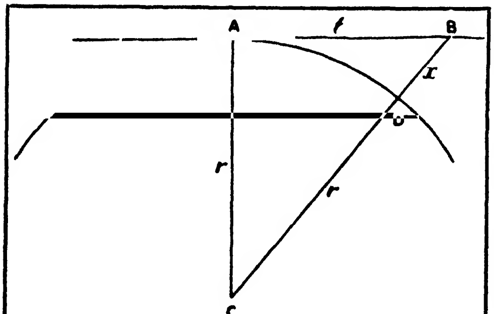
83. LEVEL FIELD BOOK—CROSS SECTION



$BD = x$ = ERROR DUE TO CURVATURE

$AC = DC = r$ = RADIUS OF EARTH

AB TAKEN $= AD = l$

$AC^2 + AB^2 = BC^2$

I.E. $r^2 + l^2 = (r+x)^2$

$= r^2 + 2rx + x^2$

$\therefore\ l^2 = x(2r+x)$

DISREGARDING x IN $2r+x$

$l^2 = 2rx \qquad \therefore\ x = \dfrac{l^2}{2r}$

MEAN DIAMETER OF EARTH = 7916 MILES

84. CURVATURE

The true figure of the earth is spheroidal, but for the purpose of correction for curvature it is assumed to be a sphere, the mean diameter of which is approximately 7916 miles.

Refraction. This correction for curvature is partly neutralised by what is known as "Refraction," due to the atmosphere. No absolute value can be laid down for this, as it must vary according to climatic conditions. A good practical rule is to take it equal to one-sixth that due to curvature. In any case, the error due to curvature and refraction is eliminated if the distances of the back sights and fore sights from the level are made *equal*. At distances not exceeding 10 chains the error is so small as to be negligible.

Care must also be taken to ensure the staff being held vertical and on firm ground. This caution applies also to the position chosen for setting up the instrument. Great care must be taken in reading the staff, as individual errors can only be determined by independent checking.

When the reduced levels of bench marks are being used, too much reliance must not be placed on the accuracy of the value given them, and independent levels should be taken between them to confirm their values. It is also useful in all operations to make temporary bench marks, by reading on to some well-defined points at intervals on the route, thus preventing the necessity of going back to the original starting point in case of errors.

To be continued

THE ROOM FOR BRAINS IN INDUSTRY

Some Openings for Men with Ideas. Simple Problems which the Inventive may Solve. Channels by which Old Enterprises may Develop and New Ones Arise

By ERNEST A. BRYANT

HAVING considered some of the achievements of men of ideas, it may be profitable to glance at a few of the more obvious avenues of progress for the benefit of the inventor and the community at large. We shall consider larger schemes in their place; here we shall merely direct attention to some of the minutiæ of our daily wants.

Sparks from Steam-engines. We must all bow to the dictum of the philosophers who tell us that we cannot summon an idea to birth. But the history of mechanical invention teaches us that demand is not uncommonly followed by the production of the thing desired. The Nasmyth hammer, like the many ingenious appliances with which Sir John Aird built his great bridges, came into existence to meet the urgent need of the hour. There must be many Nasmyths, many Airds, in the world to-day. Certainly there remains abundant scope for the exercise of their genius.

Does it not seem incredible that man, who can take the raw iron out of the earth and fashion it into a mighty engine capable of drawing hundreds of tons at the rate of sixty miles and upwards per hour, cannot devise the contrivance necessary to arrest and extinguish the sparks which arise from the funnel of the locomotive? Experiments are in progress while this is being written, but the solution does not seem to be yet at hand. Since the first locomotive was created there has been a constant menace from fire to properties adjoining railway lines. The New Zealand Government, more practical than others, offered years ago a bonus of £3,000 for the production of this contrivance. That offer still, apparently, holds good.

The Full Value of Coal. There are, of course, many larger problems in the same field. The man has yet to arise who will teach us the means to extract full value from the coal we burn. It has been computed that while it took thirty years for 100,000 men to build the Pyramid of Cheops, we have each year to win from the earth a bulk of coal sufficient in dimensions to build two hundred of such pyramids. And six-sevenths of that coal is wasted. Edison tells us that, properly used, a bucketful of coal should drive an express from London to Manchester, and a few tons send a steamer across the ocean. So long, however, as we permit practically the whole of the energy in our fuel to escape as waste, so long must we go on burning tons where pounds should suffice; and so long must we expect to see the atmosphere of our great cities dulled and deadened by the pall of smoke arising from their myriad furnaces.

The question of smoke-consumption is another which claims attention. Invention after invention has been recorded at the Patent Office, but still our industrial centres lie grimy and hideous beneath their black mantles; and London fogs, with coal smoke as the dominant constituent, represent each year a loss of many millions sterling to the community, to say nothing of the sacrifice of life involved. Who shall deliver us from the thraldom of the fog for which London is notorious? Sir Oliver Lodge has in mind the germs of a great invention to this end, but whether his duties in other fields of activity will permit him to work it out is greatly to be doubted.

Lights in Tunnels. Every omnibus conductor has now his little portable electric lamp—a contrivance which fifty years ago would have been deemed an impossibility. Is it too much to hope that some day a man of ideas will give us a light upon a bigger plan which will pierce the fog, if not dispel it, as we take our way by train, by motor, or by steamer? Experimental investigation is tending towards this desirable consummation; there is ample time for the right man yet to make up his mind to be first to arrive—and do so.

Some little time ago a railway worker discovered a method of economising coal while developing a greater head of steam upon the engine he drove. He was fortunate enough to find a sympathetic board of directors who put his scheme at once into operation. A good many years earlier a man of a like cast of mind published particulars of a scheme for lighting tunnels upon railways. His plan was for an installation of electric lamps, which would be automatically kindled the moment the flange of the wheels came in contact with a certain mechanism. When the train passed out of the tunnel, the lamps would be automatically extinguished. It was pronounced by experts simple and feasible, but we still ride, often enough, in lampless trains, through pitch-black tunnels.

Little Things to be Invented. The lighting and ventilation of tunnels offer fields worthy the attention of the inventor. The desire to gain more leisure for play induced a youth to fix the first automatic valve upon an engine; an act of which he thought nothing, but which revolutionised the whole science of steam engineering. Perhaps some genius, held up in an unlighted tunnel, and so debarred from reading his SELF-EDUCATOR, will be inspired to solve the problem; as Edison was driven by want of light to invent the incandescent lamp.

So many things the world needs, that instead of pausing to marvel at what has already been

accomplished, we must wonder that so much has been left undone. We plough and reap by machinery, we lay bricks and make matches by machinery; yet we have to paper our walls by hand, just as they always have been papered since this method of decoration was first adopted. Who that has had a breakdown on a bicycle or motor-car has not yearned for a "monkey-wrench" which could be adjusted in an instant? Why, as domestic servants are able to sweep carpets by simple little mechanical sweepers, should they not be able to scrub a floor as easily and well? Such a machine would save infinite labour, and, incidentally, prevent many cases of "housemaid's knee." There are many excellent fountain pens on the market. We want one still better; one which can be filled with ease, and which will not soil our hands and clothes, and make disfiguring blots by overflow of ink.

The New Typewriter. Handwriting will soon become the pastime of the writer of private letters. We want simpler, cheaper typewriters. Typewriters cost to-day practically as much as they cost when first invented, yielding an enormous profit to those that have the monopoly. The man with genius for the task will give us a machine for which the paper need not be changed every few minutes; for which the "carriage" has not to be returned by hand; and, most important of all, so easy of manipulation that the nerves of the operator, and those of the people about him, may be spared the irritation and strain which the clatter and rattle of the present noisy machines cause. We want a typewriter which shall be practically silent in operation and shall not "jar" the hands and arms of the typist. There is a world-wide market for a machine of this description.

Baths for Every House. Our forefathers were not extravagant in the direction of baths; they left that to the "heathen" East, where cleanliness is next to godliness—is, in fact, an essential preliminary to worship. We of the present generation have not made a sufficiently material advance in the provision for the wherewithal for ablutions to entitle us to make any boast. The poor man returning from his dirty, perhaps noisome, toil, if he need a bath, must take it in what he calls the "houseplace"—*i.e.* the general living room, or go unbathed. An attempt has been made to introduce a bath into cottages by sinking it beneath a detachable floor. Human ingenuity should not be exhausted by this effort. No plans for the building of cottages should be passed which omit a full-sized bath. The question of water supply may be a serious one; we need some simple little reservoir in which every cottager may conserve a proportion of the rain-water which now runs to waste down his drains.

The Need of the Dentist. Dentistry is a much more ancient art than some of its professors realise. They knew how to extract and "stop" diseased teeth in ancient Assyria, Egypt, Phœnicia; and they made artificial teeth three thousand years ago. Then men forgot all they had learned, and hundreds of years were to elapse before dentistry became exalted out of the keeping of barber and clown. Even now, it is only in its infancy. Men with many degrees would feel highly aggrieved if their patients told them frankly what they thought of their work. After all the labour and study which dentists have devoted to their profession, it remains a fact that while their work is of the highest importance to the health of their fellows, it is carried out at a great cost in suffering to the patient. Given the assistance of a good anæsthetist, any clumsy fellow can extract the tooth of a healthy patient; it is the preventive dentist, so to speak, who renders us the greatest service. And his methods are barbarous. The "stopping" of teeth is the most painful operation, the most trying to the nerves to which a sensitive person has to submit. The call is for the man who can drill and fill a tooth as painlessly as he can extract another under gas; and who can furnish a filling which shall be not so expensive as gold, yet capable of withstanding the disintegrating action of saliva.

The Mechanical Side of Books. In the book world fortune awaits the man with ideas. Reference is made, not to authorship, but to the mechanical side of production. Paper, covers, and method of binding are all open to attack. At present we have not a paper which will satisfactorily reproduce a photographic block unless the surface be so highly burnished as to make reading intolerable, or so heavily charged with clay as to make the book weigh pounds instead of as many ounces. What is wanted is a good, light paper, with a smooth surface which will reproduce pictures equally well with letterpress. For covers, a substitute is needed for the strawboard or millboard now commonly in use. As to binding, there are two avenues open to the inventor. The simpler one is to find a way of stitching the periodicals, so that they may open out flat, instead of, as is now the case, shutting when released for a moment by the hand, as if actuated by a spring. The one evil of modern magazines is the way in which their pages have to be wired together.

Book-binding by Machine. There is a larger problem in the binding of books. If machinery can convert a pig into sausages; produce boots from strips of leather; turn out matches ready-made and boxed; set up the type and print a paper at the rate of 50,000 an hour—if machinery can do all this and a thousand other wonderful things, why cannot it also stitch the pages of a book and fasten on its covers? There is no other reason than that the necessary machine has not yet been devised. "Impossible," says the man who has not given thought to the project. "Preposterous," they said when Faraday was toying with the needles which were to give us the electric telegraph. "Madness! Impossible for a steam-engine to work except upon a solid stationary base," declared the President of the Royal Society, when the principle of the first steamboat was explained to him. For long machine builders wanted a machine which would uproot potatoes, "top" and tie them up in sacks, and for long they declared

such a machine impossible. But a family of Yorkshire farmers have made such a machine—out of scrap-iron, beaten into shape in their own little forge. So that those who look for a machine with which to bind a book need not wholly despair.

Many men have made fortunes from boots. Not all have deserved their gains. Man must be shod, so submits to the style and fit imposed. But we are no better off in the matter of comfort than were our forefathers of long ago; indeed, we do not fare so well. It is still the case that our feet have to fit our boots, not the boots our feet. A fashion in shapes is arbitrarily fixed, and the foot must conform to it, whether it be broad or narrow, long or short. Boots made by the careful man from one's own last have to be grown into, as it were. The laborious lacing of boots should not be necessary. We cannot go back to the unventilated sidesprings, and no buckle has yet proved satisfactory. There is abundant scope here for the inventive. Papier-maché proves impervious to the weather when employed as a material for houses; might not it make a good substitute for leather?

Better Shoes for Horses. Horses, too, might be better shod. A scandal of daily life is the strain to which these friends of man are submitted in their attempts to get a foothold upon the glassy asphalt over which they have to drag their loads. After all the ages during which horses have been shod, the farrier should be capable of something better than a crescent of smooth iron, which, while saving the hoof to a certain extent from the effects of the "hammer, hammer, hammer on the hard high road," causes the hoof to break away around the many nails which must be driven into it in the course of a horse's career, and, at the same time, does not enable the animal to get any real purchase upon a road which is at all smooth. Horse-masters should lend encouragement, too, to the man who will turn out a cart capable of being nicely adjusted when a heavy load is to be carried. The right position of a load for uphill is wrong for downhill, and *vice versâ*; but present-day carts admit of no alteration, and so our horses' withers are wrung. Years ago a man produced a mechanism which enabled the driver, by the turn of a lever, to bring forward or force back the body of the cart, so as to balance the load and ease the horse uphill and down. But the invention, simplicity itself, and perfectly efficacious, has never come upon the market. Perhaps it was too manifestly humane to succeed;—a more drastic form of bearing-rein might have been more acceptable.

A man with a bent in the right direction might do something to improve the umbrella, which is now as it has been through all its long history, nothing but a shelter for the hat. Tailors who give us "waterproofed" cloth for our coats might submit the cloth for our trousers to similar preparation. To keep the shoulders and knees immune from damp is very desirable, but chill seizes one just as readily from damp trouser-legs.

The Automaton. Upon every tram, 'bus, train, and other vehicle we ought to have a post-office; in every important thoroughfare there should be a public office in which one could see a directory upon payment of a penny. Telephone call offices ought to be multiplied in all streets and public places. Automatic buffets similar to that in the Thames Embankment Gardens should be in every public park and square lying upon the route of the poor. The automatic buffet is one of the institutions of the future.

Such are a few of the directions in which the inventive may turn their attention. There are many more, though not all appeal so directly to the individual. Every pillar-box should be a local guide, telling not only, as some now do, the time of next collection and address of post-office; but the address of police-station, fire-station, and so forth; and, further, should supply, on the automatic plan, all requisites for a letter. We may even hope some day to see pillar-boxes developed so as to automatically receive telegrams, to be dispatched by the sender by pneumatic tube to the nearest telegraph-office.

The Children. There is a fortune for the man who evolves an entertainment for children. Not all parents desire to take their children to pantomime or circus. The former is not invariably the most delicate form of entertainment extant; the comedian who can always keep humour and vulgarity apart is not found on every stage. The circus frequently becomes wearisome to the child. The children want their own Grossmith; the man who will sit down on the platform and tell them the prettiest stories in the world, sing them dainty little songs; and have upon his programme an item or two of the frankly "funny" character, but rigidly mindful of propriety. To such an entertainment one half of London would take its children, and country cousins would accord it as definite a place upon their programme as the Abbey and St. Paul's.

The child at home, too, is worth cultivating. We want more games—games with some purpose, which teach a little as well as amuse. There are millions of pounds in toys and games. Originality in Christmas crackers, a departure from caps and inane doggerel, is a feature which is developing, but there is still room for a tremendous advance.

Every trade and profession and vocation is overcrowded, we are told by those who are in them. As a fact, however, there is not a walk in life in which men and women of ideas may not launch out upon new lines, and gain wealth and reputation.

To be continued

BEGINNING AND CONTINUITY OF LIFE

How to Study Biology. Homology and Analogy in Structures. Classification. The Process of Reproduction and the Continuity of Life

By Dr. GERALD LEIGHTON

How to Study Biology. We now come to consider the question of the methods of study in biology. How are we to set about our inquiry into the various aspects of living creatures? What methods are we to employ? For our purpose those methods may be summed up in the statement that we shall endeavour to ascertain how living things resemble each other and differ from each other, and especially how these differences are brought about. Our study of life is mainly that of likenesses and unlikenesses, their origin, development, transmission, and evolution. It is a study, therefore, partly of structure, in so far as we compare the structures of animals; partly of function, in so far as we compare the various ways in which the structures perform the tasks of life. If the matter be probed to the bottom, it is seen that as a matter of fact an animal can only resemble another or differ from another in one or both of these ways. All other distinctions depend ultimately upon these.

The most casual observer cannot fail to notice that there are likenesses and unlikenesses in animals. Watch a cat at play, and we are immediately reminded of a tiger. Observe the flight of a bat in the evening, and that of a bird is at once suggested. The environment and motion of a whale seem to be those of a fish, and so on. These points of resemblance are quite obvious, but many resemblances are, on the other hand, only discovered after most careful comparison and study. Not only so, but there are different kinds of likenesses as well as different degrees. One part of one animal may be like that of another in its structure, but quite dissimilar in function; while, on the other hand, two widely differing structures may perform identical functions. For example, the wing of a bat and the wing of a bird are both used for purposes of flight; they perform similar functions. Moreover, they are structurally somewhat similar, differing in detail. But the wing of a bird and the wing of an insect, although both alike are for flight, have nothing in common as regards their structure. In other words, we find that likenesses are due either to parts exhibiting homology or analogy, the difference between these being very important.

Homology Defined. Homology is defined as "identity of structure in parts or organs, independently of function." Thus it makes no difference whether a structure is used for walking, climbing, swimming, or flying: if it be identically of the same structure it is an example of true homology. The part is a *homologue* of some other part with which it is compared. Thus the arm of a man, the wing of a bat or bird, the flipper of a whale, and the pectoral fin in some fish, all being built upon the same morphological type, are said to be homologous. The importance of noticing homology where it exists is this, that homology points to a common origin of the structures, and is therefore of great consequence in classification. It is of no significance from this standpoint that the arm of a man and the wing of a bird are used for different purposes; they are built upon the same fundamental plan, and are therefore homologues. It follows from this that structural likenesses are by far the most important guides to classification, the functions of similar parts being so very dissimilar as to put function out of court as a reliable guide to classification.

Analogy. On the other hand, we find *different* organs in different animals engaged in the performance of the *same* functions, and such organs or parts are said to be *analogous* with each other or *analogues*. Analogy in biology, therefore, means "identity of function quite independently of structure." Thus the wing of an insect and that of a bird are analogous organs, both being used for flight, but they have nothing in common in their structure. They have no common type of structure, but perform similar functions. But it must not be forgotten that in many cases analogous organs have more than this superficial resemblance of similar function: they are often constructed upon the same structural plan, in which case they are both analogous and homologous. Thus the leg of a man and the hind leg of a dog, being built upon the same type and used for the same purpose, are both homologous and analogous organs.

Classification of Living Creatures. The next point for consideration is that of classification of living creatures, which is a matter of convenience of description and reference. This, again, is founded upon morphological likenesses and differences, the result being the arrangement of a number of very diverse living objects into a number of smaller or larger groups, according to their greater or less structural resemblance to each other. A system of classification on these lines is good or bad according to the nature or number of the characters which are taken as determining the likenesses. There can be no hard and fast rules laid down. Classification is not a product of nature, but of the human mind; it is useful and convenient—indeed, a necessity, but purely artificial. The term "artificial" is, however, restricted to systems of classification which depend entirely or chiefly upon external and superficial resemblances. Thus, according to an artificial classification, a whale would be placed

upon the same footing and in the same group as a fish, in spite of the fact that it differs from a fish in every essential point of structure, simply because it so happens that it lives in the water.

Natural Classifications. So unsatisfactory are such "artificial" classifications that biologists have given them up altogether and adopted what they term natural classifications, which endeavour to group creatures into divisions depending upon a due consideration of all the essential points of structure presented by animals, apart altogether from the external shape of the animal or its habits and surroundings. When looked at in this way, a whale is found to be one of the mammalia and not a fish at all, in spite of its shape and aquatic habits. Such a natural or philosophical classification involves due consideration of true resemblances and differences which, as we have seen, depend upon similarity of structural type. The more perfect such a classification is, the more information it gives. Thus, if a whale were classified as a fish, all that would be expressed by that would be that its body was fish-like and its habits marine; whereas by placing the whale among the mammals, we are told at once that whales have their young born in a comparatively helpless state, that the mother has special mammary glands for the nourishment of offspring, and that hairs are found on some part of the body, characters which no fish presents. In a word, classification depends upon a careful discrimination between homologies and analogies, likenesses of analogy alone being entirely disregarded, likenesses of homology being relied upon as the only safe guide to affinities.

A Species. Having clearly grasped these essential principles of classification, all that is necessary here is to take an example and show how the principles are applied. Before doing so it may be well, however, to say a word about that much-discussed term a species. The animal *kingdom* is subdivided into *sub-kingdoms*, these into *classes*, these into *orders*, these into *families*, these into *genera*, and finally these into *species*. A species is the smallest *definite* division of animals that naturalists accept, each species or "kind" of animal resembling all its individual members in all essential characters of structure and being able to breed amongst themselves so as to produce similar individuals to themselves. If a number of such individuals have some peculiarities in common, they are termed a *variety*, and if these peculiarities are constantly present in their offspring, these are sometimes termed a *race*. Thus all dogs belong to one *species*, the species *Canis*, although there are many varieties of dogs. To distinguish a variety from a species is sometimes a matter of very great difficulty, simply because nature does not divide animals in this way at all, though man does so for convenience sake.

The classification now adopted by naturalists will perhaps be better understood if we take an actual example, and see how it is applied in practice. If we regard the domestic dog, with all its subordinate varieties, as a single *species*, we have to notice in the first place that it is technically known by a *double* name, and is called the *Canis familiaris*. All species are thus known by "binomial" designations, the *second* name being like a man's Christian name, and being distinctive of the *individual*, whilst the first name is like a man's surname, and indicates the group or, technically, the *genus* to which the individual belongs.

An Example of Classification. The dog, then, whilst individually recognised by the epithet *familiaris*, belongs to the genus *Canis*, in which are included other related species, such as the wolf (*Canis lupus*) and the jackal (*Canis aureus*). The genus *Canis*, again, belongs to the family *Canidæ*, including other genera, such as the foxes (*Vulpes*). The family *Canidæ*, again, is one of a number of families, such as the lions, tigers, and cats (*Felidæ*), the bears and racoons (*Ursidæ*), the hyænas (*Hyænidæ*), etc., which together constitute the order of the *Carnivora*, or beasts of prey. The *carnivora*, again, constitute one of many orders of quadrupeds which are distinguished by suckling their young and by other common characters, and which collectively constitute the class *Mammalia*. Finally, the class *Mammalia* is united with the classes of the birds, reptiles, amphibians, and fishes, to constitute the great primary division of *vertebrata* or vertebrate animals; since all these classes agree with one another in the fundamental character of possessing a backbone or vertebral column, or an equivalent structure. Condensing the above, the zoological position of the dog, expressed in full, would be as follows:

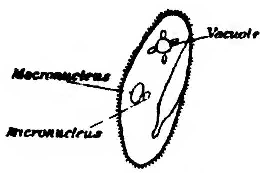
1. Sub-kingdom: *Vertebrata*.
2. Class: *Mammalia*.
3. Order: *Carnivora*.
4. Family: *Canidæ*.
5. Genus: *Canis*.
6. Species: *Canis familiaris*.

In an ordinary way it is quite unnecessary to employ in practice any of the above names except the last or *specific name*, since that implies all the others. (Nicholson.)

Likenesses and Differences. When we apply all these methods of study of living creatures to any one form, in order to complete its description and classify it correctly, we begin with the simplest possible structural tests, and proceed to more complicated likenesses and differences. Thus the very first point that would arise would be the number of cells in the creature, whether *one only*, or more than one; in other words, whether we were dealing with a unicellular protozoan or with a metazoan (as all many-celled animals are termed). If the former were the case, the next inquiry would be directed to ascertaining whether there were any indication of specialisation of function in this single cell or not.

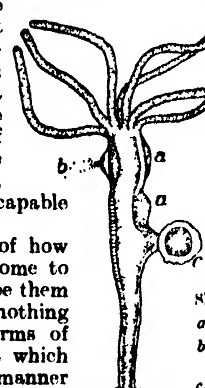
We have seen that most unicellular organisms exhibit no real specialisation of function, all parts of the protoplasm acting indifferently as organs of nutrition, reproduction, and relation. Directly we come to deal with multi-cellular or metazoan animals, however, we find certain cells being set aside for the performance of special functions, the first sign of the higher evolution of organised beings.

The Problem Re-stated. It is here that we come to the question of "How?" We have cleared the way to the study of this question in the preceding pages, and now approach the more interesting part of biology, which can only be understood, however, after a due appreciation of the methods of study already described. In order to be perfectly clear, let us re-state our problem. What can we learn from biological science which will enable us to realise in some degree how living creatures have been produced in the infinite variety in which we see them in the world? Various methods of investigation already enumerated are open to us. What do they teach us concerning the continuity of life, and the origin and transmission of new characters in living creatures? What do we mean by evolution, and how has it come about? What is the meaning and significance of heredity, and how does it tell in the world? Finally, how are all these all-powerful factors acting at the present time upon the highest product of evolution, Man himself? This is to be our study in the following pages. Without entering into technical detail, we may still hope to learn something of the infinite grandeur of the whole conception as it unfolds before us, and to rise from the study more capable of seeing life whole.



4. PARAMŒCIUM.

In approaching the question of how the manifestations of life have come to be so many and so varied as we see them to be in the world to-day, to say nothing of vast numbers of living forms of bygone ages, the very first point which demands our attention is the manner in which the life of one generation is continued into the next.



5. HYDRA.
Showing—
a. Sperm-sacs.
b. Discharge of Spermatozoa.
c. Ovum.

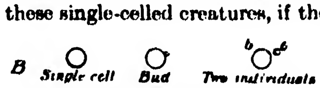
Continuity of Life. Everything depends ultimately upon this, and all the great biological problems of variation, natural selection and heredity centre round the great fact that there is a continuity of life from one generation to another by means of the protoplasm of the cell (in unicellular organisms), or of the germ cells (in higher animals). Curiously enough, this fact—which is obvious in those lowly organisms which reproduce by simply dividing into two—has been recognised in the higher animals only within recent years. In modern biological literature it is spoken of as the "continuity of the germ-plasm."

6. REPRODUCTION BY FISSION.

The various modes in which the continuity of life is made possible are, in other words, the methods of reproduction in living creatures. It has been already mentioned that the very simplest of these methods consists in the division of a single-celled organism into two separate individuals, by a simple process of *fission* or *budding* [6 and 7]. The former process, fission, is seen in bacilli, in which a constriction appears about the centre of the cell and ultimately divides the cell into two. In these simple examples it is quite obvious that all the characters of the single-celled organism *A* or *B* (both of them being undifferentiated masses of protoplasm with no specialisation of function) will be present in the next generation *a a* and *b b*, their offspring.

Except in their size at first, *a a* and *b b* are exactly like *A A* and *B B* as far as we can determine. They could hardly be otherwise, inasmuch as the latter produced the former by simply giving up part of themselves. In their turn, *a a* and *b b* having grown to maturity, will themselves divide and thereby produce the next generation with similar characters to *a a* and *b b*, as well as to *A A* and *B B*. So like produces like, and unless there were such a thing as variation in protoplasm, the offspring of *A* and *B* would never be anything different in any respect from *A* and *B*. But leaving the question of variation for later treatment, the immediate point is that the continuity of life depends upon the protoplasm of one generation being the basis of the appearance and growth of all succeeding generations, which therefore resemble *more or less* their ancestors.

A Race Dying Out. Such methods of production as fission and budding, the simplest of all reproductive processes, are, of course, non-sexual. The unicellular plant is not specialised in this way. But a very little higher in the animal world we find organisms departing from this extremely simple mode of reproduction and exhibiting processes which foreshadow the true sexual method. Some of these single-celled creatures, if they be separated and isolated and closely observed, are found to be limited in their powers of reproduction by simple division. The time comes when they will no longer continue thus dividing into two. This comes gradually, after the offspring have shown signs of deterioration in size and activity, in fact, all the symptoms of a race dying out.



7. REPRODUCTION BY BUDDING, OR GEMMATION
(as occurs in many globular single-celled organisms).

This foreshadowing of more complicated methods of reproduction is of much importance and significance. The process is admirably seen in the simple little creature found in an

infusion of hay water, known as *Paramœcium*, or the "slipper animalcule," the latter name being given on account of the shape of this organism. Paramœcium is just visible to the naked eye as a whitish speck. Under the microscope it is found to have a complicated structure for a single-celled organism [4].

The Maintenance of Vitality. This little creature reproduces itself in two ways, sexually and asexually. The asexual reproduction is a very quick process, and consists simply in a fission of the cell transversely into two parts, this being preceded by a division of the nuclei within the cell. The significant point is this: that the asexual method just mentioned cannot go on indefinitely. If a single paramœcium be isolated in a vessel by itself and allowed to reproduce in this way undisturbed, it is found that after a certain number of generations have been produced asexually, some of the resulting offspring show signs of deterioration. They are smaller than the first ones. If the process go on still further, this result becomes more and more pronounced, until ultimately the power of reproduction by this method disappears. In a word, it is necessary to introduce a new paramœcium in order that what we term the vitality of the protoplasm may be maintained at its proper standard of physiological activity.

Two Sexes in One. If this be done, a very remarkable series of changes follows. What appears to be a process of sexual reproduction takes place. At any rate, conjugation of two individual paramœcia occurs, by means of which an exchange of protoplasm is effected between the two cells. It is the simplest case of sexual reproduction we know, and yet in its detail is really somewhat complicated. The point to note is that two paramœcia come into contact by their ventral surfaces, and that this is followed by a series of changes in their respective nuclei during which each fuses to some extent with that of the other, after which the two organisms separate from each other. The nuclei which unite are called male and female. On the completion of the process each individual divides, so that from the original two parent organisms four individuals result.

"The fundamental act in the whole series of these complex changes is the fusion of the male pronucleus of one individual with the female pronucleus of the other. But as far as it is possible to ascertain, the male and female pronuclei are identical, unless the fact that one migrates while the other remains stationary can be considered a difference of any importance. There is, therefore, apart from this act of migration, no differentiation into a male spermatozoon and a female ovum. And there are reasons for regarding this phenomenon of the fusion of identical masses, but derived from two individuals, as a rudimentary sexual act; that is to say, that in some such way as this sexual reproduction first arose. And we speak of this act as one of *Conjugation* in order to distinguish it from that definitely sexual one where the male element can be distinguished from the female in virtue of its size, form, and movements." (Mudge.) These half-way processes, if we may use the term, are of supreme interest to the student of biology. They bridge the gulfs between the simple and the specialised, and it is because of their existence that we are forced to believe in the gradual evolution of the complex from the simple, and in the oneness of the great plan which underlies the whole creation.

Steps in Evolution. We have now referred to reproduction in two of its modes of occurrence, by simple division of a one-celled organism into two as in an amœba or a bacillus, and secondly as a rudimentary sexual act in the conjugation of Paramœcium. Next we may turn our attention to another little creature termed *Hydra* [5], in which we shall find still further elaboration for the purposes of reproduction. Hydra is a fresh-water organism to be found in ponds and sluggish streams, frequently attaching itself to some of the water-plants or other floating objects. It can be observed quite easily by simply confining it in a transparent glass vessel in which is placed some water-weed. One end of this creature is seen to be attached to some object in the water, while the free end carries a number of minute tentacles just visible to the eye.

The reproduction of hydra is remarkable in that it takes place in two distinct ways. During the spring and summer hydra reproduces itself rapidly by an asexual process of budding, but later in the year, when the temperature falls and food is more difficult to obtain, a very extraordinary thing happens. A true sexual reproduction takes place. "At this period two little eminences appear upon the surface of the body, one being conical in form and situated in the upper part just behind the ring of tentacles, and the other lower down and somewhat rounded in form. The upper one is the *testis*, and the lower one the *ovary*. The ovum or egg becomes fertilised and undergoes an immediate preliminary development, by which the embryo becomes encased in a hard investment, and then it sinks to the bottom of the water, where it remains dormant until the early spring of the next year." (Mudge.)

Two Phases of a Life-history. We have, therefore, a life-history of two distinct phases, the one being that of a number of individuals which have been developed asexually, the other a number developed sexually. The asexual parent produces offspring asexually which develop sexual organs and reproduce the next generation sexually. These in their turn reproduce asexually again, and so on. This alternation of an asexual individual with a sexual one occurring in the life-history of a species is called an *Alternation of Generations*. It is not uncommon in the sub-class of animals to which hydra belongs. It carries us one step further in the methods of reproduction, a process which in all the higher animals is carried out only by the sexual method. In that method certain cells, the ovum and the sperm, are set aside for the special process of reproduction, and in their intimate structure is the mechanism by means of which the characters of the species are transmitted.

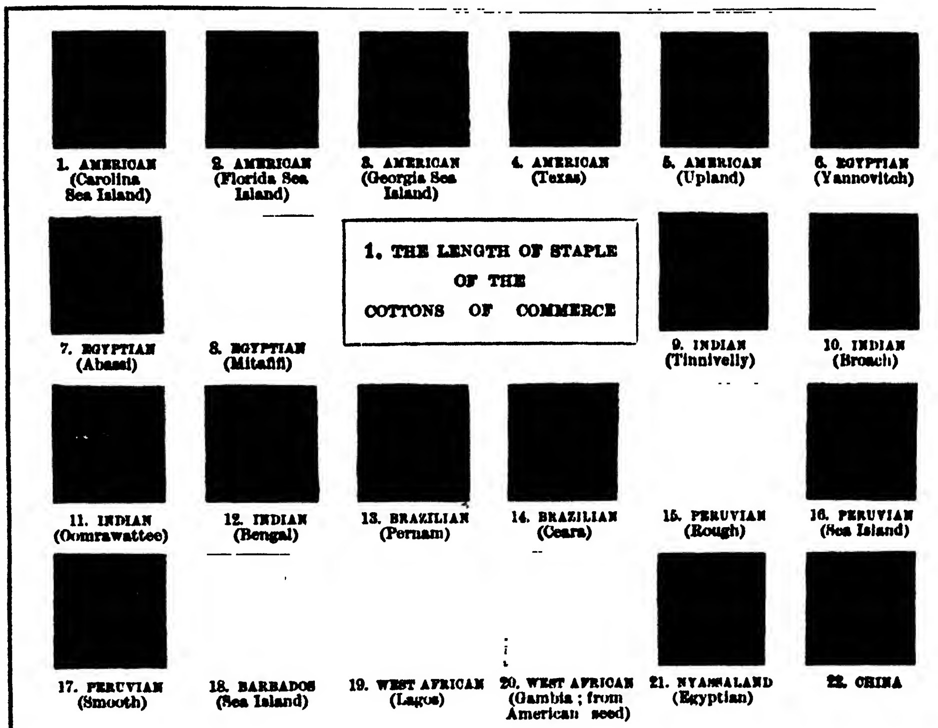
THE BEGINNINGS OF COTTON

The Development of the Cotton Industry—continued. The Cotton Field. Cultivation and Preparation of Cotton for Shipment

By W. S. MURPHY

South American Cotton. Resuming our study of the world's sources of cotton, we now turn to the product of South America. It is a curious fact that, while the natives of many tropical countries have produced cotton for centuries to supply their own needs, raw cotton has seldom been regarded by these populations as an export commodity. During long centuries the natives of India sold cotton cloths to foreigners without a thought of offering them raw fibre; the Chinese had spun and woven cotton for many centuries, and only awoke to the existence of a market for cotton fibre late in the nineteenth century; and many other nations and tribes, more or less barbaric, have bartered gold, pearls, shells, amber, gums, and fruits with the white stranger, while reserving the raw cottons of their fields for home use.

South America, soon after its discovery, became the prey of European adventurers there, and the Spaniards found a land better suited for colonisation than the northern half of the New World. In the Brazils, Bolivia, and Peru the invaders found soils suitable for cotton cultivation and a certain amount of production by the natives of those regions. By the year 1786 the South Americans had developed a large export trade, sending 5,000,000 lbs. of cotton to England alone. Six yea s later, however, the fibres of Peru and Brazil encountered the serious competition of the produce of Florida and the Mississippi valley. During the British-American War of 1812 the South Americans had an opportunity of re-capturing the English market, and again in 1861, during the American Civil War. But the South American lacks the business energy of his northern rival, and though the cotton supply of Peru and Brazil is always worth considering by cotton buyers, it is small compared with that of the United States.



1. THE LENGTH OF STAPLE OF THE COTTONS OF COMMERCE

Egyptian Cotton. Egypt was for some time regarded as the original home of the cotton industry, and very probably Egypt was

the seat of cotton manufacture in times long forgotten; but the definite assertions of Egyptian priority in cotton manufacture were founded on an error. Investigators wrongly supposed that the linen wrappings of Egyptian mummies were cotton. Such revelations of error ought to make historians of industry cautious and tentative in their conclusions. It is certain, however, that cotton was grown and *spun in Egypt long* before even the era we name *ancient was begun. Here the stay-at-home character of cotton strongly* shows itself. Not till 1821, under the strong rule of Mehemet Ali, did Egypt begin to export cotton. That year

us from disaster should the supply from the United States for any cause fail us. In the table given below the position of the cotton market at the beginning of the twentieth century may be seen at a glance.

Cotton Growing in the Empire. About the middle of the nineteenth century, when the cotton trade was extending so swiftly that it threatened to dwarf every other branch of the textile industry, a great doubt arose in the minds of the far-seeing members of the trade. Without the stern lesson of the "Cotton Famine," as the dearth caused by the American Civil War was called, these men perceived the unstable

TABLE OF COTTON FIBRES AT PRESENT IN USE

Country of Growth.	Variety.	Length of Staple. See Fig. 1.		Diameter of Fibre.	Average Counts of Yarn.	Description.
		Min. Inch.	Max. Inch.	Inch.		
AMERICA— Area of crop, 27,000,000 acres; Product (1903), 2,400,000 tons; Export to U.K., 607,650 tons	Sea Island	1⅝	2	1/[illegible]	130 upwards	Long, fine, silky, easily bleached; the best cotton.
	New Orleans	1	1¼	1/[illegible]	40–60	Most reliable of American cottons, some varieties white, others creamy.
	Upland	⅞	1	1/[illegible]	30–40	Soft, and adapted for weft.
	Texas	⅞	1	1/[illegible]	40–50	Fine, but rather dirty and dull.
EGYPT— Area of crop, 1,375,000 acres; Product (1903), 5,000,000 cwt.; Export to U.K., 2,780,000 cwt.	Mitafifi	1·3	1·6	Average 1/[illegible]	80–180	Brown, varies in quality.
	Abassi	1·4	1·8		60–80	White, mixes well with Sea Island, though a trifle harsh.
	Ashmouni	1	1·4		—	
	Yannovitch	1·3	1·6		80–120	Soft and fine, but brown in colour.
BRAZIL— Total Export (1903), 28,000 tons; Export to U.K. 18,000 tons	Pernam	1·4	1·50	1/[illegible]	40–60	All Brazil cottons are white and hard, giving yarn a wiry feel.
	Ceara	1	1·2		26–36	
	Maranham	1	—		40–50	
PERU— Total Export (1903), 7,530 tons; Export to U.K., 3,230 tons	Sea Island Peruvian	1	1·7	1/[illegible]	40–50	
	Rough Peruvian	1·2	1·5	—	30–40	Harsh, mixes with wool.
	Smooth Peruvian	1	1·1	—	30–40	Soft, silky and clean.
SMYRNA— Total Export (1902), 4,462 tons; Export to U.K., 254 tons	Yerli	⅞	1⅛	1/[illegible]	20–36	Strong, harsh, fibres irregularly twisted.
INDIA— Area of crop, 15,000,000 acres; Annual crop, 400,000 tons; Export to U.K., small amount	Surat	·80	1·20	1/[illegible]	16–26	Good working cotton.
	Bengal	—	·80	1/[illegible]	Low counts	Except when grown from Sea Island seed, Indian cottons are poor in quality and short in staple.
	Broach	·6	1	—	"	
	Rangoon	·8	1	1/[illegible]	"	
CHINA— Annual crop, 300,000 tons; Export to U.K., 662 tons	Common	⅞	1	—	20	White, rough, short in staple.
WEST INDIES— Area of crop (1904), 14,000 acres; Product (estimated), 5,000 bales	Sea Island	1¼	2	1/[illegible]	80–120	Fair, but irregular in quality.
	Native	1	1·4	1/[illegible]	—	Lacking uniformity in colour.

944 bales were sent out, chiefly to England, and in the years following the amount rapidly increased, the average annual production being about five million hundredweights.

In sketching the history of the cotton sources we have detailed only those which are of prime importance in the cotton market. Other and smaller contributors there are. China, according to expert estimate, grows over 300,000 tons of cotton annually, but of this enormous total only about 45,000 tons are exported, the greater part being consumed in the country. Asia Minor, Cyprus, Java, and West Africa send small contributions; but these would not save

basis of the cotton supply of the world. The preponderance of the United States in the raw cotton market constituted a grave danger; that the main supply of so vast an industry should be liable to disturbance by purely local causes was rightly considered to be a serious risk. How true were the prognostications of those cotton manufacturers the Civil War proved in a fashion more emphatic than pleasant. In later years, the vast additions to the productive capacity of the United States notwithstanding, the menace has become even more threatening, and all those whose interests are connected with cotton, all who are in any way dependent on

the prosperity of the cotton trade, ought earnestly to seek to broaden the basis of the supply of raw material.

West Africa. While, in 1850, many manufacturers expressed alarm, and exclaimed, in the usual manner of alarmists, that something must be done, but did nothing, one man, Thomas Clegg by name, a citizen of Manchester, took wise action. We have called special attention to the stay-at-home disposition of cotton out of no idle motive. If there are tribes producing cotton for their own consumption, they are likely, if inducements are offered, to produce for the outside world. These cotton-growing, non-exporting peoples are like subterranean waters, which, in dearth of rains, can be tapped for supply. At the very least, wherever you find a tribe producing cotton for home consumption, you have a cotton field which may be made indefinitely more productive by the application of scientific methods of culture. These truths were perceived by Thomas Clegg. Knowing that the natives of West Africa produced cotton for themselves, Mr. Clegg established a native agency on the coast, buying cotton from the natives, and encouraging them to further production. His efforts met with considerable success. In 1852 he gathered 1,810 lbs.; in the year following, 4,617 lbs.; in 1859 the amount gathered by Clegg's agency was over 70,000 lbs. Though we have no further record of this man, his work has lived on, and from West Africa there has always been a continuous, though small, supply of cotton.

Organising the Cotton Supply. Lancashire cotton spinners as a body took some time to act, but in 1857 they formed the Cotton Supply Association, the constitution and methods of which exhibited the enterprise of its founders. This organisation of business men aimed at no direct profit, its objects being: (1) To supply seeds, machines, and practical instruction to those willing to engage in cotton cultivation; (2) To ascertain the capabilities and peculiarities of the various districts of the world where the plant may be, but is not at present, produced for export. For some time it seemed that this association had the power to solve the problem, and during the first years of its activity the outlook was hopeful. Cotton-growing was begun in Greece, Turkey in Europe, Tunis, Liberia, Gold Coast, Benin, Old Calabar, Australia, Cape Colony, and Natal. The association helped to renew the vigour of production in Cyprus, Asia Minor, Cuba, Peru, Barbadoes, Batavia, Java, Ceylon, and all parts of India. The calamity the Cotton Supply Association was born to avert came too soon, and almost destroyed it. We do not say that the Cotton Supply Association has failed; a larger, more comprehensive scheme of action was needed, that is all.

2. THE COTTON PICKERS

British Cotton. For forty years manufacturers as a body allowed the question of the cotton supply to sleep, practically starving the Cotton Supply Association, and trusting to the power of the market to call in supplies according to need. Near the close of the nineteenth century, however, the power of the speculator in the cotton market and the increasing demand for cotton both in the United States and Europe gave rise to acute uneasiness. At the beginning of 1902 the fears of the most pessimistic were more

than justified; during that year and the two succeeding years there was a shortage in the cotton supply, with the result that many mills in Lancashire and on the continent were run on short time or entirely closed, inflicting loss on both operatives and employers, and damaging the trade generally. Instant action was demanded, and the British Cotton Growing Association was formed in 1902, with a guarantee fund of £50,000 and with the avowed object of extending the cultivation and growth of cotton throughout those parts of the British Empire where the conditions might be suitable.

Cottons of the British Empire. A council composed of representatives of every important cotton interest was formed, and the capital raised. Effort was first directed to re-establishing the cotton-planting industry in the West Indies and improving the culture of cotton in India. British Central Africa and West Africa also claimed the attention of the association. By October, 1903, it was seen that the field of operations required a larger capital, and the guarantee fund was raised to £100,000; this sum was got without much difficulty. Next, in 1904, it was decided to incorporate the association by Royal Charter, with a capital of £500,000, and on August 27th the charter was granted. On this new basis the work was vastly extended, and the active co-operation of the Colonial Governments everywhere secured. The British Cotton Growing Association now has stations in British East Africa, Uganda, Rhodesia, South Africa, the Soudan, and other places already mentioned.

In 1905 an Exhibition was held at the Imperial Institute, London, showing cottons from many parts of the Empire not then recognised as sources of supply. From the information then given the table in this section was compiled. By combining the table of cotton fibres with this, we obtain a clear view of the raw cotton production of the world.

The Processes of Cotton. A man likes to know the more important incidents in the history of his trade; but the practical processes have for him a deeper interest. The trade begun in primitive simplicity under the trees of tropical Africa, Asia, and America has woven itself into the complexities of civilisation, and, taking on the colour and character of its environment, has become complex in process and diverse in product. Cotton manufacture includes many trades and a great variety of commodities. We intend to take the student through every department, giving to each the proportion of attention which we think it merits, and this is our itinerary.

First: We shall view the cotton field, the cotton plant, the methods of culture, the varieties of cotton, the sources of supply, and the plans adopted for the development of British cotton resources; gathering on the cotton field; ginning; baling.

Second: The cotton is next seen in the stores of the factory, where selection is made for the production of any particular yarn required; we follow the mixture thus selected to the opener that breaks the lumps of cotton into fleecy masses; to the scutcher, in which the fleece is further opened out and formed into a flat sheet; to the carding machines, whose teeth unravel and pull asunder knots and snarls, blending and smoothing the fibre so as to make it lie close together in the form of a light, soft, thick rope called a sliver.

Third: We follow the preparing process further, and see the slivers combined and drawn on the drawing frames, slubbers, intermediate, and roving frames, successively; finally entering the spinning room, where the roves are put on to the mule spinners to be fine-spun and drawn; and then, emerging from thence, we see the stream of yarns part, one going up to the reelers to be hanked for the dyer and bleacher, another to the twisters, another to the lace factory, and yet another to the warping-room.

Fourth: The reeling and twisting machines

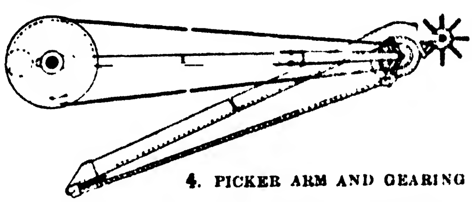
3. AUTO-COTTON-PICKER

and material, promoting by co-operation the welfare of each and all.

The Cotton Field. The cotton plant (*gossypium*—p. 222) will grow on almost any soil, though the best results are obtained from a deep loam, with good drainage. Sandy soils usually produce plants of small growth, because the moisture rapidly oozes away from the roots in light soils. No cotton planter need place too much stress on a particular kind of soil so long as he gets depth for the tap-root, because it is not difficult to remedy any slight deficiency in the quality of the soil. Climate is the main factor in cotton growing. The plant takes seven months to mature, and during that time the climatic conditions must be favourable. Frosts, quick alternations of heat and cold, torrential rains after sun, and other violent variations, are inimical to cotton culture. The ideal climate is a warm, wet spring, early summer of uniform temperature, and dry, cool autumn. The ideal is the un-

must now be utilised to produce warp and weft, the latter being wound on to small cops, while the former goes on to large bobbins.



4. PICKER ARM AND GEARING

Fifth: We are now at the beginning of the weaving process. The warp is formed, wound on the beam, heddled and drawn. Then we mount and dress the loom, it may be with jacquard or dobbie, or some fancy mountings.

Sixth: We have to learn the meaning of all the loom gearings, and acquire an insight into the secrets of weaving design.

Seventh: The part of the yarn set apart for the making of sewing-thread has to be taken in hand and put on the twisting frames, then bleached, dressed, gassed, polished, and spooled.

Eighth: Our pursuit of the fine yarns for lace-making must be resumed, and we see the warpers forming great warps on the heavy beams, while on the spooling machines the weft fills up the narrow spools between the plates of the slender shuttles; and then we lay the warp in place, set the shuttles on the comb-bar, adjust the jacquard apparatus, linking every wire to its thread of warp, and begin weaving.

These are the outlines of our study. Not infrequently we join with other textile students, and in company learn the relation of one branch of the textile industry to another, often using the same machines, imparting and receiving, exchanging methods

5. INDIAN CHURKA

attainable, and climatic conditions remotely approximate have spontaneously produced good cotton.

The cotton planters of the United States have brought cotton cultivation to a high pitch of excellence, and a survey of their methods will help us to form an idea of the work entailed.

Growing the Cotton. During the winter the old plants are grubbed up, and the land is turned over with the plough. As soon as the frosts have gone the soil is thrown up into ridges. If the soil be strong and able to bear a heavy crop, the ridges are only about two feet apart; but in poor soils as much as six feet is allowed. In a good spring, when the weather has settled early, sowing begins about the middle of March; but in some seasons it is advisable to defer sowing till well on in April, especially on the northern edge of the cotton belt. The seed is sown in the ridges in holes about a foot apart, and covered over. Within ten days the green shoots begin to appear above the soil accompanied by weeds. Work now begins in serious earnest for the cotton planter and his hands. The first thing to be done is to thin out the plants, so that only one plant remains in every space of one foot in each row. When this is done, the weeds claim attention, and during the next month require assiduous hoeing or ploughing between the ridges to keep them down. If the weeding has been done systematically and thoroughly, the land may be rested at the beginning of the fourth month after sowing, and on to the time of ripening. This is to allow the soil to settle firmly round the roots and nourish the plants. Plants that show a tendency to grow much wood should be rigorously topped, to spare as much sap as possible for the fruit. In the fourth month the flowers begin to appear, and cover the fields with a sheen of gold and green. As the blossoms fade the bolls or pods begin to grow, and gradually swell. When the pods are ripe they burst, and from the capsules spring the white tresses of the cotton fibre.

Few sights are more wonderful than a cotton field when the fibre shows. The land wears a fleece of dappled white, the stems and foliage intensifying by contrast the dazzling purity of the wool, like the crowded mass of a million sheep miraculously washed. But the picture quickly dissolves, for the autumn winds are sharpening, and the pickers must work swiftly to harvest the crop.

Picking. Much ingenuity has been expended in devising mechanical cotton-pickers; but the difficulties to be overcome are subtle and baffling. The bolls grow at all angles on the plants, and the fibres stick firmly in the bolls. For a long time to come, we fear, the application of machinery to gathering cotton will be limited. A new cotton-picking machine [3-4], invented by Mr. George A. Lowry, a native of Ireland, resident in Boston, U.S.A., was tried in America during November, 1904, and pronounced a success. This invention does not supersede the cotton-picker, but facilitates his work, by an ingenious combination of power-driven hooks. The body of the machine is a gasoline engine with driving gear. At the four corners seats are placed for the pickers, and on both sides of the seats hang the picking-arms. These are ingenious contrivances, rods set in universal joints, along which run endless bands studded with hooks that, flying at the rate of 360 ft. per second, catch the lightest fibre.

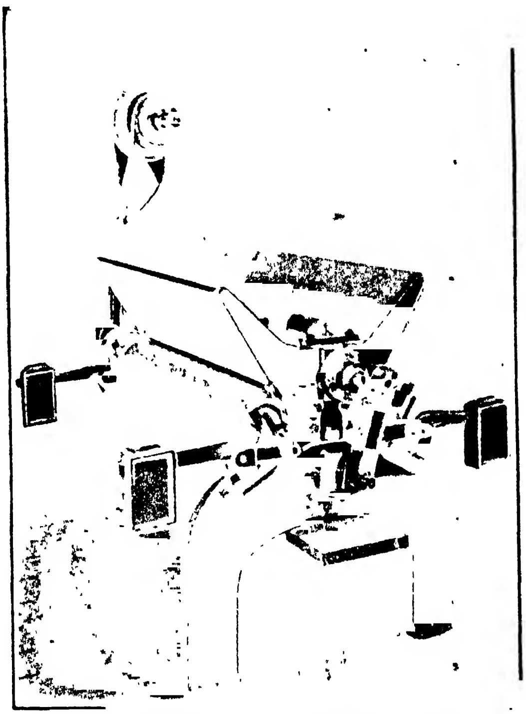
When the machine has arrived at the cotton row, the four pickers take their places, each having picking-arms on both sides of him. He directs the flying hooks on to the cotton bushes, and each little hook carries off a quantity of the fibre, being in turn deprived by a set of brushes, that sweep the cotton into suction tubes leading to the bags suspended from the overhead frame of the cotton-picker. The machine is worth the attention of men who are contemplating starting cotton-growing in those parts of the Empire where labour is difficult to procure. For the present, however, we must confine ourselves to describing methods actually in practice. Various districts have different methods of gathering. The old-fashioned way was for each picker to carry a basket slung on his or her neck, fill it and carry the cotton to the weighing-house near at hand. Others had large two-handled wicker baskets placed along the rows, a basket to each pair of pickers. The particular method adopted depends on purely local conditions, one of the most important of which is the custom of the natives who work.

The Planter's Problem. Here we meet with one of the most serious problems the cotton planter has to face—the labour problem. When a new industry is started anywhere, the difficulty of procuring labour is always considerable. Even in this crowded country, where nature yields nothing save to arduous labour, the early cotton manufacturers could not procure labour for the factories, and were compelled to resort to pauper children and train them up to the work. In the tropics food is easily procured, and the natives have few wants they cannot supply by very little exertion. To employ white labour is simply impossible. In one way and another the difficulty is, and shall be, got over. Contact with a higher civilisation creates in the native mind a desire for the things which can only be procured at the cost of labour. Long patience, tact, and perseverance, coupled with fair dealing, gather, in time, an ample supply of native workers round the British planter. The peace and security afforded by British rule have already encouraged the natives of tropical states to adopt a settled and industrial mode of life.

Ginning and Baling. Some large plantations have a central ginning house, situated at a point most convenient for all the fields, and employing steam-power. More common is the arrangement which attaches to every large field a gin-house. For a long time the planters of the United States cleaned cotton by hand, a process both tedious and costly. Wideawake as they were, it is wonderful that the planters of the west remained in ignorance of the *roller gin*,

or *churka*, used by the cotton planters of the East Indies from time out of mind. Simple as it is, the churka [5] is a most ingenious contrivance. The rollers thin to opposite ends, thus giving a transverse dragging motion. Each tuft of cotton contains within it a mass of seeds. To separate the seeds from the cotton is the work of the gin. Holding the cotton in one hand and feeding it to the rollers of the churka, the Indian turns the handle with his other hand. The rollers drag in the cotton and squeeze back the seeds, which drop on the inside while the freed cotton falls on the other side.

Left to their own devices, the Americans did not take long to invent a ginning apparatus. In 1793 Eli Whitney invented the saw gin. Though a rough and simple contrivance, the saw gin contained the idea which has since been developed into modern machines of high efficiency. The machine consisted of two parts, a wire hopper and a roller. On the hopper the wires were set close together, so that the cotton seeds could not pass through; on the roller were wound a series of saw blades; the teeth of the saws, slightly hooked, were set between the bars of the hopper. When the cotton was fed in and the roller set going, it dragged the cotton through, leaving the seeds to fall to the bottom of the hopper.



6. THE DOUBLE-ROLLER OR MACARTHY GIN

Improving the Gin. For short-stapled cottons, the saw gin was an efficient seed-separator, but long-stapled cottons of fine quality, such as Sea-island, were torn and greatly reduced in value by the machine; but the planters saw the advantage of using machinery, and went in search of an appliance that would suit. The Indian churka might have answered the purpose admirably. The working of the roller-gin, however, though suitable to a land where time is cheap and wages low, was too slow for the planters of America. The saw gin, it seemed, must be improved, and it was—with results we have now to review.

Whitney's saw gin had several serious faults, the chief of which were the tendency of the saws to clog and the injury done to the fibre by the sharp drag of the saws. The first was

7. GINNED COTTON

partially remedied by a brush arrangement at the side of the roller, and the second was also modified by an adjustment of double cylinders. Another improvement of the saw gin was the attachment of a fan which helped to clear the cotton of dust while it passed through the gin.

Other inventors were quickly in the field, and a host of cotton gins, each advertised as better than every other, have been put at the disposal of the planter. We will look at a few of them and try to appreciate the merits of each, without making too much of any. The *Double-roller Gin* [6], sometimes called the *Macarthy*, was one of the earliest independent inventions designed to combine the merits of the saw-gin and the churka. On the top is a hopper beneath which run a pair of rollers, spirally grooved. Within the hopper knives are fixed, geared so as to press against the rollers, their pressure being regulated by a set of weights hanging outside the hopper. When the cotton is laid in the hopper and the gin is started, the rollers drag the cotton down, the knives press the fibres against the grooves of the rollers, the sharp edges effectually hindering the seeds from passing through and freeing the cotton from them. The seeds fall into the box below, and the cotton gathers in a heap under the end of the machine.

Other Varieties of Gin. The *Knife Roller Gin* is very similar in principle to the Macarthy Gin, with additions of some ingenuity. Leather-covered rollers revolve under the hopper against fixed knives named *doctors*. The characteristic feature of this gin is the cylinder fitted with spiral knives that run on the fibres as they are drawn down by the rollers and fixed knives, carrying off the seeds, and clearing them of fibre. The spiral movement is here transferred from the rollers to the cylindrical knives, and it is claimed that a higher rate of speed is promoted thereby; but upon that we pronounce no opinion.

Different from the two already described is the *Lock-jaw Gin*. Above the roller is a movable blade, and in front are beaters. As the cotton is drawn forward by the roller, the beaters strike upon it, and the knife moves down on the roller, forcing the beaters to denude the fibre of seeds completely. We have been much struck by this gin, because it removes a large amount of dust and adhering vegetable matter as well as the seeds. On the other hand, rival models are equally admired by many practical men.

These three machines are typical representatives of the many models of roller gins at present on the market. Whatever may be the model chosen, it ought to possess three special qualities. First, it must thoroughly search the fibre and remove the seeds; second, swiftness of action is most desirable; third, the gin must not injure the fibre. If, in addition to these indispensable qualifications, the gin has the power to clean the cotton or improve the fibres, so much the better.

Baling. When the cotton issues from the gin, it is opened out [7], a pound occupying a considerable space. This openness would be a desirable quality if the cotton mills were only a few yards from the cotton fields. At present, however, the planter grows cotton for a distant market, the great bulk of it requiring to be shipped. Loose fibre cannot be shipped. The pressed bale is the only alternative, and it has been adopted. When machinery was not so readily available as now the feet of the field hands were employed; but that method of pressing has long been discarded in favour of the hydraulic press. Another point to be noted is that the cotton manufacturer has always liked his bales to be of uniform weight. Weight has to be considered in calculations of cotton manufacture, and it is well to begin at the beginning. Accordingly, the presses now used by the leading planters in pressing cotton are also weighing machines. Under the ram of the press is a box, and into this the elevators pour the cotton, which is pressed down as it comes in. When the proper weight has passed into the box, a lever is freed, and down comes the whole pressure of the ram, squeezing the mass into a solid lump, oblong in shape, with square sides. In such shape cotton can be packed into small space in the hold of a ship or on railway trucks.

The hydraulic press with which we are most familiar is one of many; but the principle and object of all baling presses are the same. The bales are covered with coarse canvas, sewn up and hooped. In this condition the cotton is ready for shipment.

To be continued

THE SPIRIT OF THE WORLD

Economising Time and Money. The Atmosphere of a Foreign Land. Attractions and Advantages of many Countries. Guides

By J. A. HAMMERTON and WM. DURBAN, B.A.

HUMAN nature is proverbially gifted with the capacity of adaptation to almost any set of circumstances and conditions which may be encountered in life. But for this natural faculty very much of life would be almost unendurable. Those who possess it in the highest measure make the happiest travellers.. For it is impossible to gain either enjoyment or benefit from travel without some degree of assimilation. We must, in order to appreciate the peculiar features of a country, or the special characteristics of a strange people, place ourselves in the mental attitude of appreciation. Psychology is national as well as individual, and there is in any community a collective soul that invites our study. The "spirit" of a country is determined by multitudinous complex factors, such as climate, racial affinity, history, heredity, struggles in the past (whether for independence or for subsistence, or in industrial and commercial competition), intellectual proclivities, geographical position and religious customs.

"Getting into the Atmosphere." The sympathetic traveller unconsciously absorbs much of the spirit of the new country that he enters, and hence the delight of travel. The sense of novelty is constantly renewed as the wanderer moves along the pathway of an extended journey. He marks the alertness of the Americans, the acumen of the Germans, the vivacity of the French, the serenity of the Swiss, the dignity of the Spaniards, the elasticity of the Italians, the animation of the Austrians, the courtesy of the Danes, the simplicity of the Scandinavians, the sturdiness of the Finns, the geniality of the Russians, the manliness of the Turks, the acuteness of the Greeks, the light-heartedness of the Roumanians, the reserve of the Arabs, etc. And he finds, on studying the causes which produce the demeanour of any particular people, that these causes are as interesting as the resultant effect which is attracting his interested attention. It is thus that travel contributes to our education.

The Uses of the Guide. If the traveller is willing to make the most of the things which range themselves under his observation, he can go nowhere without great gain. The true traveller does not practise the flippant "touch and go" system which implies the vulgar "doing" of districts for the sake of vaunting that they have been "done." This wretched fashion makes the very least of everything, and is a profane waste of time, money, and opportunity. One of the main recommendations of a foreign tour is that it develops the finest perceptive faculties, cultivates a variety of tastes, and impresses knowledge indelibly on the mind, by presenting to us countless concrete facts, and bringing us into actual contact with the world's realities.

As little time as possible should be spent in mere lounging in hotels and in pensions, in concert-halls and theatres, for when the tourist is on the wing there are usually endless peculiar local objects claiming his interest, and mere amusement may almost always just as easily be found in resorts in our own country. For any who are physically weak, and are seeking to recuperate, the most expedient method is to select some one of the many lovely spots on the Continent as a centre, and to indulge in easy little excursions round about it. Intimate acquaintance is thus cultivated with charming native village life and its novel conditions.

How Time and Money are Saved. Those who for the first time visit a city of any magnitude beyond the familiar range of Continental travel, more especially if they have but a short time to spend in viewing its sights, should make a point of sacrificing their independence and engaging a skilled guide. Especially should they do this if they have no knowledge whatever of the language. A guide-book is of course indispensable, but it is not always adequate for the purpose of the visitor who is an entire stranger in a great foreign city. An English-speaking "cicerone" is usually to be found hanging about any first-rate hotel in any one of the most populous cities. In Athens are several most intelligent men who will undertake for a remarkably reasonable charge, as we ourselves have tested, to pilot the traveller through any part of Greece, and will so manage the tour as to save the funds of those employing them to an extraordinary extent, simply because they perfectly "know the ropes." The visitor who attempts to find his own way about such places as Constantinople, Smyrna, Ephesus, Nijni Novgorod, Moscow, Warsaw, Kieff, Syracuse, on his initial visit, will either lose himself or else lose the chance of seeing many of the very objects most worthy of his inspection. A competent guide magnifies and multiplies the interest in many directions. He saves time and he has a thousand things to tell that are worth hearing.

The Needless Risk of Life. Perhaps the acme of folly is that of which inexperienced tourists are guilty if they venture to explore dangerous mountain districts alone. Life should surely be counted too precious to be thus recklessly risked. Glaciers, with their beautifully terrible crevasses, avalanches, snowfields, chasms, precipices, mists, and falling stones, are not to be trifled with. Even the

most adventurous spirits should take every reasonable precaution.

Arranging for Guides. In traversing certain of the districts in Calabria, and in Sicily, and in Greece, which were not many years since the favourite haunts of brigands, we have been repeatedly told how men employed by unwary foreigners would lead them actually into the traps laid for them. Even now there are attractive regions where it would be folly to make use of the proffered services of any but a registered guide. Apart altogether from the question of danger, the tourist may be subjected to a variety of tricks. He may find the men leading him ignorant of the way. We have known persistent attempts made in the middle of a mountain pass to extort from the traveller double the amount of the fee agreed on, under the pretext that the weather was not agreeable, or that the baggage being carried on the shoulders of the guide was extra heavy. Above all, it is vitally necessary beforehand to have a definite agreement, in presence of the hotel landlord or the Mayor of the Commune, as to terms. This is easy enough, because almost universally in places of familiar resort there is a printed Government tariff regulating every particular. Nothing is more useful and nothing is more essential. Never employ any guide who is not authorised or recommended. Many an unfortunate and unsuspecting tourist has been victimised by engaging the services of some volunteer in the Swiss or Italian Alps not on the list of the "authorised guides." The Italian Government is specially solicitous concerning the dealings of native conductors and "ciceroni." In every little town may be found young men and lads wearing on their caps the magic words which are the envy of other youngsters, "Guida Autorizzàta."

Without Guides. Nearly all experienced travellers can recall sad illustrations of the principle that we are emphasising—that, under certain circumstances and in certain localities, the services of an expert guide are indispensable to safety. We happened, during a visit to Norway, to hear, as we slowly proceeded through one of the loveliest mountain regions of the interior, rumours that young Mr. F., son of a noted English photographer, who was taking photographs of the most beautiful points of view for the firm, had fallen into a cataract. At every stopping place we found that this tragedy was the chief theme among the people, and when we reached the spot where the accident had happened, we could not help deeply regretting that the natural impetuosity of youth, risking peril under the temptation so often yielded to by adventurous young spirits, should have robbed a fine young fellow of his life. And we happened to be in Constantinople when the chief talk there was about the mysterious disappearance of young Mr. M., son of a well-known London publisher, on the slopes of the Asiatic Olympus, near Brusa. When we crossed over into Asia Minor, and were in the district, we learned what particulars could be gathered, although the mystery was never solved, and the young Englishman was never again seen or heard of. He was ascending Olympus with a friend and a guide. The three had scaled one of the two peaks of the beautiful mountain and had descended. Mr. M. resolved to go up the other horn, and in his eagerness outstripped the guide and his companion. He vanished round some rocks at the foot of the peak, and unaccountably disappeared. It was supposed that some of the shepherds, many of whom occasionally act as brigands, had instantly kidnapped him, and that afterwards, when search was being made, under the auspices of both Turkish and British authorities, they made away with him in fear of the punishment they would have incurred. The lesson is a serious one. A guide should be followed, not led.

Not so Easy as it Looks. Nothing can be more misleading than a certain inference that the reader may easily draw by reading light and entertaining books of travel or articles struck off by expert magazine writers on travel. The idea is apt to steal over the mind while perusing some such specimens of very fascinating literature that many of the most risky feats are in reality devoid of all danger. For instance, many of Mark Twain's delightful sketches would make it appear that it would be simple fun, safely enjoyed, to wander anywhere and anyhow, at any hour of the day or the night, in great foreign cities or remote corners of distant lands. No notion could be more delusive. Even the most intelligent people frequently find themselves in a most distressing predicament through wandering off the beaten track alone in places where they are entirely strange to the country, the people and the language. There lies before us at this moment in the new issue of a magazine a very readable article entitled "Up the Matterhorn without Guides." It makes very pretty reading indeed, and it is true that the Matterhorn has been rendered much easier to scale than it formerly was, but there is not a sentence in this article to warn the inexperienced against the peril of attempting to emulate the feat described. It sounds ludicrously easy. The spirit of adventure is different from the spirit of ignorant recklessness.

The Little Things of Great Interest. One of the best modes of enjoying travel is to cultivate the art of noting the trivialities that make up by far the greater part of the details of life amongst any people. The talk of many tourists who attempt to describe what they have seen is altogether hackneyed and excessively tiresome, simply because they confine their sight-seeing to what is attended to by the overwhelming majority and has been described countless times before.

Take as an instance the fascinating city of Leipzig. Here we may study the very concentrated essence of the Teutonic spirit. Dear old Leipzig is Germany in epitome. Yet we know many people who have visited it time and again and have only seen it most superficially. They have never risen early in the morning to see for two hours before breakfast the wonderful popular life—the real life of the workers of

all grades in one of the busiest cities of Europe —which when once seen can never be forgotten. The dogs and the women dragging the little milk carts, the market "Frauen" pushing their quaint vehicles of vegetables and fruit along, the great wagons full of big rolls of fragrant, finely-dressed leather from the big factories, the troops of men and working girls hurrying along, the vendors of strange sorts of sausages, cakes, and other dietetic commodities unfamiliar to us, and, above all, the boys and girls in thousands passing to school, all of each sex alike beautifully dressed, and carrying their strapped knapsacks with books and food for the day—these are a few of the typical sights peculiar to the early hours of the day. Afterwards the mass of tourists are alert; but they have missed the spirit of the city. And we recall now, after a good many years, what an interesting glimpse we had once of the life of Lorient, "the French Portsmouth," where we arrived by road early one morning as the workers were streaming from the suburbs into the town. We caught more of the spirit of the place in that brief passage than a day spent in the conventional saunter about the main streets of the town would have afforded.

The Atmosphere of a Place. When Henry Ward Beecher was travelling, either in this country or on the Continent, he entered just in this style into the temperamental condition of every locality that he visited. He was on summer mornings always up very early that he might watch the common people in their proceedings. The "atmosphere" of a country is composed of the elements derived from the physical geography, the history, and the popular mind together. The nature of the country is formative of the habits of the inhabitants, and both should be studied if the profit and enjoyment are to be complete.

Copenhagen is a city of enchantment, but we know Denmark more truly if we not only see the capital, but wander awhile among the country people who are astonishing the world by their farming and dairy achievements.

The tourist will not know his New York very intimately if he merely rides up and down Broadway or Fifth Avenue, gazes at the skyscrapers, takes the trolley-car over to Brooklyn, sees a few theatres and churches, and indeed rides everywhere. He should wander on foot in China Town, in the great Ghetto district, walk about Brooklyn to see its incomparable, boulevarded, maple-lined avenues running for miles, take the steamer to Glen Island, survey the Bowery, linger in the wonderful Aquarium, peep into some of the congested foreign colonies along the sides of East River, feed in some of the common restaurants, and make some of the people understand that he really wants to learn something. They will tell him curious facts, and show him strange things, and he will understand the atmosphere, social, industrial, commercial, and political, of the vast city on Manhattan Island, and its huge overflowing annexes.

Our advice applies of course to travel anywhere. Where time is short, much may be seen in cursory passage and fugitive glance, if the mind is keen on receiving impressions, but where the traveller can halt for a longer stay, he must penetrate beneath the surface if he would learn many things best worth knowing.

Letters of Introduction. Those who take with them letters of introduction to personages resident in places to be visited are truly wise. How often have we ourselves proved the expediency of thus preparing for the best line of action. For example, when we landed at Smyrna on one occasion, we went promptly to a Greek gentleman settled in that city who carries on an immense fruit-packing industry, and owns many vineyards and orchards in Asia Minor.

Though to him we were total strangers, our letters to him from mutual friends in England won his kind heart instantly, and for a whole week he was at our disposal as much as we were pleased to avail ourselves of his boundless kindness. We remember that this gentleman was both amused and alarmed at the idea we had formed, amongst our other schemes, of taking some little excursions into the hinterland of Smyrna, which, with its mountains, looked so tempting. He drove us about the environs in his carriage, but explained that one of his most intimate friends had a few years previously, in that very region we wanted to penetrate, been captured by the notorious robbers of the interior, who had sent in to his friends for a ransom, which, heavy though it was, had to be paid in order to save the life of the citizen. Our Greek patron himself had never dared to venture amongst the lovely mountains yonder. But he made us wonderfully familiar in a few days with the chief city of Asia Minor, and thus we proved once more the advantage of seeking help in such fashion. He took care that we should really know the city where he lived and where he was one of the most influential citizens.

In European travel it is well to be a member of such an organisation as the Touring Club de France (5s. annual subscription), whose "delegates" are scattered all over Europe, and are always at the service of their fellow members, as we had proved on many occasions while travelling in out-of-the-way parts of France and Germany. As an instance of the value of this splendid organisation, we might mention that, desiring to make a cycle tour through the most beautiful and historic parts of Alsace and Lorraine the other year, we wrote for information to the delegate of the club at Saverne and that gentleman furnished us with several itineraries and the most elaborate, but extremely useful particulars of the roads, hotels, and so forth, inviting us to call upon him when we reached his own district, and placing himself entirely at our service; an offer we were delighted to accept in the true spirit of camaraderie. In many other towns the delegates of the Touring Club have proved equally obliging.

When to Visit Foreign Lands. The difference in the same country at different times of the year is in many cases astonishing. There are lands which it is the height of folly to visit at certain times of the year, while they are a

other seasons supremely attractive. Attention should by all means be paid to this point. A popular English minister of religion some years ago took a holiday of a few months, intending to pay a prolonged visit to the United States. Unfortunately he went just at the hottest time of the year. The consequence was disastrous. A latent heart trouble, which had been entirely unsuspected, quickly developed in the intense heat, and the preacher died in America. The "Indian summer," in late autumn, is the most delightful time of the whole year for travelling in the United States. The latter portion of springtide or earlier period of summer will be found almost as enjoyable. As to India, summer in the great plains is a purgatory, while winter is enchanting.

Climatic Conditions. Surely nothing is more important for the average traveller than the consideration of climatic conditions. For instance, we cannot imagine an Englishman enjoying the torrid conditions of Greece in the height of summer, when the whole land is a parched caldron. But in winter it is like a garden of the gods, and in spring the land is too beautiful, with its verdure and its flowers, for description.

October is a fine month for that country, as also for Turkey—European or Asiatic. The climate of Russia is glorious, and the "white nights" of the North are the joy of the traveller, although if he comes down south he will not conveniently bear the midsummer heat. A trip in Southern Russia is very enjoyable in September. This applies also to Austria and Hungary, to Servia, Bulgaria, and Roumania. As to Italy, that paradise in the Mediterranean has a strange variety of climates. Among the hill cities of the Apennines and in the charming resorts high up in the Italian Alps, and especially in Tyrol, we have revelled in every condition of comfort so far as the atmosphere was concerned during any part of summer. If we would find ideal summer joys we must succeed in our quest anywhere in Norway, Sweden, Finland, or Denmark. To Spain go in late autumn or early spring. Germany, Holland, Belgium, and France we may see with absolute pleasure at almost any season we like to choose, always remembering that the South of France and the whole Riviera are exceptions, for these delectable regions are semi-tropical in summer and swelter then in the breath of the sirocco, while in winter they call loudly for the invalid to patronise their health-giving resorts along a lovely coast bathed in delicious sunshine. Cyclists, however, should avoid July and August for long journeys in all of these countries. For nearly all the year Sicily is a dreamland of climatic luxury and of unearthly loveliness. And Capri is never either oppressive with the heat or repellent with cold.

Calculating on Local Conditions. We have alluded to the strange differences of climate that may prevail in contiguous districts. Any tourist may easily take advantage of these same differences. We remember how, when one summer, even though the season was growing late, the heat was intolerable in the region of the Italian Lakes. One day, in Brescia, we concluded that we would retreat out of the palpitating atmosphere to higher pleasure grounds. We took conveyance for Madonna di Campiglio, and there, in an elevated centre, where exquisite valleys meet and mountains soar up like Adamello and Spinale, with cool glaciers and purling streams everywhere in view, we found life worth living day after day, for we had ascended just 5000 feet. Again, on another occasion, we had a very similar experience in Switzerland, making a hurried retreat from sweltering Geneva to the lovely valley of Chamonix, where the cool nights tempered the summer atmosphere delightfully. Thus, the tourist who chooses localities for a summer trip where he can make his programme elastic enough to accommodate himself to convenient and desirable conditions is apt to be happily rewarded.

The Features of Other Lands. The special characteristics of various countries must surely enter into the consideration of a would-be traveller. He may wish to regulate his choice by some of these. No country is without individuality all its own, and this must have its influence. No country is so accessible for us in England as France. But people on this side of the Channel are generally little aware of the richness of the neighbouring nation in its architectural gems. It is a land of superb cathedrals, which strangely escaped destruction during the Terror. And, of course, when we are thinking of cities reconstructed in the modern style of supreme beauty, the mind at once flies to Paris.

Italy is the world's unrivalled art-gallery, from the lakes of the North to the extreme point of Sicily in the South. The visitor who roams about its cities, whether in the Apennines or in the plains, may despair of exhausting the marvels that have accumulated from Etruscan days down to our own times. Greece is the very shrine of history, and a sojourn in Athens and Corinth, in Nauplia and Patras, will make any traveller feel that he had indeed added an invaluable course to his education. Germany is truly called "the brain of Europe," and it is at this moment more worthy of attention on the spot than ever, for there the country is being turned into a veritable laboratory of economic and industrial practice, working out the most advanced theories of the savants.

For glory of scenery, Switzerland is naturally peerless, but it is worth personal study as the home of the happiest community in the world. Holland and Belgium make any holiday delightful because of their perfect presentation of the quaintest charms of Mediævalism. Norway, with fjord and fjeld, brings us to the gateway of the Arctic, and is the finest European field for adventure and romance with the minimum of peril. Egypt is the casket of the hoariest antiquity.

And so each land has some pretension to particular merit, and each will amply reward a preferential choice that may happen to fall to it in the traveller's decision.

SHOPKEEPING

3

Continued from page 279

THE SCIENCE OF THE SHOP FRONT

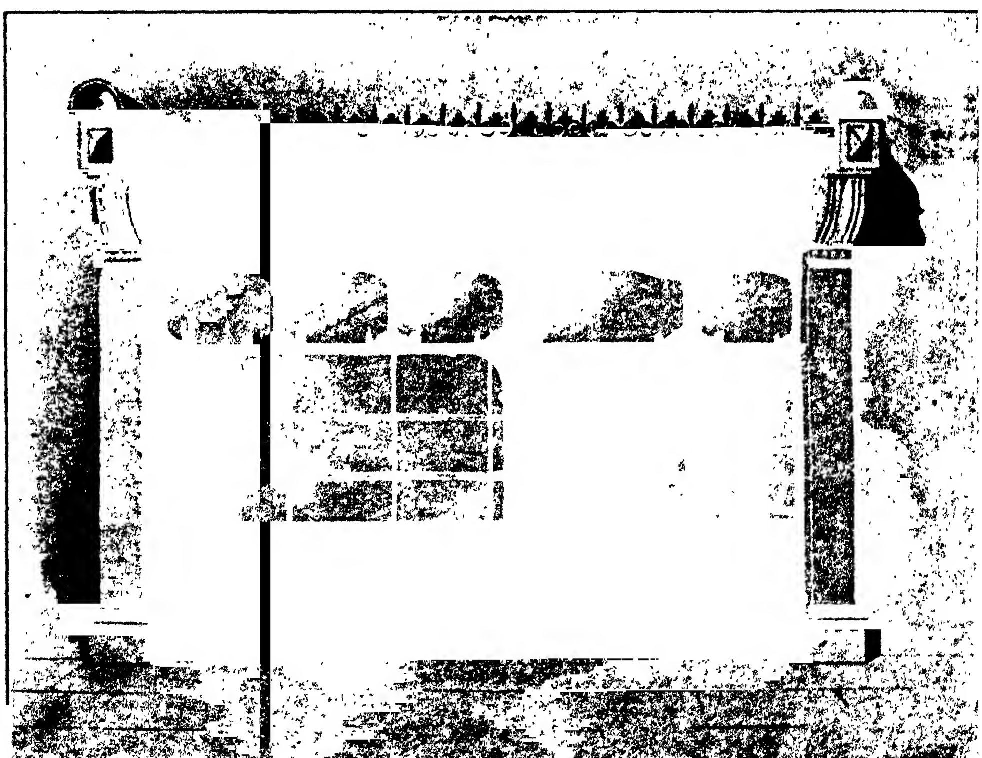
A Question of Vital Importance to all Shopkeepers. The Value of a Good Front, and the Considerations Affecting it

By W. B. ROBERTSON

The Scope of the Shop Window. The business man who neglects his shop window is as culpable as the soldier who allows his rifle to become foul or his sword rusty. The shop window is the chief medium through which an impression may be made on the public, the principal bait to draw fresh custom. George Chapman wrote, "Keep thy shop and thy shop will keep thee." We venture to make the statement a little narrower, and to offer as a sound business maxim: "Keep thy shop window attractive and thy shop will keep thee." Not that an attractive window display is the single essential to a successful business. It is, or may be made, nothing more than the most effective agency in drawing strangers to the counter. The quality of the wares and the manner of service must decide whether or not business will result.

In these days of twentieth century competition, when the ability of shopkeepers to provide articles of consumption, use and ornament is greatly in excess of the purchasing power of the public, the growth of any business must depend largely upon the success of its proprietors in attracting the customers of competing trade men. To look around us in mental survey and to consider those tradesmen whose operations have exhibited progressive increase in number and magnitude is to acknowledge that the successful men are those whose window displays are features of their business practice.

Analysis of the conditions which go to make a successful window display shows that they naturally divide themselves into two classes. First there is the shell of the window, the shop front, and, secondly, there is the contents and their arrangement. Many shopkeepers spend



1. AN ARTISTIC BUT INEXPENSIVE SHOP FRONT

a good deal of time and money on one or the other, but not on both. Their sins of omission in one department more than neutralise the work and value they have put into the other. In any street in any city in Great Britain it would be possible to find shop windows with expensive fronts and soiled or carelessly arranged contents. The effect is as incongruous as when a choice sample of the milliner's art surmounts a grimy face. This fault is much worse than that of a window with a poor shell and a tastefully-arranged interior. Excellence in both departments gives us the ideal—and the successful shop window.

The Shop Front. We would first give some attention to the shop front from both the artistic and utilitarian points of view. What a transformation in the shop fronts of our city streets the last generation has witnessed! The security of the shop was formerly thought to depend upon the solidity and the impermeability of the front. We had shops protected as were the hulls of Nelson's battleships—heavy iron-plate shutters and doors, bolts reaching from floor to ceiling. Now light takes the place of iron plates and bars. Windows with large expanse of glass, protected only by spidery grills through which the interior is visible even by night, are undoubtedly the most secure as well as the most attractive form of shop windows which the retailer can adopt.

The shop front should be in harmony with the class of trade in which the shopkeeper is engaged. The light and artistic front which we admire in a jeweller's shop—and which we also expect, though not in quite so pronounced a form—in a confectioner's or a draper's shop, would be out of place in a builder's, an ironmonger's, a butcher's, or an oil shop. The nature of the trade, whatever it may be, should find expression in the form of the front.

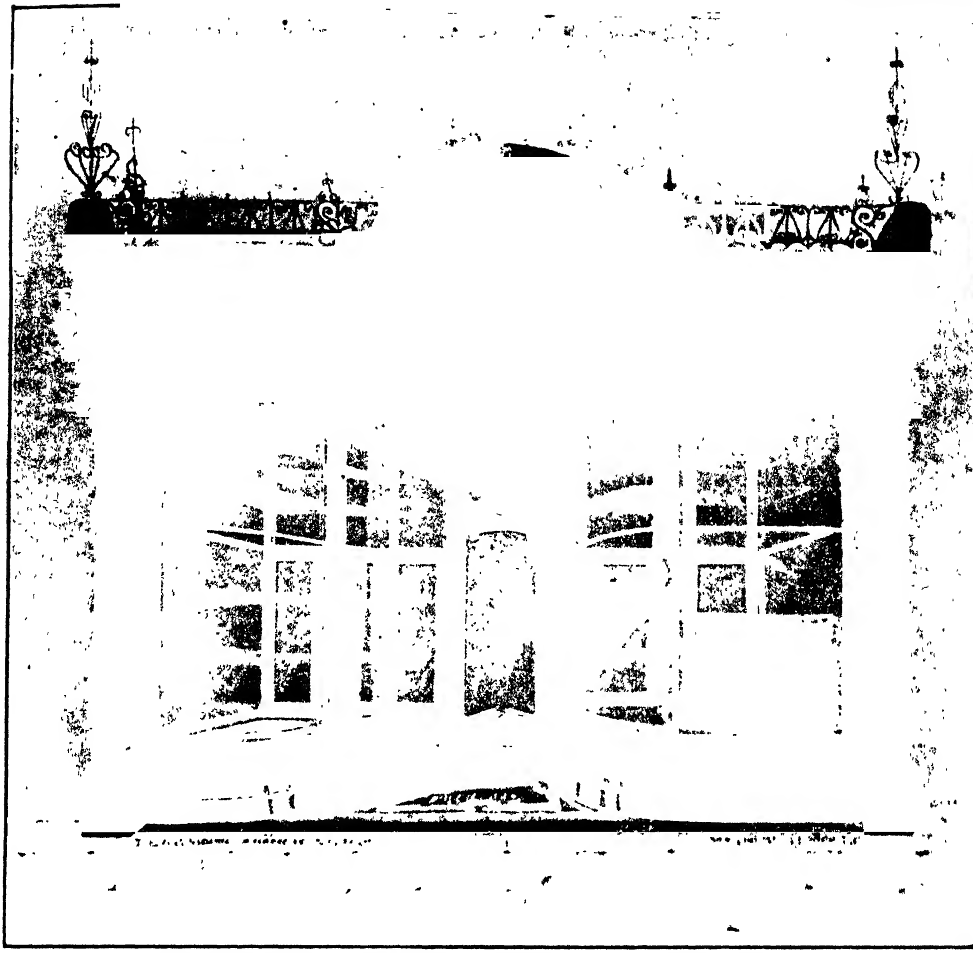
A Shop Front as in France. We know of no class of shop where the trade is advertised by the front so thoroughly as it is in the paint and oil shop of France and some other European countries. Almost invariably the entire front of the shop building is planned in radial segments in which all the colours of the spectroscope are depicted. The shops are masses of paint patches and indicate the nature of the business more plainly than the hues of Joseph's coat indicated the personality of the wearer. We have not observed that any English painter and colourman has copied the practice of his French fellow. The plan is so practical and so appropriate to the trade concerned that few people would find fault with it. It might be objected to from the æsthetic point of view, and we confess that sometimes there would be some reason in the objection. Frequently the primary and secondary tints chosen are rather strong to be pleasing, and we believe that the more general employment of neutral tones would serve the purpose as well without violating one's sense of colour harmony. But the practice of the French oil and colour shop is one which the British retailer might introduce in a modified form.

Counting the Cost. A shop front of some pretensions to elegance costs a little more money than a plain one. The higher cost is often the reason for the installation of the less attractive form. If consideration of the question be based upon true principles of business economy, it is well, and it may be that wisdom has been shown in selecting a common, cheap shop front. But the true principles of business economy are not always placed in the witness-box when adjudication is being made.

To help us to understand the expenses incurred by a special shop front, a prominent firm of London shop-fitters have supplied us with two designs which they have recently executed. One is for a baker and confectioner, and the other for a jeweller. The former [1] was executed in mahogany. The space available was 18 ft. wide by 11 ft. high to the bottom of the facia. The cost of the front only, made, fitted into position, glazed, and finished, was £90. The disbursement of such a sum for such a purpose should be decided by the question of prospective profit.

Less than a Shilling a Week. It may be assumed that a common shop front would cost not less than half of this sum, so that a front of the design we illustrate would entail an increase of £45 in expenditure. That is capital expenditure, and the interest on the amount at 5 per cent. per annum would be 45*s.* per annum, or just under 10½*d.* a week. The baker or other tradesman to whom the question presents itself, and whose establishment would be rendered more attractive by a specially-designed and executed front, has to consider whether or not the difference is worth, as a paying investment, the sum of 10½*d.* per week. We think that, put in this direct and practical form, the answer would seldom be in the negative. The internal fittings of the shop window we illustrate cost about £35. We did not include these in the simple financial problem just presented, and rightly so. These internal fittings would have been necessary, or at least desirable, in any event. They included air-tight glass show cases, glass shelves, brass standards and brackets, and tiled surround. In this particular case their expense was more than repaid by the preservation of the confectionery through being protected from atmospheric influence and dust.

Importance of the Window Frame. When the expenditure of a few pounds extra in the erection of a shop is a barrier to the installation of both a good front and good internal fittings, it is advisable to decide upon the former in the first instance, leaving the latter until such time as funds may warrant the disbursement. It is a small matter to replace internal fittings, whereas to tear out a front and replace it with another is a much more serious and costly business. In 2 is illustrated another shop front of special design, which we reproduce for two reasons. It shows a front of greater pretensions than that to which we have just given attention, and incidentally it teaches how available window space may be made apparently much wider by a simple trick of design. In this par-



2. AN ARTISTIC AND EFFECTIVE DESIGN FOR A NARROW FRONTAGE

ticular case the shop was for a watchmaker and jeweller. The space to be filled was only 16 ft. wide by 11 ft. high to the bottom of the facia. The work was carried out in mahogany, and the total cost, including all the special air-tight window fittings most suitable for the trade, was between £250 and £300. Assuming the higher figure as the price, computation upon the basis already indicated shows that the interest on the capital sunk would be less than one shilling a day. A jeweller considering plans for a shop would have to consider if a front, window, and window cases of the class illustrated would be worth a shilling a day as a business investment, and in any town except the very smallest, we fancy that here, again, there would not be much doubt of the decision.

The space available in the case before us was, as already stated, exceedingly narrow, only 16 ft. between the pilasters. The manner in which the utmost has been made of this space deserves attention. The circle given to the glass—on one side of the door a convex circle, and on the other a concave and convex—made the window front much wider than it would have been had the more common design been adopted. Had both sides circled outwards, spectators would have been likely to block the doorway to a much greater extent than with the convex and concave form shown in the design.

Points for and against the circled glass in the shop window are that it is much stronger than ordinary flat rolled plate, that it costs much more, and that it is often extremely difficult or impossible to replace a broken window speedily. When circled windows are fitted, it is always advisable to purchase and store duplicate panes, so that immediate replacement is possible in the event of breakage.

Window Cases. The nature of the window interior depends so much upon the trade and the goods to be shown that a general consideration cannot descend into minute detail. Any arrangement should never lose sight of the frequent need of withdrawing and replacing exposed articles. The difficulty of extracting

individual articles from the window sometimes causes retailers to establish a rule that no articles be sold therefrom. This is always bad. Refusal to sell from the window breeds in the mind of the would-be purchaser a suspicion that the goods sold over the counter are not of the same quality as the window samples. The shopkeeper who values a reputation for frank and straight dealing should make a profession of willingness to withdraw any article from the window upon request, and to enable him to do so he should have his window fittings arranged and his windows dressed so as to permit him to do so with the least possible inconvenience.

Air-tight glass cases are usual in the shop windows of many trades. They are valuable in preserving the goods shown from deterioration by atmospheric influence, but they have their limitations. If they must be opened very frequently they are of little practical service. Every time the doors swing back the cases become part of the shop and any fog or humidity which may permeate the atmosphere finds its way to the merchandise. Therefore, while air-tight cases are always desirable for delicate or tarnishable goods, their full value is secured only by refraining from opening them. This looks like a contradiction to what we have just said, and it is so. The shopkeeper must sometimes choose between refusing to sell from the window and having his window stock preserved untarnished.

It may be possible to mitigate the bad effects of opening a large window case by having the window partitioned into separate compartments individually air-tight. This is possible, for instance, in showing electro plate, and sometimes it is well worth the extra initial cost.

The Value of Mirrors. The value of reflection by mirrors in window displays is not appreciated as it ought to be. When a window is narrow and deep, the effect which one or more mirrors can lend is a great acquisition. In such circumstances the introduction of the mirror is most desirable, and there is no window which could not be made much more impressive if mirrors were made permanent or temporary features of the window displays. The mirror is most effective in a divided corner window. Placed at an angle in the window it catches the eye of the passenger and the window or the half of the window is made to appear double its actual size. Where mirrors are used, a flat scheme of window dressing should be adopted. If the arrangement be high in the front the mirror is robbed of its opportunity to do its full duty. A mirror placed so that passengers may see their own reflection usually causes many passers-by to stand and gaze. "Vanity of vanities, all is vanity, saith the preacher," and the preacher knew what he was talking about.

The mirror has an attraction not for the fair sex only. We have stood for fifteen minutes near a London window which held a mirror in a prominent position. We counted the respective numbers of each sex whom the mirror arrested, and the proportion was seven ladies to ten men, notwithstanding that the lady promenaders far outnumbered the men. We have seen a mirror of a special kind used to good purpose in a barber's window. It was a concave mirror, and therefore magnified. Placed close to the front glass of the window, it impressed the man whose habit was to shave every second day with the desirability of doubling the frequency of the operation, and it persuaded the man who had developed the practice of being his own barber that the task was one he performed badly The barber took a larger shop in a few months.

The Value of Light. It is common, in the shopping thoroughfares of our large towns, to see one shop stand out conspicuous among its fellows by the blaze of light which issues from its windows. The proprietor appreciates the value of light as a business agent. Indulgence in advertisement by light is expensive, but, judiciously used, it is remunerative. Sometimes the facia of the shop is surmounted by a profusion of gas jets. This is not a practice to be commended. It is extravagant, unremunerative, and foolish. The light should be focussed upon the goods displayed in the windows, and not sent out purposeless into the night. Perhaps the most conspicuous object lessons in the value of window lights are the shop windows of the vendors of imitation diamond jewellery, which are, at the moment of writing, finding an apparently lucrative field of enterprise in the large towns in England. The lights in these are usually incandescent electric, and they are generally numerous and concealed from the direct observation of the window-gazer. If they are aided by revolving pedestals covered with black or blue velvet, and mounted with paste wares, the sparkle emitted from the tiny polyhedrons of glass is fascinating. The public does not wait to consider what gives the effect, and is often induced to spend money upon such ornaments in the belief that no one will detect their falseness under ordinary conditions.

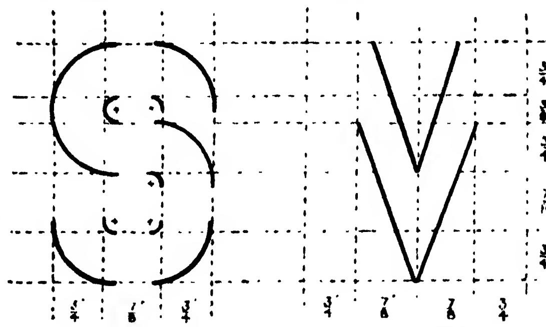
Electric Light. Many lighting mediums lie at the choice of the shopkeeper. The electric light has a great deal to recommend it. The electric arc light, however, should never be used. It is concentrated in one point or in very few points, and therefore throws shadows which should be avoided. Incandescent electric lamps are much better. They may be diffused throughout the window, hidden in any corner and arranged so that no shadows are cast. They do not throw off the products of combustion or the great heat of gas jets or incandescent mantles, and thus do not exercise the deteriorating influence which gas flame does upon almost every class of exposed merchandise. The objection to electric light is its high cost.

The disadvantages attending the burning of gas in a window are sometimes averted by having pavement lights—*i.e.* lamps suspended from above the window and throwing illumination into the window. These should be adopted only when the window is high. In any case, they are apt to throw the shadow of the window-gazer upon the contents of the window.

Taking into consideration every class and

method of application of window-lighting systems, that employing incandescent electric lamps is for every reason the best, and should be adopted wherever available if cost be not an insuperable barrier. Not the least of its advantages is that lamp holders may be placed in any position.

Window Steaming. How to cure window steaming is a problem that has exercised the wits of many shopkeepers, architects, and heating and lighting experts. The sovereign remedy, acceptable from every point of view, has yet to be found. Nothing is more objectionable than condensation on the shop window pane. It is caused by the difference between the external and the internal atmospheric temperature. The only thorough method of obviating it is by a system of ventilation, allowing the external air to circulate into the window, but the objection to this is that dust also penetrates, soiling the exposed goods and filling the window with deposit of extraneous matter. Several preparations, mostly of a glycerin nature, have been offered from time to time, but they are at best only partially successful. A remedial measure, efficient but expensive, is used in many large shops. A Bunsen burner, or several of them, are kept burning at the bottom of the window near the glass, and the steam of hot air which they send up close to the glass prevents the condensation.



3. HOW TO CUT OUT WINDOW LETTERS

Window-pane Legends. The introduction of the enamelled letter introduced a new feature into the shop windows and for a time the enamelled letter legend on the shop window-panes was painfully in evidence. Too often the cement which had been used to cause the letters to adhere had failed in its duty, and the result of dropped letters was often ludicrous and always unsightly. Improvement has been made in the cement used or in the method of its application, for we do not now see the mutilated words that used to constitute a guessing competition as to the dropped letters in every street. A letter with small diamonds or circles of coloured glass was recently introduced to the notice of shopkeepers. Its value lies in the fact that the light shines from the window through the letters in the evening. From this point of view the new style of letter may be acceptable, although in daylight the plain white letter looks better. But plain and ornamentally glazed letters should never be introduced into the same sign or word, although we have frequently seen it done.

The disadvantage of permanent window letters is that seasons goods cannot well be advertised by their agency. Sometimes a simple but inexpensive expedient is adopted to overcome this disadvantage. A little skill, experience, and ability to use a compass and square will enable anyone to cut from white paper letters perfect in form which may be attached with mucilage to the inside of the window, and which will deceive any casual observer into the belief that they are enamelled letters. Any smart assistant may easily acquire the method of cutting these letters. The accompanying sketch of two letters [3] will show the mode of marking off for cutting. It may be well, after a complete set of letters has been cut, to have duplicates made in zinc to serve as models for any that may be required subsequently, and thereby save the labour of marking off again. Great care ought to be taken to fix the letters straight on the window. Few things look worse than lack of proportion or misplacement of the letters, and they should be removed with the passing of the season, as to advertise an article out of season is foolish.

The Sign-board. The trading name and the nature of the business ought always to be displayed in plain bold letters above every shop front. Prominence is no excuse for neglect of this requirement. How often have we seen shops with the plain legend "Smith & Co.," or whatever the firm's style might be. Smith & Co. might sell watches, or sausages, or any other merchandise for all that the shop exterior indicates.

Plain Roman letters, or one of their modifications, where art has not interfered with legibility, should alone be adopted. Look down the shop signs in any village street and one may see written large what sort of a man the village painter is. He usually affects the style of letter he can paint most easily, and it is often a hideous thing of blobs and fish-tails that attempt to hide much disproportion.

When the shopkeeper is not quite steady in his orthography and the painter even worse in this respect some marvellous signs are often the result. The particular form of originality usually taken in such a case is in the profuse use of the apostrophe. We have *café* written *caf'e*, and every plural noun rendered in a possessive form. The punctuation of the sign is often bad. A full stop should attend all abbreviations, and should be placed at the end of the sign, but there should be none between the two words in such a name as John Smith. Different varieties of lettering should not be permitted upon a window or shop sign. Uniformity shows good taste.

THE RELATIONS OF THE ELEMENTS

The Periodic Law: its Meaning and Power of Prophecy. Are the Elements Truly Elementary? The Atom

By Dr. C. W. SALEEBY

A Brief Recapitulation. In the first half of the second lesson, as the reader will remember, reference was made to the future of chemistry in various practical and theoretical directions—a subject which naturally came up for consideration after the historical study of the first lesson. Even in those introductory parts of our subject it was necessary to speak frequently of elements—especially the discovery of new elements in the early days and also in recent times. Thereafter it was necessary to come to somewhat closer terms with the idea contained in the word elements: and reference has been made to the fact that the *periodic law* has already forced chemists to the conclusion that the elements are related, but that we cannot accept the simple view that the atoms of all the other elements are compounded of atoms of hydrogen. Thereafter reference was made to some of the principal elements, including those that make up a large part of the earth's crust, and also to the metals, which are dealt with in the special course METALLURGY.

We must now take up seriously the matters already referred to—the relations of the elements and the periodic law. We have by now had sufficient illustrations of the general proposition with which we started—that matter is of different kinds. We have seen that some of these kinds present obvious differences, while others are hard to detect from among their neighbours. We have seen that some of these kinds occur in large quantities in the *free state*—that is to say, not compounded with each other. We have also seen that some of these kinds are very abundant, whilst others are exceedingly rare, and we have made some reference to that group of kinds, long thought to be specially distinctive, which are known as the metals. And now our first concern must be that statement of the relations of the elements to one another which is known as the *Periodic Law*, or the Law of Mendeleef.

The Periodic Law. Ever since men began to arrange the different kinds of matter into groups or tables of elements, they have suspected that there exists some kind of a relation between one element and another, a relation none the less certain because it was impossible to say exactly in what it consisted. Reference has already been made to the suggestion, based on the relations of the atomic weights, that all the other elements are simply compounds of hydrogen. That, however, could not be accepted; nevertheless the study of the various atomic weights led chemists to the conviction that there must be some relation between the elements, even though it might not be so simple as had been suggested. Then, again, it was observed that from the various elements there could be picked out little groups of substances which resembled one another—for instance, Chlorine, Bromine, and Iodine; or Calcium, Strontium and Barium. The members of these groups resemble one another in singular degree, but this in itself was not sufficient to excite much comment. The point is that in these and in other cases, if we add together the atomic weights of the first and the last members of the trio and then divide the result by two, we obtain almost exactly the figure corresponding to the atomic weight of the intermediate member of the trio. This suggested that in each trio there was a sort of regular stepping forward in the complexity of the atom from the lightest member to the heaviest. So far there was merely probability and suspicion in favour of the view that in reality there is only one element; but a great advance was shortly to be made.

The Work of Mendeleef. Omitting the names and the contributions of lesser men, we may pass at once to the great discovery of Mendeleef, which will make his name immortal. This great student of nature, still alive when these words are written, is by far the greatest of all chemists yet produced by Russia. He was born 1834 at Tobolsk, in Siberia, and was the youngest of a family of seventeen. In 1864, when he was thirty, he became professor of chemistry in the University of St. Petersburg, and has occupied that chair ever since. We may ignore Mendeleef's other work and may confine ourselves to his discovery of what he called the *Periodic Law*. We are about to consider the grounds upon which the assertion of this law is based; but meanwhile we may note the remarkable manner in which the law has been vindicated by means of its power of prophecy.

The reader will remember the instance of the manner in which the law of gravitation enabled astronomers to predict the existence of a planet hitherto unknown, in consequence of the disturbances in the movements of the planet Uranus: thus they were enabled to discover Neptune. Similarly Mendeleef illustrated the truth of his Periodic Law by stating that there were certain gaps in the list of the elements as stated by chemists in 1871. In that year he asserted that there must be three new elements which the chemists had not yet discovered. He actually ventured to give them names suggestive of their affinities, to state their atomic weights, to describe some of the properties of their compounds and the colours of their salts. He called these elements Eka-Boron, Eka-

Aluminium and Eka-Silicon, and within fifteen years the whole of his prophecy came true. One of his predicted elements was discovered in the year of the prophecy, another eight years later, and the third in 1886. They are now known as Gallium, Scandium and Germanium. Not content with this most amazing of successes, Mendeleef frequently dared to assert that the atomic weights of certain of the elements as usually asserted and accepted by chemists must be incorrect, because they did not "square" with his theory.

Laws and Facts. Now, before we note the result of this piece of apparent presumption, let us permit ourselves a digression to observe that nearly all of us resemble Mendeleef so far. We have got a theory with which some facts or other do not tally, and we reply with the Frenchman, "Tant pis pour les faits"—so much the worse for the facts. This is the spirit which, perhaps above all others, except, of course, the spirit of acceptance of authority, has interfered with the progress of Science; but it need hardly be pointed out that in Mendeleef's case there is a fundamental though not very obvious difference.

Mendeleef had inferred, from a large number of accepted facts, a certain law. That was, of course, a typical case of what is known as inductive or *à posteriori* reasoning, the typical method of Science. Then, having reasoned backwards from the facts to the law, Mendeleef was enabled to reason forwards from the law to new facts by a process of deduction or *à priori* reasoning; but the facts that he thus deduced did not answer to the facts that had been stated by chemists as the result of actual observation. He therefore requested chemists to set to work to make their observations over again. He said, in short, concerning elements, which perhaps he had never himself seen. "There was something wrong in the manner in which you weighed this substance; weigh it again and you will find its weight to be not 30 but 31." Well, the chemists set to work to obey orders and found that Mendeleef was right.

Scientific "Law." This is an instance, like the discovery of Neptune, of the legitimate use of the *à priori* method in science; but supposing the atomic weights had been found to be not what Mendeleef—assuming the truth of the Periodic Law—had asserted, then the law would have had to go. What we call a *law* in science is, in the first place, a generalisation from, or a generalised statement of, a number of facts; but when we call it a law, we assert that it will cover more facts than those we have actually observed. At any moment such a law must be upset if there arrives a fact with which it is incompatible. We may remember Huxley's joke as to Herbert Spencer's idea of a tragedy: "A deduction killed by a fact."

Some twenty years after the enunciation of the Periodic Law there was discovered a series of elements, beginning with Argon and including Helium, Krypton, Neon and Xenon, which seemed to have no place in the periodic system, and which—had this suspicion been confirmed—would have sufficed to have upset the Periodic Law, since any deduction may be killed by a fact. But when the atomic weights of these five new elements were ascertained, it was found that they fitted perfectly and in due sequence into the periodic system just as well as if the great discoverer had constructed his theory with reference to their existence.

Evidence for the Law. Let us now consider the nature of the evidence upon which Mendeleef based this now universally accepted statement of the Periodic Law. There were already known the facts concerning the trios which we have named, and also the fact that a great many of the atomic weights could be reckoned as whole numbers, thus implying a relatively simple relation to one another. It was an Englishman, John Newlands, who set Mendeleef in the right direction, by showing that if the elements are arranged in the order of their atomic weights in a series of lines written from left to right in the usual way, and if the table is then read downwards in parallel columns, we find that the elements of any column resemble one another. In other words, it amounts to this, that the really essential and fundamental fact of an element is its atomic weight: all its other properties, down to the nature of its compounds and their colour and solubility, could be inferred, if we knew enough, from this one given fact, the atomic weight of the element. Mendeleef, as we have seen, has already proved that a great many facts can be thus inferred.

Its Most Abstract Statement. We may then assert that the properties of an element are a function of its atomic weight. This is not all, however. It is not merely that the elements may be arranged in a single series in the order of their atomic weights, and that they then display a simple sequence in their properties. On the contrary, there is a recurrence, or a zig-zag, if one reads the list of the elements in such a fashion; and this recurrence or periodicity is displayed when we arrange the elements in columns, as has been already shown. Hence we must say more than that the properties of an element are a function of its atomic weight, and must insert another very important word, thus: *the properties of an element are a periodic function of its atomic weight.*

As the weights of the atoms of the elements rise, there is a periodic recurrence of their properties. It scarcely matters what property is taken, we find that it alternately increases and decreases as we pass from one end of the list to the other. Again, it is found that the elements of the tops of the curves—if this periodicity has been diagrammatically expressed by a sinuous curve—resemble one another, those half way down the hills resemble one another, and so forth. So recently as 1904 the veteran chemist of St. Petersburg—retaining, like most men whose lives are devoted to science, his intellectual vigour at an age when the average man is in his dotage—discussed at length the evidence for the law which he had discovered in

his youth, in the light of the recent facts which have been accumulated by chemistry; and he was able abundantly to demonstrate that the law does indeed correspond to the truth. It is as entirely compatible with the thousands of facts which have been discovered by chemists since 1871 as with the few facts which Mendeleef had predicted.

Meaning of the Law. Granting, then, that the law is true, and that it is a means of discovery and of suggesting the directions in which observation has erred or in which it should be extended, we must go much further and enquire as to the meaning or significance of the law.

If we return to the more or less suitable analogy furnished by the law of gravitation, we shall be able to understand what is meant by our search for the real significance of the Periodic Law. The fact of universal gravitation does far more for us than merely enable us to discover new planets or correct our ideas as to the movements of old ones; it teaches us that the whole universe, as we know it, is really one, and it leads us to the irresistible conclusion that the apparently complete separation between the various heavenly bodies can be only apparent, that they must all be joined together by means of a subtle medium none the less real because it happens to be invisible.

Similarly the Periodic Law of Mendeleef does far more for us than enable us to discover new elements or correct our notions as to the properties of the elements already known; it teaches us that all the elements are really forms of one element, and it leads us to the irresistible conclusion that the apparently complete distinction between them is bridged by a real medium of continuity. The analogy, perhaps, is not a bad one, for the ether which is regarded as the medium of communication between all the heavenly bodies is now also being regarded as the *Mother of matter*—the common source of all the different elements.

This, then, is the real interest of the Periodic Law, that it urgently suggests so definite a relationship between the atoms that we are compelled to regard the elements as not elementary, but as expressions of one element.

The Atom not really an Atom. More strictly the law suggests, indeed it proves, that the atoms are not atomic or "uncuttable," but that they must be made up of parts which in the successive atoms of any group of elements must be multiplied or jointed with one another in a regular and definite fashion. In fact we find an extraordinary parallelism between the atomic weight and the molecular weight. When we turn to the chemistry of the carbon compounds we shall see that there are any number of series of compounds which form definite groups, having a regular difference beween the molecular weight of each two compounds in the series, and having this regularity explained by the fact that each compound contains, for instance, one atom of carbon and two of hydrogen more than its predecessor. The relationship between the members of such a group is explicable upon the assumption that the members are compounds made up of parts which we call atoms.

If we turn, then, from such a series to a series of "elements"—so-called—that form a group under the Periodic Law, we find an almost exact parallelism. There is the same increase in atomic weight and the same regular change in visible properties as are illustrated in many instances from the chemistry of the carbon compounds. Are we not, then, forced to the same explanation: that just as the molecules of these compounds had their relationship explained by the assumption that they consisted of similar parts—the atoms—so the relations between a series of atoms may be explained if we again assume that these also consist of a series of like parts, which are the atoms of the atoms. This is the unavoidable conclusion to which the Periodic Law points us, and this it is that gives it its deep significance. But at this point the law leaves us without further guidance and with no prospect of it. Most positively the law tells us that the atoms of the elements are made up of regularly varying combinations of a unit more atomic and more elementary than any known atom or element, but when we enquire what is this unit, the law can give us absolutely no answer. No further amount of study of the law can do anything more than tell us that such a unit must certainly exist, and for a knowledge of the nature of this unit, to which the law has directed us, we must adopt a wholly new set of experiments, methods and observations.

Chemistry and Physics. This, indeed, is one of the many places where chemistry and physics must have recourse to each other. So far as the resources of chemistry are concerned we have reached a deadlock However long we continue to weigh, analyse, measure, and compare the various kinds of matter, there is no hope of discovering the common unit, the *true* atom, of which they are all composed. Chemistry, in virtue of the Periodic Law, merely asserts that there *must be* such a unit. On the other hand, physics could never have reached such a conclusion by itself. Physics, in studying matter under certain peculiar conditions—as, for instance, the behaviour of matter inside one of Sir William Crookes's vacuum tubes—can assert that there must be a "fourth state of matter," in which it is neither solid, nor liquid, nor gaseous. Physics can even go so far as to assert that matter in this fourth state must consist of minute particles of uniform size, which are distinguished by carrying each a tiny charge of negative electricity. But physics alone could never declare that *all matter* is so constituted. In order to reach this conclusion, by far the greatest achievement of science during the last decade, it was necessary for physics and chemistry to co-operate, and that is what they have successfully done.

CLERKSHIP

3

Continued from page 195

KEEPING THE BOOKS OF A SMALL FIRM

The Work of the Junior Clerk. Commercial Terms and Abbreviations. Weights, Measures, and Coinage Systems of the World

By A. J. WINDUS

Books of the Junior Clerk. As for what is termed single-entry bookkeeping, it is really almost beneath our notice. Were it not for the fact that, as we shall see, there is very little genuine single-entry bookkeeping, and that much of what passes for such is a mixture of single and double entry, we should scarcely need to waste further time on it. Examiners in bookkeeping are, however, very fond of setting, under various guises, the question, "What constitute the chief points of difference between single-entry and double-entry ?"

This will necessitate our devoting a future paragraph to the matter, but in the meantime let us suppose that we are dealing with the books of a small firm of merchants trading in the City of London, and that these books are kept by double entry. The business as yet does not need a large staff, and so the office-boy, while still retaining the Postage Book, has been entrusted also with the care and expenditure of the Petty Cash, has had his salary improved, and is now known as the junior clerk. Most of the duties of his former post have fallen to the lot of the boy in the showroom, who, if he is a capable youth, will some day become a salesman. The junior clerk has other tasks to take the place of those he has given up ; but let us first of all examine the book in which he records his petty cash transactions. Here is a specimen opening or folio ; it is called a *folio* because the number (58) appears on both sides of the opening. Had the right-hand number been 59 we should have spoken of the right-hand side as *page* 59, and of the left-hand side as page 58. The table represents Messrs. Bevan & Kirk's Petty Cash Book, with the entries therein from September 20th to September 30th, 1905. Let us consider the uses of this book.

The Petty Cash Book. First, the cash in hand may be checked at any moment. For example, the junior clerk started the day on September 20th with a balance in hand of 13*s*. 1*d*. How do we know this ? By merely subtracting from the total amount received up to that date the total amount paid away (£60 10*s*. 0*d*. – £59 16*s*. 11*d*. = 13*s*. 1*d*.). Of course, if there is more or less than this in the till, or in the cash-box, some mistake has been made, and it is the clerk's duty to discover it. To avoid the risk of errors and omissions remaining undiscovered, it is advisable to count the cash in hand at the beginning of each day, and to compare the result with the figures in the Petty Cash Book. Thus, the balance at the beginning of September 25th, according to the book, was: Receipts, £60 10*s*. ; *less* Payments, £71 16*s*. 2*d*. —that is, £8 13*s*. 10*d*. But when the clerk tested this with the money in the cash-box he found only £1 13*s*. 10*d*. in coin and an I O U for £7.

Received.	Date 1905.	Particulars.		
60 10	Septr. 19	Brought Forward . . .		
	20	Postages		
		Telegram Jones 7½*d*., Ink 6*d*., Carman 2*d*		
	21	Fares, West End 8*d*., Wire to Smith 1 0½		
	22	Fine on letter insufficiently stamped .

		Gratuities 6*d*., Fares 4*d*., Carr. on Samples 1		
	25	Pcls. Post, Williams Bros., Cape Town		
		Postages 5/-, Fares 6*d*., Paper fasteners 3*d*		
	26	Pcls. Post. Trading Co. of Madagascar		
	27	Advt. for Salesman 3/- Brown paper 1 9	4	9
	28	Travelling Exps. Mr Bevan's trip to M	3	8
	29	Telegrams : Jones 8½*d*., Smith 6½*d*. .	1	3
	30	Salaries and Wages	9	
		Gratuities 6*d*., Pencils 4*d*., Labels 1 - .	1	10
		G.L.2	13	11
		Balance, carried forward . . .	16	1
			10,	

The reason was that on the 23rd, when, as we see, an extra large amount of £15 was drawn in anticipation, Mr. Bevan borrowed £7 from Petty Cash as he was going to Manchester on a business trip, and gave the junior clerk an acknowledgment in this form:

I O U

£7,

WM. BEVAN

On the 28th, having returned from Manchester, he gave the clerk a note of his expenses, which amounted to £5 3*s.* 8*d.*, and paid back the unexpended balance of £1 16*s.* 4*d.*, whereupon the clerk entered the former amount as Travelling Expenses, and delivered up the I O U to Mr. Bevan to be destroyed. Thus the £7 originally borrowed has been duly accounted for.

Keeping the Balance. We have seen that the balance at the beginning of the day on September 20th was only 13*s.* 1*d.* The junior clerk wisely decided that he would require more money before the day was out, and obtained £5 to go on with. Notice in passing that the date column serves for both receipts and payments; accordingly £10 in the left-hand column is placed opposite the date September 30th, which means that it was received on that day. Observe, moreover, that when one or both of the date columns are blank the date immediately preceding governs; thus, having started our date column with September, it is understood that all the entries which follow are in September, unless otherwise stated. Again, although no date is placed opposite the last entry we know that September 30th is intended because that is the date immediately preceding.

If we inquire whence the money comes which the junior clerk receives for petty cash, we shall find that the whole of it comes from the bank, with the apparent exception of an amount of 10*s.*, which was the *balance in hand* at the end of August 31st, *brought forward*. But the exception is more apparent than real. £90 was drawn from the bank during the month of September, and the balance of 10*s.*, making the total of the Received column £90 10*s.*, was itself the unexpended portion of money drawn from the bank at an earlier date. It is, indeed, a very important point to remember that nowadays, in nearly all well-conducted business houses, the whole of the money received from customers and other outside sources is lodged in the bank daily without any deductions. Consequently, if there is no money in the till with which to meet expenses that have to be paid out of Petty Cash, the only way to get it is by drawing a cheque and cashing it at the bank. We shall see later how Messrs. Bevan & Kirk's banking account is affected by the withdrawal of £90 in the month of September, but we must now deal with the Paid column in the Petty Cash Book.

Petty Cash Payments. We observe that during the month a total amount of £89 13*s.* 11*d.* was expended, leaving a balance of 16*s.* 1*d.* to be carried into the Received column on October 2nd—October 1st falling on Sunday. For the purpose of analysing this expenditure under various heads—thereby reducing the labour of posting to the ledger—the right-hand side of the Petty Cash Book is ruled with several money columns and one folio column. Each payment, besides being entered in the Paid column, finds a place in one or other of the analysis columns, and it therefore follows that the cross-casting of the totals of these columns should equal the total amount expended: 7*s.* 2*d.* + 10*s.* 2*d.* + 3*s.* 4*d.* + £3 11*s.* 11*d.* + £2 0*s.* 0*d.* + £83 1*s.* 4*d.* = £89 13*s.* 11*d.* Having proved in this way the correctness of our analysis, the next step is to make use of the information it affords us. This we shall proceed to do in the next article.

The Clerk in Shakespeare's Days. Knowing what is to-day expected even from the office-boy in the way of accomplishments, it is amusing to learn from Shakespearean drama what the populace thought of clerical skill in the days of the Tudors. The passage is taken from the second part of "King Henry VI.," in which play the rebellion of Jack Cade occupies a leading part:

SCENE II. BLACKHEATH.

[*Enter some, bringing in the Clerk of Chatham.*]

Smith. The Clerk of Chatham: he can write and read, and cast account.
Cade. O monstrous!
Smith. We took him setting of boys copies.
Cade. Here's a villain!
Smith. 'Has a book in his pocket with red letters in 't.
Cade. Nay, then, he is a conjurer.
Dick. Nay, he can make obligations and write court-hand.
Cade. I am sorry for 't: the man is a proper man, of mine honour; unless I find him guilty, he shall not die.—Come hither, sirrah. I must examine thee: what is thy name?
Clerk. Emmanuel.
Cade. Dost thou use to write thy name? or hast thou a mark to thyself, like an honest, plain-dealing man?
Clerk. Sir, I thank God, I have been so well brought up that I can write my name.
All. He hath confessed: away with him! he's a villain, and a traitor.
Cade. Away with him, I say! Hang him with his pen and ink-horn about his neck.

[*Exeunt some with the Clerk.*]

Now that our junior clerk is fairly launched on his career, it will be well for him to pause for a time to consider the various technical terms with which he ought to be familiar. The short dictionary of these which follows deals only with the common terms in general use. It is not possible, of course, in so short a space, to include those which are peculiar to any one branch of the profession.

The List of Abbreviations, and the Table of Coinages, Weights and Measures for the chief countries of the world, will be found equally helpful.

NOTE. The figure 2*s.* 2*d.* near the bottom of the last column in the table on page 149 should be 2*s.* 6*d.*

To be continued

A SHORT DICTIONARY OF COMMERCIAL TERMS

Compiled by C. S. Kent.

Abbreviations in brackets are explained in the Dictionary of Abbreviations appended.

ABANDONMENT, Notice of—In marine insurance, a notice to underwriters, prior to making claim for total loss, that the insured property is *abandoned* to them.

Abstract—A summary or abridgment.

Accommodation bill—Bill of exchange, not founded upon a prior debt, but accepted for the *accommodation* of one or more parties to the bill.

Account [a/c]—Collection of items under one ledger heading. Also a statement showing cost of goods bought or sold, or the amount owed by one person to another.

Accountant—A person skilled in keeping accounts.

Account Current [A/C]—A statement in the form of Dr. and Cr., giving details of a series of mercantile transactions, in order of dates, between certain parties.

Account Sales [A/S]—Account showing particulars of *sales* effected and expenses incurred by an agent on behalf of his principal.

Actuary—A person specially qualified to make computations relating to life insurance and similar schemes.

Adjustment—Settlement of a claim, in particular of an insurance claim. In bookkeeping, the rectification of differences between two accounts or sets of figures which ought to agree.

Ad valorem duty—Duty levied on merchandise in proportion to its value and not according to quantity.

Advance—Money on account of payment for sales or services.

Adventure—Trading enterprise of a speculative nature.

Advice—Notification regarding mercantile transactions, especially despatch of goods.

Affidavit—Sworn written declaration.

Agenda—Memoranda of *things to be done*.

Agio—Difference in value between various kinds of money of the same country and denomination. Also difference between real and nominal value of money.

Allotment—Distribution of shares of an incorporated company.

Annuity—Fixed amount payable each year either in one sum or by instalments.

Annuity-certain—An annuity beginning immediately, payable over a definite term of years.

Annuity-contingent—An annuity payable only when prescribed conditions are fulfilled; *e.g.* a life annuity ceases with the death of the annuitant.

Annuity-deferred—A deferred annuity is one which begins after the expiration of a certain period.

Arbitration—The settling of disputes by decision of neutral persons (*arbitrators*) chosen by mutual arrangement.

Arbitration of Exchange—Comparison of direct rate of exchange for remittance between two countries with that obtained by remitting through intermediate places to see which is more advantageous. When sent through one intermediate place only it is called *simple* arbitration, when through more than one, *compound*.

Articles of Association—A deed containing the internal regulations of an incorporated company, by which the management of the business is governed.

Assets—The term given to the entire possessions of value of a person or company, whether cash, properties, or privileges.

Assignee—The person to whom an assignment is made.

Assignment—Transfer of title or interest in any property. This name is given both to the action and to the document making such transfer.

Attachment, Notice of—Instruction to third parties, called *garnishees*, that property held by them, belonging to a person on whom some claim is made, must not be disposed of pending settlement of claim.

Attorney—One empowered by means of a document (called the *power of attorney*) to act and sign on behalf of another.

Audit—Examination by qualified persons, called *auditors*, of books and accounts to prevent or discover fraud on the part of the person keeping them.

Average [Av.]—A term in marine insurance for dividing the loss to insurers on any damage or extraordinary expenditure in respect of ships and goods. When incurred for the common safety or benefit it is termed *general average*, otherwise it is *particular average*.

Average Stater—Person employed by the insured to prepare statements of marine insurance claims, which sometimes are very intricate.

Award—The recorded decision in an arbitration.

BACKWARDATION—Stock Exchange charge for postponing the settlement of a "bear" account.

Balance of Trade—Difference between total value of a country's imports and exports in a year.

Balance-sheet—Abstract shewing liabilities and assets of an undertaking.

Bank—An establishment where money is received for custody or deposit, and repaid on demand or according to arrangement, or remitted according to instructions.

Bank Bill—Promissory note or bill of exchange issued or accepted by a bank.

Bank Charter—Charter of incorporation of the Bank of England. First issued in 1694, but renewed in modified forms at various intervals. Confers privileges on the Bank of England which are not enjoyed by other banks.

Bank Notes—Promissory notes on bank of issue, promising to pay their face value to bearer on demand.

Bank Post Bill [B.P.B.]—Bank of England bills of Exchange for postal payments payable to order at 7 or 60 days' sight.

Bank Rate—Percentage charged by Bank of England for discounting bills of exchange.

Bank Returns—Weekly statements shewing financial positions of national banks. Issued for information of public.

Bankrupt—When a person is insolvent, *i.e.* unable to pay his debts in full and is compelled to place his affairs in the hands of his creditors, upon application by himself or his creditors he will be adjudged a bankrupt by the court.

Barratry—Fraud or criminal conduct of master or mariners of a vessel whereby either the owners or insurers of ship or cargo are exposed to loss.

Barter—Exchange of goods for goods without the aid of money.

Bear—Speculator who sells for future delivery stocks or shares he does not at present possess, hoping to buy them in meantime at a lower rate.

Bill Book [B.B.]—Book in which a record of Bills Payable and Receivable is kept.

Bill of Entry—Statement to Customs officials in prescribed form giving particulars of goods imported or shipped.

Bill of Exchange [B/E]—Order signed by one person (the *drawer*) for payment to be made by another (the *drawee*) to the drawer, or anyone appointed by him.

Bill of Lading [B/L]—Document acknowledging receipt of goods on board ship for carriage on agreed conditions.

Bill Payable [B/P]—Bill of Exchange or Promissory Note, amount of which is payable by giver at a future date named therein.

Bill Receivable [B/R]—Bill of Exchange or Promissory Note, value of which is receivable by holder at a future date, named therein.

Bill of Sale [B/S]—A Contract making absolute or conditional transfer of title to goods as security for debt.

Bill of Sight—Provisional form of Customs declaration by importer given when he is ignorant of exact nature or quantity of goods to be landed. He is thus enabled to subsequently make a correct Bill of Entry.

Boarding Stations—Places appointed where ships *bring to* so that Customs' officers may board them for examination.

Bond—A document by which a person agrees to pay a certain sum at a stated time, or under certain circumstances.

Bonded Warehouse—Secure place sanctioned by Board of Customs for deposit of dutiable goods, without payment of duty until they are *cleared*, *i.e.* removed. Goods thus stored are called *Bonded Goods*.

Bonus—An extra dividend given to shareholders in a public company, when especially good profits are made. Also term given to a periodical addition made to policies of Life Insurance out of Company's profits.

Book Debts—Amount due to a trader from his debtors as shown by his books. Generally divided into three classes—"good," "doubtful," "bad."

Bottomry Bond—The mortgage of a ship by captain or owners to obtain money needed for special purposes, such as effecting repairs.

Bought and Sold Notes—Contracts which brokers and others send to each other on conclusion of the arrangements for sales or purchases. Also known as "Contract Notes."

Bourse—Continental Stock Exchanges or Money Markets.

Brokerage—Remuneration to brokers for their services.

Brokers—Middlemen between buyers and sellers of commodities. There are various classes, the following being examples:

- Bill Brokers—persons who deal in Bills of Exchange.
- Insurance Brokers—persons who effect insurance, acting for insurers and insured.
- Ship Brokers—persons who procure cargoes for ships.
- Stock Brokers—persons who buy and sell Stock Exchange securities for the public.

Bucket Shop—Office of outside stockbroker or one who does not belong to a recognised Stock Exchange. They are often fraudulent concerns.

Bull—Speculator who buys stocks or shares, hoping to sell in the meanwhile at a high rate before time of settlement arrives.

Bullion—Gold and silver not coined into money, but in bars and other forms. Sometimes the term is used to include gold and silver in coined state.

CALL—A demand for money in payment of instalment due on shares in public companies.

Cancel—To write across a Bill, Bond, etc., the word *cancelled*, thus making it of no effect.

Capital—The amount invested in a business or public company.

Cargo—Merchandise carried on board ship.

Cash—The term given generally to coin or banknotes; sometimes includes drafts, bonds, and other readily negotiable instruments.

Cash Account—An account in which only entries relating to cash transactions are made.

Chamber of Commerce—A local association of men interested in commerce; formed for the regulation and protection of trade interests.

Charter—A crown grant which confers privileges on recipients upon the fulfilment of certain specified conditions.

Charter Party [C/P]—An agreement whereby a ship or part thereof is hired for a certain time, voyage, or number of voyages.

Cheque—A written order to a banker to pay the person named therein, or one duly authorised to represent him, a stated sum. If crossed & Co. or payment can only be obtained through another bank.

Circular Note [C N]—Letter of credit issued on foreign firms by bankers to travellers, so that the latter do not have to carry inconveniently large sums of money.

Circulating Medium—The authorised or recognised means of making payments.

Clearing—This term is used in different branches of trade to denote different actions. For instance, to Clear a Vessel is to furnish particulars of a ship and its cargo at the Custom House when it is about to leave port. Clearing in Banking is a plan adopted by Bankers for exchanging cheques and bills daily instead of presenting each one separately at the Bank or business house upon which they are drawn. Railway Clearing is carried on by the association regulated by Act of Parliament, by which English and Scotch Railway Companies are apportioned out the amounts due to them in consideration of traffic which passes over the lines of more than one company.

Collateral Security—An indirect or secondary security generally for the fulfilment of a contract or for money lent.

Commission—An allowance according to value made to agents for transacting business for others.

Company—Association of persons for developing or carrying on any business or businesses.

Composition—Part payment by a bankrupt or insolvent in settlement of debts owing by him.

Compound Interest—Interest paid not only on money lent, but also on the interest which accrues thereon from time to time, and which is added to the original amount, instead of being paid to the lender when due.

Concession—A grant of privileges by a Government to persons carrying out undertakings which will be beneficial to the interests of the country.

Consignment—Goods sent to a person (called the Consignee) by another (called the Consignor) for sale or for delivery according to given directions.

Consul—An officer appointed by the Government of a state to protect its commercial interests in a foreign country.

Contango—The additional rate of interest charged for carrying over a "bull" transaction till the next settlement day.

Contingencies—Liabilities which may probably arise, but which cannot be provided for with exactitude.

Continuation—Carrying over transactions from one settling day to another.

Contraband—Goods imported or exported contrary to the law of the country.

Contract—A binding agreement.

Coupon—A note or warrant for interest or dividend attached to transferable bonds for the purpose of being detached and presented for payment when such interest or dividend falls due.

Credit [Cr.]—Term used when goods are supplied with the understanding that payment shall be made at a future date. The person who thus sells his goods is called the Creditor and the buyer the Debtor.

Currency—The lawful coinage or means of making payment in a country.

Customs Duties—Taxes levied upon the importation or exportation of commodities; generally imposed as a means of revenue to a country.

DAYS OF GRACE—The number of days which expire after the day stated on a bill of exchange as that on which payment is due before such payment can be legally demanded. The number varies in different parts of the world, but in the United Kingdom and the United States three days are allowed on all bills of exchange except on those payable on demand or at sight.

Debenture—Deeds given by public companies as mortgages on their property for money borrowed. Should the lender not be repaid at the specified time, or in the event of default, he has a right to foreclose, *i.e.* to seize the property on which the mortgage is raised.

Debit—To make an entry on the Dr. side of an account.

Del Credere—An engagement entered into by an agent, for which he receives an extra commission, by which he guarantees that all goods which he may sell for his principal shall be paid for. This extra commission is called a Del Credere Commission.

Demurrage—A charge per day made by the owner of a vessel as compensation for its detention beyond a specified time.

Dependencies—The term given to assets which may probably accrue, but whose amount one cannot determine correctly in advance.

Deposit—The name given to a sum of money when placed with bankers at an agreed rate of interest for a stipulated time, though sometimes placed for an unlimited time. Also the part payment of goods at time of ordering and before delivery as evidence of *bona-fides*.

Depositor—One who makes a deposit.

Derelict—Vessel found at sea without anyone in charge.

Deviation—Marine insurance term for departure from terms of policy. If such departure is avoidable, it releases the underwriters from risk.

Directors—Persons who carry on the management of a business for its proprietors.

Discount—Allowance for payment when made before due.

Dishonour a Bill, To—When the drawee refuses to accept a Bill, or an acceptor fails to pay it when due, the Bill is said to be dishonoured.

Dividend—(*a*) Payment of share of profits due on money invested; also interest on National Debt. (*b*) Money paid by bankrupts to creditors reckoned at so much "in the £." That is to say, for each 20*s*. of debt he pays a sum in the proportion of his assets to his debts.

Dock—An artificial basin in which ships are received for loading and unloading cargo, or for the purpose of being repaired. The tolls charged for use of docks are called Dock Dues.

Dock Warrant—Warrant for goods in charge of dock companies giving full particulars of such goods.

Dock Weight Notes—Documents issued by dock companies giving specifications similar to dock warrants of imported goods, but given upon payment of deposit, whereas warrants are only issued after full payment.

Draft—A term used in several ways. Usually denotes a cheque or bill of exchange.

Drawback—Duty paid on imported goods, but repaid owing to re-exportation. When goods upon which excise has been paid are exported, the amount thus paid is returned and is also called drawback.

Drawer—For this term, and for Drawee, see *Bill of Exchange*.

Dunnage—Anything used to protect ship's cargo from damage during voyage.

Duties—Tax, toll, or impost upon merchandise.

EMBARGO—Order which prevents a ship's sailing or removal of goods.

Endorse—When a person (called the endorser) signs his name on the back of a draft, etc., he endorses it.

Entrepôt—Intermediate port or warehouse for the temporary reception of merchandise in course of transit.

Exchange—To give or take one thing for another.

Exchequer Bills—Promissory notes issued by Parliamentary authority.

Excise—Also called Inland Revenue. A tax or duty upon certain articles of home production and consumption.

Executor—Person appointed by a testator to see that the instructions in his (the testator's) will are duly carried out. A woman is an Executrix.

Ex-Dividend [x d]—Without the accrued or accruing dividend.

Ex-Interest [x in]—Without the accrued or accruing interest.

Exportation—Sending goods out of the country.

FAILURE—Suspension of payment by a debtor when he cannot meet demands.

Fathom—Six feet. Commonly used by sailors.

Fiduciary Loan—Loan granted to a person without security by a lender who trusts to the borrower's honour.

Firm—Business carried on by more than one person, or in the name of more than one person.

Flotsam—Goods found floating after shipwreck.

Force Majeure—Circumstances over which human beings have no control.

Foreclose, to—See *Debentures*.

Free Port—Port where no import or export duties are levied.

Freight—Charge made for carriage of goods by water. Also a ship's cargo.

Funds—Stock; capital; interest—carrying Government debts and Government stock.

GARBLE—Dross or refuse picked from spices, tobacco, etc., in sorting.

Garnishee—See *Attachment, Notice of*, for this term, and also for *Garnishment*.

Gazette, the London—The official publication of the Government.

Goodwill—The value of an established business connection.

Gross—Weight or amount without deduction whatsoever. A gross of articles means 144 articles.

Guarantee — Undertaking to fulfil another person's engagements should he be unable to do so.

HONOUR, To—To meet a claim or obligation at the proper time.

Hypothecation—The giving of a lien upon property or the pledging of documents conveying right thereto whilst retaining possession of property.

IMPORTATION — Bringing of goods into a country.

Impost—Tax or duty, generally on imports.

Indenture—Written agreement with special provisions.

Insolvent—Person whose assets are less than his liabilities.

Insurance—Contract between two parties, whereby one (the insurer) agrees to indemnify the other (the insured) against loss in the event of certain specified occurrences, in consideration of the payment of an agreed sum.

Interest—Profit derived from the employment of capital, either invested or on loan.

Interim Dividend—Provisional distribution of profits either before proper dividend or before net profits are known.

In transitu—In course of transit.

Invest—To lay out money with the idea of making profit.

Invoice—Account sent by a seller of goods to the buyer giving particulars of quantity and price.

JERQUER—A Customs official, who examines ship's cargo to prevent goods being imported without paying duty.

Jetsam—Term used in marine insurance when a ship's cargo or part thereof is cast into the sea and sinks.

Jettison—The sacrificing of a part of a ship's cargo or rigging to preserve the remainder.

LANDING ACCOUNTS—Dock companies' accounts of all goods landed, with full particulars as to weight, condition, etc.

Landing Waiter—Customs official who examines goods liable to duty after landing.

Lay Days—Days allowed for loading or unloading ships as agreed upon between owners and charterers.

Lazaretto—Building or ship in a seaport where goods from ships in quarantine are fumigated.

Lease—Conveyance letting premises or land for a certain number of years. The person who grants this is the Lessor; the person to whom it is granted is called the Lessee or Leaseholder.

Letter of Credit—Letter given by bankers or merchants authorising their agents to pay money to the bearer.

Letter of Licence—Document signed by creditors of person insolvent or in difficulties, allowing his business to be carried on for a specified time without payment of their claims.

Letter of Marque—Government licence issued in time of war authorising merchants to fit out privateers to prey upon the enemy.

Lien—Right of claim upon goods, etc., generally granted as security for debt.

Lighterage—Charge for carriage of goods by water in barges or lighters.

Limitation — Statutory period after which debts cannot be recovered, usually six years, but sometimes twenty.

Limited Liability Company—Public company in which shareholders cannot be called upon to pay more than the nominal value of the shares held.

Liquidation—The winding up of a business.

Lloyd's—The rooms at the Royal Exchange where underwriters attend to transact business. Formerly they met at Lloyd's Coffee House, whence the name.

Lloyd's Bonds—When a company has issued the full legal amount of debentures and wishes to incur liability, promissory notes are given as security, and these are called Lloyd's Bonds after the name of their originator.

Locum Tenens — Temporary substitute.

Log Book—Book kept by captain of a ship for recording particulars of voyages.

MANIFEST—Statement from owners of ship giving full details of cargo and voyage sent to their agents. It is made out previous to the ship's sailing, and a copy given to Customs authorities.

Master—Navigator of a merchant ship.

Maturity—Date when drafts, etc., become due.

Measurement Goods—Name given to goods which take up more than the average room in proportion to their weight, because freight is therefore charged upon the space. Forty cubic feet are reckoned as a ton.

Memorandum of Association — Stamped document setting forth the objects, capital, etc., of a limited liability company.

Merchandise—Goods generally.

Merchant—A trader, especially one importing or exporting.

Metric System—System of weights and measures founded on Decimals. See *Mathematics*, for full exposition.

Middleman—An intermediary, such as an agent, broker, etc.

Minute-book—Book in which are entered the records or *minutes* of the meetings of a public company or society.

Monopoly—Exclusive right to carry on a certain business in a country. Government trading monopolies have long been illegal in Great Britain.

Mortgage—Pledging of property as security for debt. Should the interest not be paid, the lender may seize the property.

Muster—A sample.

NEGOTIABLE DOCUMENT—One which, when transferred, carries with it the legal right to the property specified therein.

Nett, or Net—What remains after the total deductions, if any, have been made.

Notary Public [N.P.]—Official authorised to attest or copy written documents. He also presents for the second time dishonoured or non-accepted bills, protesting against and noting the dishonouring.

OPEN POLICY—When the value of a cargo cannot be exactly fixed, insurance is effected for an estimated sum and adjusted afterwards.

PAR—The original amount paid for a share.

Pass Book—Book given by a banker to customer and showing receipts and payments on the latter's account.

Patent—Privilege granted to an inventor, giving sole right to manufacture his invention for a term of years. Its holder is called the Patentee.

Per cent. [p.c. or %]—Proportion per hundred.

Permit—Revenue officer's permission to remove articles on which duty has been paid.

Pilot—Qualified person authorised to navigate ships in dangerous places.

Plant—Machinery, tools, etc., used to carry on a business.

Policy—Document setting forth insurance contract terms.

Post-date, To—To date a document forward.

Précis—An abridgment setting forth the most important contents of a document or documents in the form of a narrative.

Premium—(*a*) Periodical payment for insurance. (*b*) When stock is quoted above par the excess is premium.

Present a Bill, To—A bill is presented for acceptance or payment.

Price Current [P.C.]—List issued by a merchant or manufacturer to customers showing current market prices of goods.

Prime Cost—Original cost of an article before any charge is added.

Procuration — Authority to act for another.

Produce—Native productions.

Pro Formâ—Before engaging in an adventure a merchant usually has what is called a "pro formâ" account sales drawn up from past similar transactions to find out probable result of the deal. Pro formâ invoice is one sent for payment before dispatch of the goods, or in order that a prospective buyer may find out the cost of certain goods.

Promissory Note—Written promise to pay a sum at a specified time.

Prompt—The date on which payment should be made for goods sold on credit as agreed.

Proof in Bankruptcy—Creditor's affidavit that his claim on a bankrupt's estate is correct.

Pro rata—In proportion.

Proxy—The name given to a person who acts for another, and also to the document which authorises him to act.

QUARANTINE—Prohibition of communication between the shore and ships from which there is fear of infection from contagious disease.

Quotation—Prices at which a merchant offers goods.

RAILWAY CLEARING HOUSE — See *Clearing*.

Rate of Exchange—The amount given in one country's currency for a sum in another currency. Rates of exchange fluctuate under various influences.

Real Estate—Immovable property.

Rebate—Allowance given by bankers in consideration for taking up a bill of exchange before it has matured.

Receipt—Written acknowledgment that something has been received.

Reference—Declaration as to a person's commercial integrity.

Remittance—Sum of money sent.

Reserve—Funds kept apart to meet special contingency.

Revenue—Income, usually of a country.

Reversion—The right to property on the occurrence of a certain event, such as, *e.g.* the death of a person.

SALVAGE — Goods rescued, or the money paid for their rescue from damage or loss at sea, or fire on land.

Sample—Small quantity of goods given as a specimen.

Scrip—Receipt for money paid as instalments for shares in public companies.

Securities—Documents giving to the holder the right to possess certain property.

Set-off—When one person makes a claim on another and the latter makes a counter-claim on the same matter the latter claim is a set-off.

Settlement—Payment of an account.

Shares—The units of ownership in a public company, generally £1, £10, or £100.

Simple Interest—Interest on money, paid when due to the lender.
Sinking Fund—A fund built up for a special purpose, usually the redemption of capital.
Sleeping Partners — Business associates who take no active management.
Solvent—Able to pay liabilities in full.
Specie—Coined money.
Staple—The main production of a country or a town.
Sterling—The name by which English money is distinguished.
Stevedore—Expert employed to superintend the stowing away of a cargo, to prevent damage.
Stock—(*a*) Accumulation of goods or money. (*b*) The share capital of a public company.
Stock Exchange—The building in which stockbrokers carry on business.
Stop a Cheque, To—To give instructions to one's bankers not to pay a certain cheque.
Supercargo—A person on board ship in charge of cargo.
Suspension of Payment — Discontinuance of paying debts upon discovery of insolvency.

TARE—Allowance made for the weight of the package containing goods.
Tariff—Table of charges.
Tender—Offer for the supply of goods upon stipulated conditions.
Tret—An allowance of 4 in every 104 on certain goods for waste, etc.
Trinity House — The establishment which superintends British shipping interests by erecting and controlling lighthouses, etc.
Truck System—Part or total payment of workmen in goods instead of money.
Trustee—Person authorised to manage the property of another.

ULLAGE—Quantity wanting to fill a cask. Sometimes applied to the quantity of liquor in a cask.
Underwriter (U/w) — A marine insurer; so called from his signature under each policy.
Usance—Period allowed between two places for the currency of foreign bills of exchange.

VENDOR—A seller.
Voucher — Written document giving proof of money transaction.

WHARFAGE—Charge made for the receipt and removal of cargo either in loading or unloading.
Winding-up—Settling affairs preparatory to the termination of a business.

A SHORT DICTIONARY OF COMMERCIAL ABBREVIATIONS

@—To, at, or from
A/C—Account Current.
A/c—Account.

Stg.—Sterling.
Stk.—Stock.

T.—Tons.
T.O.—Turn over.
T.T.'s—Telegraphic Transfers.

U.K.—United Kingdom.
Ult.—Of last month.
U.S.—United States.
U.S.A.—United States of America.
U/w—Underwriter.

V.—Against.
Via—By way of.
Vide—See.
Viz.—Namely
Vol.—Volume.

Wk.—Week.
Wks.—Weeks.
Wt.—Weight.
W/W—Warehouse Warrant.

x c—Ex coupon.
x d—Ex dividend.
x in—Ex interest.

Yday.—Yesterday.
Yr.—Your.
Yrs.—Yours.

&—And.
&c.—And so on.
#—Numbered (as #1/20).
'—Foot.
"—Inches.
×—By (as 5 × 2, five by two) sign of multiplication.
°—Degree (as 30°, thirty degrees).
%—Per cent. (per hundred).
‰—Per mille (per thousand).
+—Plus; sign of addition.
−—Minus; sign of subtraction.
÷—Sign of division.

COINAGES, WEIGHTS AND MEASURES OF THE WORLD

M after the name of a country denotes that the Metric System is in use. For an explanation of the Metric System—which is likely to be adopted in our own country during the next few years—see MATHEMATICS, page 337. The rates of exchange are, of course, subject to fluctuation, and no fixed relation of coinages can therefore be given.

FORCES IN MECHANICAL CONSTRUCTION

Including a Study of the Composition and Resolution of Forces, with their practical application to Crane, Girder and Roof Work

By JOSEPH G. HORNER

Force. Force is that which tends to produce a change in the rate of progress of a moving body, or to bring a body from a state of rest to a state of motion. The actions of pushing, pulling, and lifting are everyday examples of force; so, too, are gravity, friction, the attraction of a magnet, the elasticity of springs, and the expansion of gases, for all these phenomena are able to cause a stationary body to move, or to affect the rate of progress of a body already in motion. The discussion of forces from the point of view of the momentum they produce belongs to dynamics; that branch of mechanics dealing with forces which so act on a body as to compel it to remain at rest is called statics, and it is with these, which balance one another and are in equilibrium, that we are now concerned.

Representation of Forces. To have a complete idea of any force it is necessary to know (*a*) the magnitude of the force; (*b*) its direction; (*c*) its point of application—that is, the point of a body at which the force acts. If we know these three essentials, the abstract idea of such a force may be set down graphically on paper. A dot may stand for the point of application; the line drawn from this dot in any given direction will represent the direction of the force; and as regards the representation of the magnitude of a force, the line will contain as many units of length as there are units of force. Thus, a force of eight pounds might conveniently be represented by a line eight inches in length, or if it were required to show a number of forces in a small diagram, the scale might be a quarter of an inch or half an inch to one pound, or hundredweight, or ton, or whatever unit of force were chosen.

Forces in Equilibrium. If one force only acts on a body, the latter will be set in motion. The least number of forces necessary to preserve a body in equilibrium is evidently two, and the body will remain at rest until one of these is removed or a new one applied. If two or more forces be applied to a body, each of them will evidently tend to move it in a certain direction, but as it is obviously impossible for any substance to move in different directions simultaneously, an intermediate course will be taken. Thus, if two men walk along opposite banks of a river, each trying with equal force to pull a boat towards his bank by means of a rope, the boat will take neither direction but proceed onward in mid-stream. Similarly, a boat does not follow the direction which either oar tends to make it take, but proceeds in a direction between the two. Evidently, then, there exists a single force which would produce exactly the same effect as these two forces acting together. Thus, in **19**, if two forces, *A* and *B*, act at a point, *O*, in a body, their combined effect will be equal to a single force acting somewhere between them. This single force is called the *resultant*, while the two forces to which it is equal are called *components*. Now, if a fresh force, *C*, be applied to *O* exactly equal to this resultant in amount but opposite in direction, the three forces *ABC* will be so balanced that their effect will be neutralised and the particle *O* will remain stationary. The forces are then said to be in equilibrium. This new force, *C*, equal but opposite to the resultant, is called the *equilibrant* and sometimes the *anti-resultant*. The process of finding the resultant of two forces is called the *composition of forces*; but if it be required to replace a single force by two or more forces equivalent in effect, the process is called the *resolution of forces*. Hence two or more forces may be "compounded" into one resultant, or one force may be "resolved" into components.

Parallelogram of Forces. The resultant of two forces acting at a point is found by the application of the famous proposition, the *Parallelogram of Forces*. "If two forces acting on a particle be represented both in direction and in magnitude by adjacent sides of a parallelogram, the direction and magnitude of the resultant of these two forces will be represented by the diagonal of the parallelogram, drawn from the point representing the particle." This will be best understood by a concrete example [20]. Suppose that it is required to find the resultant *R* of two forces, *P* and *Q* acting simultaneously on a particle *O*, *P* being equal to a force of 14 pounds and *Q* 10 pounds, the angle between the two being 60 degrees. If we adopt a scale of a quarter of an inch to one pound, *P* will be represented by a line three and a half inches long, and *Q* by a line two and a half inches in length, and the lines will be drawn at an angle of 60 degrees. Complete the parallelogram and draw the diagonal *R*. Then the line *R* represents the resultant in magnitude and direction of the two forces *P* and *Q*. In length this diagonal would measure approximately five and a quarter inches, which, according to the scale adopted represents a force of 21 pounds. Therefore the 14 pound force *P* and the 10 pound force *Q* acting at an angle of 60 degrees on the particle *O*, would produce exactly the same effect as the single force *R* of 21 pounds. And if another force equal in magnitude but opposite in direction to *R* were applied in the direction *OA*, the forces along *P*, *Q*, and *OA* would be in equilibrium and the particle would remain at rest.

By a similar method the resultant of any number of forces acting at the same point may be graphically found [21]. Let four forces acting at the point O be represented in magnitude and direction by the lines OA, OB, OC, OD. Complete the parallelogram $OAPB$; the diagonal OP is then the resultant of the forces OA and OB. Next complete the parallelogram $OPQC$; the diagonal OQ is then the resultant of the forces OP (which equals OA and OB) and OC. Finally, draw the parallelogram $OQRD$; the diagonal OR is then the resultant of the forces OQ (which equals OA, OB, OC) and OD; OR is therefore the resultant of the four forces OA, OB, OC, OD. Their combined effect both in magnitude and direction is thus represented by the force OR.

Mathematical Solutions. By this graphical method the resultant of any number of forces may be found, and in the greater number of engineering problems this method is generally sufficient, but where mathematical exactness is required, resultants of forces may be determined by trigonometrical or algebraical formulæ. By trigonometry the resultant of two forces inclined to each other at any angle may be found from the formula: $R = \sqrt{P^2 + Q^2 + 2PQ \cos A}$, where R represents the resultant, P and Q the two forces, and A the angle at which these forces act. But where the forces act at certain angles the resultant may be calculated without the aid of trigonometry, an elementary knowledge of algebra being sufficient. These particular cases are given below.

When the angle between two given forces is:

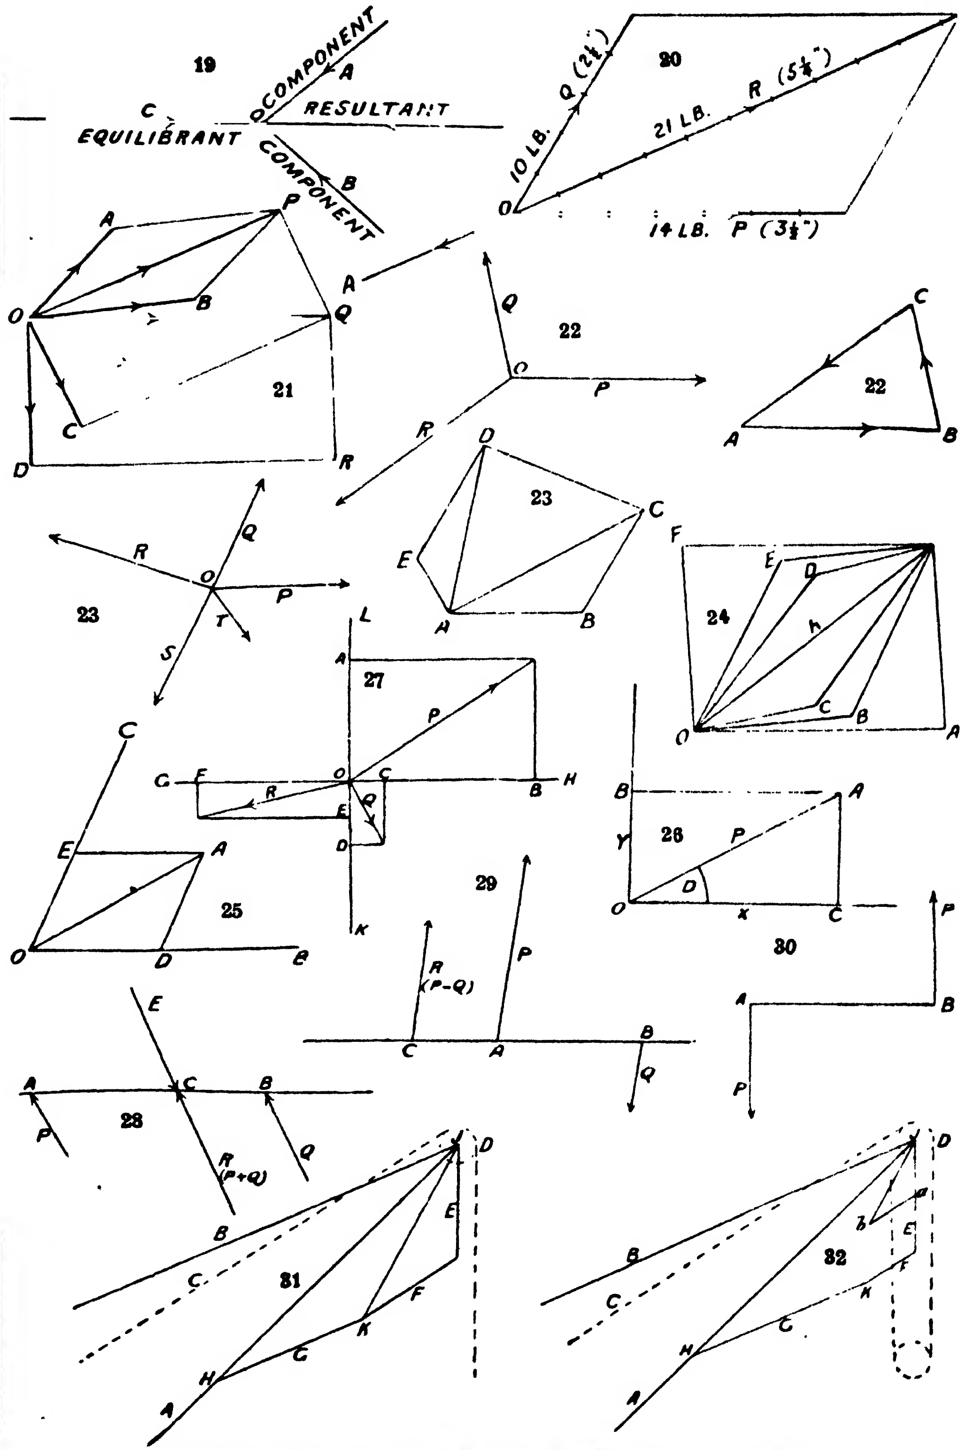
$$
\begin{array}{ll}
30^\circ, & R^2 = P^2 + Q^2 + \sqrt{3}PQ \\
45^\circ, & R^2 = P^2 + Q^2 + \sqrt{2}PQ \\
60^\circ, & R^2 = P^2 + Q^2 + PQ \\
90^\circ, & R^2 = P^2 + Q^2 \\
120^\circ, & R^2 = P^2 + Q^2 - PQ \\
135^\circ, & R^2 = P^2 + Q^2 - \sqrt{2}PQ \\
150^\circ, & R^2 = P^2 + Q^2 - \sqrt{3}PQ
\end{array}
$$

Triangle of Forces. The parallelogram of forces enables us to determine the conditions of equilibrium when *two* forces act at a point. Another highly important proposition, the *Triangle of Forces*, states the conditions under which *three* forces must act that they may balance one another or be in equilibrium. It may be stated thus: "If three forces acting at a point can be represented both in magnitude and direction by the sides of a triangle taken in order, then these three forces will be in equilibrium." Thus in the related diagrams 22, if the three forces P, Q, R, acting at O, are parallel to the sides AB, BC, CA respectively of the triangle ABC, and if also the lengths of these three sides are proportional to the magnitudes of P, Q, R, then shall the forces P, Q, R be in equilibrium. Conversely, if a body remain stationary under the action of three forces acting on a particle, then any triangle which can be drawn with its three sides parallel to the directions of the three forces will have those sides proportional in length to the magnitudes of the forces. It is obviously necessary to take the sides of the triangle "in order," that is, the arrow heads should follow one another in their triangular course as seen in the diagram. If one be reversed, then the triangle would represent two forces and their resultant.

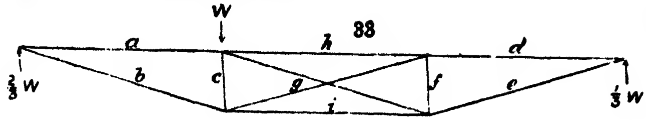
Polygon of Forces. The conditions under which a body remains at rest when a number of forces act in the same plane on one point are stated by the *Polygon of Forces*: "If a number of forces acting at one point can be represented both in magnitude and direction by the sides of a closed polygon taken in order, then these forces will be in equilibrium." In the related diagrams 23 the forces P, Q, R, S, T, acting at O, are represented in magnitude and direction by the sides AB, BC, CD, DE, and EA respectively of the polygon $ABCDE$. Now, AC is the resultant of AB, BC; similarly AD is the resultant of AC and CD; again, AE is the resultant of AD and DE. That is, the resultant of forces P, Q, R, S is represented by AE. But as the force T is represented by EA, which is equal and opposite to AE, the forces are kept in equilibrium.

Resolution of Single Forces. Just as two or more forces may be compounded into a single resultant which would have an exactly similar effect on a particle, so any single force may be resolved into two components producing an equal effect. Obviously, these two components may be in any direction whatever, as an infinite number of parallelograms may be drawn with the same line for their diagonal. For example, in 24 the force R may have for its components any of the pairs of forces represented by the lines OC, OD; OB, OE; OA, OF. It is also evident that any one pair of these forces is equal to any other pair. The greater the angle becomes between any two of the components the greater is their tendency to destroy each other's effect. It is then a simple matter to resolve a force into two components in given directions [25]. Let OA represent the force, and OB, OC the directions along which the components are to act. From the point A draw AD and AE parallel to OC and OB respectively. Then, from the parallelogram of forces it follows that the force OA is equal to, and may be replaced by, the forces OD, OE.

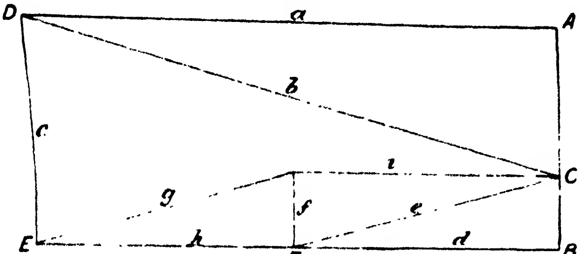
In actual practice it is most often required to resolve a force into components acting along and perpendicular to a given line—*i.e.* at right angles to each other. In 26 let OA represent the given force P. Then OC and OB will represent components acting at right angles, and if these be designated X and Y respectively, the relations between the three forces will be shown by the equation, $P^2 = X^2 + Y^2$. When the angle D is known, either X or Y can be found. The component X is obtained by multiplying P by the cosine of the angle D; Y by multiplying P by the sine of the angle D. In certain cases it is also possible to find X and Y without the aid of trigonometry. Thus, when OA is inclined to OC at an angle of 45 degrees, OCA will be a right-angled isosceles triangle, and it is clear that $OA^2 = 2\,OC^2$; that is, $OC = \frac{OA}{\sqrt{2}}$, or $X = \frac{P}{\sqrt{2}}$, and $Y = \frac{P}{\sqrt{2}}$. Similarly, it can be shown that when the angles at which the force is inclined



ILLUSTRATIONS OF THE COMPOSITION AND RESOLUTION OF FORCES



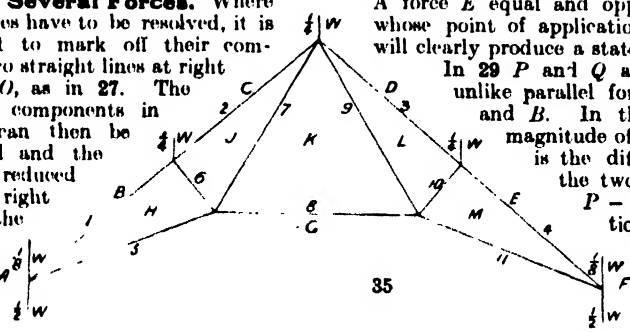
33



34

to two perpendicular lines are 30 and 60 degrees respectively, the components will be $\frac{\sqrt{3}P}{2}$ and $\frac{P}{2}$ respectively.

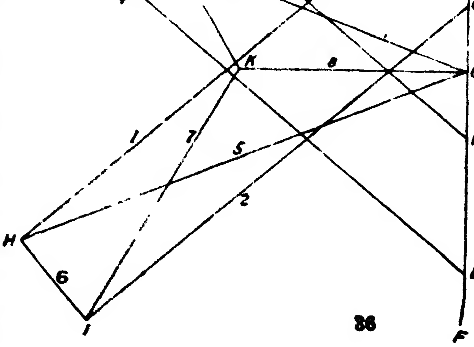
The Case of Several Forces. Where a number of forces have to be resolved, it is most convenient to mark off their components along two straight lines at right angles through O, as in **27**. The sum of all the components in each direction can then be readily obtained and the original forces reduced to two acting at right angles. Let the forces P, Q, R act at O. Through O draw lines GH, KL at right angles, and resolve each force into two components on these lines. Then $P = OA + OB$; $Q = OC + OD$; $R = OF + OE$. Now, along the line GH there are components acting in opposite directions, some to the right $(OC + OB)$, and one to the left (OF). Therefore $OC + OB - OF$ will represent the resultant of the forces acting in this straight line. Similarly, $OA - OE - OD$ gives the algebraical sum of the forces acting in the other direction. If the algebraical sums of the components along these lines be represented by X and Y, and if R denotes the resultant, then $R^2 = X^2 + Y^2$.



35

To ensure equilibrium, the sum of the components of the forces along two straight lines at right angles must be separately zero. For if the system of forces is in equilibrium the resultant, R must be zero, that is, $X^2 + Y^2 = O$. But since the squares of all numbers are positive, X and Y must be separately zero, and so $X = O$ and $Y = O$. By calculating the forces which act in two directions at right angles and substituting for X and Y in the above equations, many problems of this class may be solved.

Parallel Forces. When two or more forces act in directions parallel to one another and at different points they are parallel forces—*like*, if they all act in the same direction; *unlike*, if in opposite directions. In **28**, let P, Q be like parallel forces acting on a body at the points A, B. Then (*a*) the magnitude of the resultant equals the sum of the forces, or $R = P + Q$; (*b*) the resultant acts in the same direction—that is, R is parallel to P and Q; (*c*) the point of application of the resultant R divides the line AB into two parts inversely proportional to the forces—*i.e.* AC is proportional to Q, and BC to P, while R is proportional to AB. Hence $P \times AC = Q \times BC$. Or, $\frac{AC}{CB} = \frac{Q}{P}$. This provides a simple means of finding the position of the resultant, for it is only necessary to divide AB into two parts proportional to the numbers representing the parallel forces. If P be twice or three times Q, then CB will be twice or three times AC. The resultant will evidently always be nearer to the greater force. A force E equal and opposite to R, and whose point of application is also at C, will clearly produce a state of equilibrium. In **29** P and Q are unequal and unlike parallel forces acting at A and B. In this case (*a*) the magnitude of the resultant R is the difference between the two forces, or $R = P - Q$; (*b*) the direction of the resultant is the same as that of the greater force P; (*c*) the point of application of the resultant divides the line externally into two parts, which are inversely proportional to the forces.



36

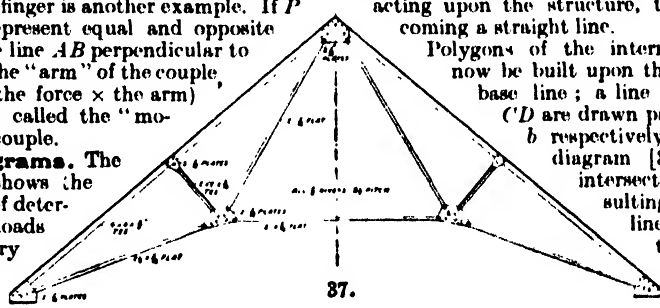
Hence $P \times CA = Q \times CB$. Or, $\frac{CA}{CB} = \frac{Q}{P}$

Referring again to **29**, it is clear that any force R can be resolved into two parallel components P, Q, if BC is to AC as P is to Q.

The resultant of any number of parallel forces in the same direction is found by obtaining the resultant of any two, then the resultant of this resultant and another force, and so on. The final resultant is parallel to the forces and is equal to their sum; but if they act in opposite directions, their resultant equals the difference between the sum of those in one direction and the sum of those acting in the opposite direction.

Couples and Moments. When two parallel forces are equal but unlike (*i.e.* opposite), there can be no resultant, no single force capable of producing the same effect. A body under two such forces cannot be in equilibrium, but will rotate. Two forces such as these form a *couple*. The swinging of the compass needle is a common example, the couple in this case consisting of two equal, parallel, but opposite forces acting north and south respectively. The spinning of a top between the thumb and forefinger is another example. If P and P [**30**] represent equal and opposite forces, then the line AB perpendicular to them is called the "arm" of the couple, and $P \times AB$ (the force $\times$ the arm) equals what is called the "moment" of the couple.

Crane Diagrams. The diagram [**31**] shows the usual method of determining the loads upon an ordinary crane jib and tie. A is the centre line of the jib, B is the centre line of the tie rod, C is the chain line, and D is the jib head pulley.



37.

Draw a line, E, plumb from the centre of the pulley, J, and measure its length by a scale of tons, say, one-eighth of an inch, or quarter of an inch per ton, the total length representing the load on the crane by the method of **20**, but substituting tons for pounds. A line, F, is now drawn to the same scale, and the same length, but parallel to the chain line C. From the point thus obtained, K, a line, G, is drawn parallel to the tie rod, B, until it intersects the jib line, A, at H; the length of the line, G, then represents the load on the tie rods, and the length of the line, H to J, represents the load on the jib. Another line may be drawn from point K to J, and such a line measures the resultant of the chain loads upon the pulley pin at J.

In **32** a similar diagram is shown to illustrate the case of a crane which lifts its load with two falls of chain and snatch block, the return chain being anchored to the jib head as usual. The same procedure is followed, but the line, F, is now only half the length, because although the full load takes effect on line E, yet only half of it is sustained by the chain C.

To obtain the load upon the pulley pin, a separate triangle may be constructed upon the plumb line E by drawing a line, ab, to represent the direction and magnitude of the load on the chain C, the distance, Ja, being, of course, the same; the line, bJ, then gives the resultant upon the pin.

Reciprocal Diagrams. It is, however, not always convenient, nor indeed practicable, to develop a polygon of forces upon the drawing of the framework itself. In such cases it is usual to construct a reciprocal diagram. Fig. **34** gives an example of one applied to the trusses of a traveller beam [**33**] above it. Assuming the load W [**33**] to be directly over one of the struts, the reactions upon the cradles, or end supports, can be determined, and figured thereon. To construct the diagram, mark off to a scale of tons a vertical line, AB [**34**], representing the load, W, acting in a downward direction, and upon the same line mark the reactions or upward forces at the cradles; thus BC represents the reaction on the right-hand cradle of [**33**] = one-third W; while CA represents that on the left-hand cradle = two-thirds W, the two together being equal and opposite to W; the line AB, BCA [**34**] is then a closed polygon of the external forces acting upon the structure, the polygon becoming a straight line.

Polygons of the internal forces may now be built upon this, using it as a base line; a line AD and a line CD are drawn parallel to a and b respectively, in the upper diagram [**33**], until they intersect at D, the resulting lengths of these lines a b represent the loads upon them. A vertical line is now drawn from D to E, representing the load on the member c, which load is W. Starting from the base line again, a line, BF, and a line, CF, are drawn from D to E, representing the load on the member c, which load is W. Starting from the base line again, a line, BF, and a line, CF, are drawn parallel to d and e respectively, until they intersect at F, the resulting lengths representing corresponding loads on those members. From F the lines f, g and h are drawn parallel with their members, and the whole polygon is completed by i.

The above examples are typical of methods adopted in actual practice. In dealing with more complicated framings, particularly those in which the directions of the forces are not very apparent, it is necessary to adopt a system of notation whereby the polygons can be regularly constructed, and the direction of the various forces clearly seen.

Roof Truss. Considering next a simple roof truss as shown in **35**, it is usual to ascertain the loads upon the various members by means of a reciprocal diagram as in the previous example, but the employment of *Bow's notation* is adopted in order to facilitate the construction.

The frame diagram [**35**] is first of all laid down to a convenient scale, and all external loads and

reactions indicated thereon by direction arrows, then the diagram is lettered from left to right with a letter in each space between any two external forces, and also in each of the internal spaces. It is sometimes convenient to figure each separate member of the framework.

The polygon of external forces and reactions is then plotted to a scale of cwts. or tons; in this example, as in the previous one [34], this polygon becomes a straight line.

AB [36] represents the force one-eighth *W* lying between *A* and *B* on the frame diagram. *BC* represents the force one-fourth *W*, which lies between *B* and *C* on the frame diagram, and so in turn are laid down the forces lying between the letters *CD*, *DE*, and *EF*; then the reactions *FG* and *GA*, each equal to one-half *W*, complete the polygon.

The internal load diagram is now drawn, commencing with member 1 lying between *B* and *H* on the frame diagram [35]. This is laid down as line *BH* exactly parallel to member 1 [35], its length being determined by its intersection with line *GH* drawn parallel to member 5; *CJ* and *HJ* may now be drawn parallel to members 2 and 6; then to complete the first half of the diagram, lines *JK* and *KG* are drawn parallel to members 7 and 8. The accuracy of the diagram is tested by its symmetrical completion, and the perfect "closing" of the last line. The nature of the loading, whether compression or tension upon any member, may be determined by the following rule.

Read off the letters on either side of the member in question on the frame diagram in the order in which they occur when turning round either joint, connected with that member in the direction of lettering.

Place an arrow on the corresponding line on the load diagram pointing from the first toward the second letter.

Transfer the arrow back to the frame diagram: if the arrow points toward the joint the member is in compression, if it points away from the joint the member is in tension.

It will be noted in the above example that the external forces are all assumed to be in a vertical plane, whereas in fact a roof has to sustain oblique forces due to wind action. With small roofs it is usual in practice to resolve these oblique forces into vertical loads, and add them to the ordinary dead vertical loads in order to simplify the diagram; when dealing with large roofs, a separate diagram is frequently set out to determine the internal loads due to wind pressure, and the results are added to the ordinary diagram for vertical loads; alternatively a combined diagram can be constructed.

In the above examples the load diagrams are used as a basis for calculating the scantlings of the structure in question. The main body of any member is subjected to either tension or compression, and the material can be proportioned accordingly, whilst the joints must be designed to sustain bending or shearing actions, according to detail of construction.

In the case of the jib and tie [31 and 32], the jib section is calculated as for a column, free at both ends; the tie rods are, of course, in tension, care being taken to see that the ends are forged to be of equal strength to the bar; the head pin may be subjected to a bending moment, or to shearing forces, only according to construction. It is not usual, except in cheap cranes, to attach the tie rods directly to the same pin that carries the head pulley.

With regard to the trussed beam [33], the same remarks apply generally to the tension and compression members; the beam itself, however, has to sustain a bending moment, being at its maximum when the load is in the centre of any bay. In proportioning the tie rods, the screwed ends must be swelled up in order that the area under the thread shall not be less than the area of the rod itself.

When considering framed structures composed of a considerable number of members it is sometimes useful to tabulate them together, with the condition of stress, and an abridged calculation of scantlings. An example of such is given below [37], applicable to a diagram like that in 35, together with a truss detail drawn from same.

TABLE OF MEMBERS AND SCANTLINGS.

Member.	Tension.	Compression.	Scantling.
BH and *EM*	..	68 cwts.	Strut 11 ft. long, 4" × 4" × ½" Tee bar. Factor of safety = 5.
CJ and *DL*	..	58 "	Same section as above for convenience.
HG and *MG*	56 cwts.	..	Area required at 5 tons per □" = ·56 □" 2¼" × $\frac{5}{16}$" flat, − ¾" rivet-hole = ·6 □".
HJ and *LM*	..	12·5 "	Strut 4ft. long, 2" × 2" × $\frac{5}{16}$" Tee bar. Factor of safety = 18.
JK and *LK*	34 "	..	Area required at 5 tons per □" = ·34 □" 2" × $\frac{5}{16}$" flat, − ¾" rivet-hole = ·43 □".
KG . . .	27 "	..	Same section as above for convenience.

It will be observed that some members have a larger factor of safety than others; this arises from manufacturing conditions. There is, for instance, a difference of loading on members *BH* and *CJ*, but it is obviously cheaper and more convenient to run a through member and so theoretically waste material in *CJ*. Again, in *HJ*, *LM*, and *KG* there is a theoretical waste, but these members, if designed with the same factor as the others, would give great trouble in manufacture and in erection, and would certainly give unsatisfactory results on account of their lightness; it is due to this fact that timber trusses are not economical of material.

THE STORY OF INDIA AND EGYPT

Hindostan. Buddha and Buddhism. Alexander's Invasion of India. Tamerlane. The Hindu State. Egypt and Its Dynasties

By JUSTIN McCARTHY

Hindostan. India, the great land which has, during most of its history, been described as Hindostan, traces its origin in ages long before ordinary records of national development. In the earliest days of which we can obtain any knowledge, it was inhabited by several aboriginal races who left philological traces and rude monuments. These races were modified by many invasions, Dravidian and others, one of which, an Aryan invasion, gave the early Hindu or Vedic system of religion. The history of India, as we now study it, was made, for the most part, by the Aryan race, a fair-skinned people who settled in many parts of the country, and possessed a certain degree of civilisation.

The crowding together of these different peoples caused much internal disturbance, and led to a vast stream of emigration which flooded other parts of Asia and streamed over into Europe. The story of this prolonged struggle has been preserved in the Vedas, the earliest of the Aryan sacred books, which books have been justly described as holding a place among the most ancient monuments of the human race. Many epic poems were created among those imaginative peoples, and some of them show remarkable affinities to the Greek Iliad, and were, like it, the gradual work of centuries. One of these epic poems, which tells of the conquest by the Aryans of a great part of Hindustan and the Island of Ceylon, may be ranked with the works of Homer and of Virgil.

Buddha. The Hindu, or Vedic, system of religion became corrupted, and it was reformed by Buddhism more than five hundred years before the Christian era. Buddhism is the religion preached by Buddha, a name which signifies the Wise. Buddha's father, the story tells, was born of a royal family, but at an early period of his life Buddha renounced his rank and wealth and went out into the desert to seek for the actual truth and to find inspiration there. After seven years of voluntary exile Buddha returned to his home and his people, and began to preach to crowds of every sort that he could gather around him. He taught what he believed to be the true doctrines, teaching only through the utterance of parables. Buddha's preaching was directed against Brahmanism by insisting on the equality of all men before the moral law, and by substituting virtues which consist in the practice of good deeds for the spurious and fantastic virtues set up by a humanly devised ritual.

The promise of salvation, of union with the divine essence, made to the Brahman alone, was superseded by the recognised capacity of all men, through their merits, to win Nirvana, or deliverance. Buddha broke up priestly heredity by calling to the priesthood the poor and the beggars who devoted themselves to a religious life. He set up for human beings six essentials of perfection to be sought for and obtained by all men: knowledge, which must apply itself to distinguishing between the true and the false; energy, which enables man to strive against man's worst foes, the pleasures of the senses; purity; patience in enduring passing or imagined troubles; charity, the great bond of society; and almsgiving, the necessary result of the doctrine of charity. Buddha announced that he had come to give wisdom to the ignorant, and declared that even the man of noblest intentions and purpose could not accomplish much towards his own salvation unless he made it part of his work to comfort the afflicted, and render help to the miserable. His doctrine he defined as a doctrine of pity. "The prosperous find it difficult, and pride themselves on their birth, but the way of salvation is open to all who annihilate their passions as an elephant overturns a hut made up of reeds."

The Moral Code of Buddha. This simple and pure moral code came as a strange novelty to those who had to endure the dominion of the Brahma system with its law makers, believed to be divinely appointed, its castes, and its eternal aristocracy, set up and maintained by the everlasting rule of the appointed law-givers. We are told that his preaching attracted such masses of converts and became so powerful that, notwithstanding all the efforts which the priestly orders could make to destroy his work, he was enabled to carry on his reforming crusade until he had attained an advanced old age without having to make any appeal to his masses of devoted followers for the use of force in order to sustain him in his mission. Indeed, he preached against the use of force for the establishment of reform, a doctrine very unlike that inculcated by most other innovators, in Asiatic or other countries.

Jainism, which came of the same school of doctrine as Buddhism, had arisen about this time, and remained an existing faith after Buddhism had been banished from India.

Alexander's Invasion of India. A memorable event in the history of India was the invasion of Alexander the Great. Up to the opening of that invasion India had been known to the European world only by name, as a vague sort of region beyond European ken, peopled by races of different colours. Alexander had made many expeditions into Asia already, had conquered many native princes, had traversed Palestine, had helped to free Egypt of Persian domination, had been hailed by the

Egyptians as their deliverer, and had founded the city of Alexandria. Alexander fought his way through a great part of India, and established Greek colonies in many regions. He had, in fact, a gift for colonisation as well as for war, and wherever he made his way he seems to have been able to impress each invaded race with some interest in the language and literature of Greece, and some sense of the importance attaching to Greek institutions. His influence was two-fold, it will be seen, for, while he carried into India ideas brought from Europe's early civilisation, it was through him that the attention of Greece and other European countries first became drawn to the ancient civilisation of India.

Rise of the Mahrattas. The richness and the varied productiveness of the soil in many Indian countries soon became a source of attraction to merchants from all lands civilised enough to spread trade by foreign travel. The Mussulmans of Persia began to invade India, and then there were Turkish invasions and new incursions of the Mongols, one of whose race established at Delhi the dynasty of the Great Mogul which lasted until modern days. The supremacy of the Mogul Empire was overthrown by the rise of the Mahrattas. "Wild Mahratta battle" was destined long later to be a thing of meaning to men of pale face in the days when the Feringhee crossed the Black Water, and laid his hand on Hindu and Mohammedan, Mogul, and Mahratta alike. Thus it will be seen that the native race of India lost its independence at a very early period of its history, but it always retained some of its leading peculiarities in religion, in organisation, and in literature. In the sixth century A.D. Buddhism was suppressed by Brahmanism.

One of the cardinal principles of the Brahmans is that their divinity, Brahma, divided the people from the first into four distinct and separate castes—the priests, the warriors, the merchants, and the artizans. Of these, the first two were established as the ruling castes, and marriage was forbidden between them and the lowest caste. To that lowest order, also, belonged the descendants of the aboriginal population, the conquest of which had opened India to the outer world. Only those who belonged to the caste of the Brahmans, or priests, had the right to expound or even to read the sacred books, and as all the knowledge then within the reach of Indian populations was supposed to be contained in these books, the Brahmans were looked up to as the teachers of everything intellectual, as poets, as physicians, and as expounders of laws. Many struggles took place before the warrior caste could be brought to accept this ascendency and even supremacy being accorded to the priestly teachers.

Tamerlane, Emperor of India. In 1001 A.D. came the Mohammedan conquests under Mahmud of Ghazni, who invaded India through the passes of the Suliman Mountains, and the greater part of India came for a long time under Mohammedan rule. Two hundred years later India was invaded by Genghis Khan, some yet later Mongol invasions were repulsed, but in the fourteenth century Tamerlane, the famous Tartar chief, entering Delhi, declared himself Emperor of India. The history of India had already begun to blend itself with that of the whole outer world, and we shall have occasion to refer to it again and again in this narrative.*

The religious and political organisation which India accepted about nine hundred years before the Christian era is in its principle characteristic of the prevailing system to this day. That principle claims to set forth, as on the authority of revelation from the higher powers, the origin of the world and of the institutions prescribed for the Indian race. The divine authority of the ancient Vedic is still recognised, but all these are declared to be subordinate to Brahma, the absolute ruler of the heavens and the earth.

Keystone of the Hindu State. The whole system bears a certain resemblance in its principal qualities to that scheme of the world's origin and growth which is set forth in the Old Testament. It has been for the most part among the Indian races a system which has undergone no change down to the present day. *The Indian Review* a monthly magazine published in Madras, and issued for publication among English-speaking readers, has in its number for April, 1905, an interesting and instructive article, evidently written by one of the Hindu race. It tells us that "our idea of the sovereign as the parent of his people is the basis of Hindu politics." The writer says that it is "what may, in the language of modern politics, be called the keystone of the constitution of the Hindu state." Then he goes on to say that "the idea of one's own rights is foreign to the Hindu ideal in every department of life." According to this doctrine there is no "self" for the soul or the body of the sovereign or the individual, and the sovereign can seek no salvation for himself individually, but can only obtain it by the faithful discharge of his duty to the highest power and to his subjects and to all around him.

This is, indeed, the central principle of all religious teaching in the modern and the European world, as well as in that of the Hindu races, and is probably not more rigidly carried out by individual beings, whether rulers or subjects, in the one instance than in the other. But it is of much interest for readers to know that the accepted religion of the Hindus takes as its central and guiding principle that doctrine which is the very essence of the Christian faith.

Hinduism and Christianity. It would be needless to say that the existence of so pure and exalted an ideal religious code did not always prevent the Hindu races and the Hindu rulers from quarrelling among themselves, and carrying on fierce wars of conquest and annexation. We have seen throughout our most

* Perhaps this may be a suitable place in which to mention the fact that throughout this History we shall make it our rule to print foreign names according to the recognised fashion of English spelling. In every country it becomes the custom to print foreign names according to the country's own fashion of spelling them, and it would lead only to useless confusion if we were to attempt a correct rendering of the genuine and native nominations given to foreign regions and foreign celebrities.

modern European history that the teachings of Christianity have not always been able to protect peaceful populations from the terrible results brought about by the reckless ambition of Christian rulers. Our object at present is to show that throughout great parts of India's vast territories there have been almost from the birth of recorded time, and still are, populations which are taught and accept the teaching of doctrines proclaiming as their essential principle the existence of a higher power regulating the destinies of humanity, and the truth that man's salvation depends on the discharge of the duties he owes to the higher power and to his fellow-beings, and not merely to his own personal protection, credit, respectability, and worldly advancement.

It is not our intention now to give a minute account of the religious creeds of India; we wish to call the reader's attention to the fact that the principal religious organisations of India have from the earliest periods of which we know anything, and down to the present, borne a greater essential resemblance and affinity to the doctrines of Christianity than to those which were taught and accepted among the Greeks and the Romans, and in later days among the followers of Mahomet. In the study of Indian history we are not helped so much by the existence of ancient monuments as we are in the history of Egypt, Greece, or Rome. There are, indeed, many ancient monuments to be found throughout India, but not many of them bear inscription, device, or symbol which could expound to the student their religious or historical significance.

Egypt. Egypt is, beyond every other country, a land of monuments. All her earlier history is to be traced out through the forms and the inscriptions of her monumental buildings. The great Pyramids themselves, those majestic relics of the far past, those monuments with which the modern tourist from all parts of Europe and the United States is now so familiar, are the tombs of some of Egypt's early kings and are inscribed with the story of their lives and their deeds. There are still to be seen here and there throughout Egypt whole cities which might be described as records of Egyptian history, erected as they were to commemorate the founding or the fall of some dynasty, the establishment or the expulsion of some new invasion. Almost every ancient building in the land is a tomb or a house of prayer, or a tomb and a house of prayer.

Nor are these relics of the historic past to be found only on the surface of the Egyptian soil. Active research throughout Egypt has for centuries past been discovering monuments and houses of prayer below the surface of the earth, and even in the most recent days the patient skill of the explorer into subterranean caverns is still finding new evidences of that worship of divinities and worship of ancestors which belonged to the very heart of the Egyptian race.

From all these memorials it is certain that at the time when the Egyptian populations first came to have any record in actual history they must have already arrived at a very advanced stage of civilisation. The building of the great Pyramids marks an era nearly 4000 years before the birth of Christianity, and the Pyramids themselves, and all the public monuments contemporaneous with them, give the clearest proof that for ages before that period Egypt had been brought to a state of highly advanced civilisation, in the artistic sense at least, entirely unlike that which could possibly have belonged to the doings of merely savage races.

Influence of a Race of Slaves. Egypt was naturally, from the peculiar fertility given to almost the whole of its length and breadth by the frequent overflowings of the sacred river the Nile, a most desired and coveted place of settlement for the inhabitants of neighbouring regions on whom the heat of the African desert burned with unmitigated fierceness. The Egyptian soil was therefore frequently invaded by neighbouring tribes, who endeavoured to settle on the land, and of whom large numbers succeeded in establishing a permanent home there. Then again the Mamelukes, who were originally a race of slaves imported by Egyptian rulers from Turkey and Circassia, became a permanent part of the population and had an important influence on Egyptian history.

The earliest Egyptian race concerning whom we can form any distinct idea appear to have been a red-skinned race, and to have belonged to the population described in Genesis as the tribe of Ham. Those people, who were called Cushites, constituted for many centuries the basis of the population along the shores of the Indian Ocean, the Persian Gulf, and the Red Sea. They divided themselves into several small states, which at last came under the domination of one ruler, and thus established the first royal Egyptian race. This royal dynasty must have been called into existence at least 5000 years before our historical era.

Religious Beliefs. The religious belief which prevailed amongst the early Egyptians was that the country had first been ruled by the gods and then by the demi-gods, who came down to earth in the form of a priestly caste, and that these had at last either voluntarily yielded, or had been compelled to yield, their ruling power and their general influence to a warrior dynasty which was better fitted than a priestly caste to work out to the happiest effect the destinies of Egypt, and to maintain her independence.

For a long time there were two distinct religions prevailing throughout Egypt—the faith professed by the priests and the faith adopted by the people. The religion adopted by the people was the ancient fetichism, and created a number of divinities, many of whom it invested with some of the attributes influencing the life of human beings. The hopes, the passions, the ambitions, all the various cravings of human nature, were represented in this strange form of theology, and it had its divinities also in the form of animal creatures, such as the bull Apis of Memphis, and even many monstrous creations made up of the head of an animal and a human body, or of the head of one animal and the body of another.

The religion of the priests was based upon the principle that there was a struggle between good and evil going on everywhere, the struggle for good represented by Osiris and the struggle for evil represented by Typhon, the god of darkness and destruction. Osiris was typified by the sun, the principle of all life, while nature was typified by Isis, and these two had a divine offspring, Horus. This was a much more exalted form of creed than that generally adopted by the Egyptian people, but as time went on it began to descend more and more into vague limitless polytheism or fetichism.

Ancient Dynasties. Before the Persian invasion Egypt had already seen, according to historic monuments, some 26 dynasties, and the Persian invasion took place some five centuries earlier than our Christian era. The world has learned the names and something of the doings of the leading sovereigns during those dynasties, for they are carved on the monuments which were erected all over the country. Little is known of the earliest among those dynasties, but with the fourth dynasty we begin to have the records of a civilisation which must have been absolutely unknown to any other part of the world at the same time.

Architecture began to flourish then in forms which Egypt has never since surpassed, in forms which few other countries from that time to this have ever excelled or equalled. Pyramids, temples, and other buildings arose and bore testimony to the marvellous architectural skill of their builders; statues were chiselled which could have held a fair rivalry with the work of Greek and Roman sculptors, and the paintings and inscriptions on the walls of Egyptian temples accomplished the work of history as well as that of art, for they not only prove the intellectual and artistic capacity of the workers, but they also tell to later times what the kings and rulers, the industry, commerce, and agriculture of the land had already accomplished and were accomplishing.

Dark Periods. There are intervals in the story of those dynasties where you find little or no trace of artistic culture or of history recorded in monumental buildings. It is evident that during those periods thus obscured there must have been great invasions, or other calamities, absorbing the whole strength and mind of the country, because after a certain lapse of time we find the historic monuments once again coming into existence and the Egyptians returning to their place in art and in civilisation. During some of these intervals of comparative darkness royalty itself seems to have been banished from the land. Under the kings of the twelfth dynasty it resumed its place, and the natural boundaries of Egypt seem to have been restored. The Egyptians must have had for their time a wonderful mastery of applied science. Under that twelfth dynasty was constructed an artificial reservoir known as Lake Moeris, which covered more than 60 square miles, the object of its creation being to regulate the overflow on the left bank of the Nile. Another sovereign undertook and accomplished the erection of the great pillared hall at Karnak, which is still regarded as one of the triumphs of Egyptian architectural art, and indeed of the world's architectural art.

Invasion of Shepherds. One of the most remarkable invasions which interrupted the succession of the regular dynasties was that which is known as the invasion of the shepherds about 2200 B.C. According to legend and such records as have been preserved, this was an irruption of a pastoral race, who, finding that the conditions of their own soil did not admit of prosperity, passed from Assyria into the valley of the Nile by the Isthmus of Suez, actually took possession of a great part of middle Egypt, and set up a realm of their own with its kings. This dynasty was established at Memphis, and built fortifications in order to prevent other hordes of immigrants from following their example and endeavouring to found realms in their turn. It is generally understood that it was one of those rulers to whom Joseph, the elder of the two sons of Jacob by Rebekah, was Minister. The Shepherd or Hyksos dynasty was ultimately expelled from Egypt, but some of the race still continued to be occupants of the Egyptian soil, and left their physical traces among the Egyptian populations.

After the expulsion of the Shepherds Egypt seems to have recovered her old art and civilisation, and again we begin to have the monumental records of passing history. One of the sovereigns of this restoration was Thothmes III., who conquered Western Asia and the Soudan, and is described in some lines carved on a monumental pillar as one "who set the frontiers of Egypt wherever he pleased." Another of these sovereigns is described by Greek historians as Memnon, the Son of the divine Aurora. The Greeks were now beginning to take a deep interest in Egyptian civilisation, and before long we shall find that some of their great historians set themselves to work to describe and explain its condition.

Inaccurate Historians. The Greek explorers were generally much inclined to explain everything they found in Egypt by some reference to the religion and the history of Greece, and were apt to invest the monuments and the other records which they found with a pervading aroma of Greek mythology. As they converted one of the Egyptian Princes into Memnon, the King of the Speaking Statue, which at the rise of every sun paid homage by salutation to Aurora his mother, so they described another Sovereign, Rameses II., as Sesostris. The Greeks, indeed, made a bold, and at the same time an easy, condensation of history by ascribing to this really warlike and brilliant Prince all the achievements in peace or war of many or most of his predecessors.

Rameses, or Sesostris, left behind him some great architectural records. To him are due the magnificent obelisks of Luxor, one of which was transplanted by modern invasion to the Place de la Concorde in Paris. Egyptian obelisks have undergone foreign transplantation in other instances as well as that of the column of Luxor.

One of the obelisks from Heliopolis was moved by the orders of Cleopatra to Alexandria, and in the course of time was conveyed from that spot across the seas and found a resting-place on the Thames Embankment in London. Yet another of these ancient monuments has been borne away from Egyptian soil and transferred to a site in New York. The human mind can hardly conceive a more curious transformation scene than that illustrated by the removal of an Egyptian obelisk from its place in the desert to a home in one of the newest, noisiest, and most crowded cities of the New World.

The Israelites' Task. The captives taken in war by the Egyptian sovereigns were commonly set to work at the erection and ornamentation of these monuments, and the Israelites, a large number of whom had endeavoured to settle comfortably in Lower Egypt, were drawn upon by the ruling power for the supply of workmen, not merely in the building of artistic monuments, but also at the opening of quarries, the making of bricks, and the raising of embankments to secure cities against inundation. Rameses III. was the last of the great line of rulers here described, and his deeds in war and peace are commemorated in a Temple at Thebes.

With the passing away of Rameses came an era of decline in the power of the Egyptian civilisation. One, and probably the main, cause of this decline was that the country had exhausted herself by attempting to spread her dominion too far. The Egyptian rulers had for generations been doing little or nothing to ensure the safety and prosperity of their own people, and were far too much given up to that ambition for the spread of territory which seems to be the weakness of monarchies all over the world.

Egypt might always have been prosperous and secure under the nourishing protection of her great river, and sheltered as she was by the surrounding desert regions from the frequent invasion of foreign intruders. But her kings were too often eager to spread their boundaries at whatever risk, and made it their ambition to obtain full control of the bordering sea, and for that purpose to spread their power over the whole of Northern Asia, and even to establish a settlement on the island of Cyprus. With this view they secured the military services of outlying populations, and thus became surrounded by foreign guards, who in time began to assert their influence as practical rulers of the State.

Ethiopian Invasion. The Ethiopians, or Cushites, took advantage of the opportunity given to them by these local discords to take possession of Upper Egypt. For half a century these Ethiopians ruled over the land which had known the dynasty of the Pharaohs. The Ethiopians were finally expelled from the country, but even the manner of their expulsion tended towards the decline of Egypt's independence, for it was in great measure accomplished by the Persians, who for a time made Egypt their own.

Egypt has never since been a self-ruling country. She was coming to be regarded by the outer world as a mere province of Persia, and was conquered by Alexander the Great, who founded the city of Alexandria, which helped to perpetuate his name. The Romans invaded the country, and ruled it for a time after the death of Cleopatra. Some 400 years after the Christian era Theodosius, the Roman ruler, issued edicts actually suppressing the religion of the Pharaohs.

From that time the story of Egypt becomes mixed up with that of Europe. We shall have to make many references to that story of Egypt during our historical narrative. We may say in advance that the opening up of the country to the commerce of the world by the creation of the Suez Canal was but the realisation of a dream which had been the fond hope of one of the Pharaoh kings, a dream he had attempted to realise many centuries before it was ultimately made a reality by the inspiration and the energy of M. Ferdinand de Lesseps, well within the recollection of living men.

The Assyrian Empire. The history of the Assyrians comes next in chronological order. The two great rivers, the Tigris and the Euphrates, come down from the Armenian mountains, where their sources are close to each other, and they surround in their course, before each pours its waters into the Persian Gulf, a large tract of country, mountainous at the one end and sandy at the other, to which history has given the name of Mesopotamia, meaning a region in the midst of rivers.

The earliest dwellers in Assyria included, in Chaldea, the Cushites, of whom we have heard during the story of Egypt's invasions and dynasties. In the mountainous part were the Turanians, and in another part of this vast territory were the Semitic population, coming of a white-skinned race whose origin cannot be traced back in history, and who have become celebrated throughout the world as the Assyrians, the Hebrews, the Phœnicians, and the Arabs. Assyria owned two of the most famous cities in the world, each of which in turn became the capital of the country, Babylon on the Euphrates and Nineveh on the Tigris. The walls of Babylon are said to have been 50 cubits thick, and to have stood nearly 400 feet in height.

Assyria, like most other regions in those days and in much later days, was made subject to many invasions, which its prosperity and its attractive situation drew upon it. The dynasty of the Pharaohs held the mastery of Assyria for some two centuries at least, but when the decline of Egypt set in the Assyrians released themselves from subjection, and took to invasion and annexation on their own account. They made war against the Hebrews, and their conquest of Hosea, the ruler of Israel, is recorded in the Bible.

THE THREE LAWS OF MOTION

Our Conception of Motion Purely Relative. Newton's Three Laws: the First Law Fully Considered. Mass, Weight, and Speed

By Dr. C. W. SALEEBY

Our Ideas of Motion. Any assertion as to the speed of moving bodies in space, such as we were considering at the end of our last chapter, is purely relative, like every other assertion about motion which it is possible for the human mind to make. We mean that, relatively to the objects of the landscape, the train is moving in a certain direction at a certain rate. Relatively to another sign-post, the train is moving *backwards* at a greater rate, and so forth.

The man on the ship, or in the corridor of the train, is moving backwards relatively to the ship or the train, but forward relatively to the landscape. The solar system is moving towards Vega relatively to certain other stars which the astronomers use as sign-posts, just as the engine-driver might use the telegraph-poles. Concerning the absolute motion of anything no one has any knowledge whatever. Indeed, we must go farther, as Spencer proved, and declare that our very idea of motion is purely relative. When we think of the motion of anything we think merely of its motion relatively to something else. We delude ourselves if we fancy that we can even conceive of absolute motion. Taking any case imaginable, we find that we cannot conceive of the motion of anything save with reference to *something*. Even if we think of no material thing, we are compelled to conceive of motion as relative to points in space. The conception is equally relative whether the points be imagined to be empty or to hold sign-posts.

Kinetics and Statics. Thus, having determined the kinds of motion, and being persuaded that we speak merely of relative motion, we must observe certain of the means by which motion may be measured. Thereafter we may proceed to study the laws of motion. The reader must be reminded of the logic of our order of procedure. We have agreed that the fundamental part of physics is the study of forces. We defined what we meant by a force, and observed that there was involved in it the idea of motion. To that we had to devote some important paragraphs; and now we must proceed to discuss it at length. If the reader desires a special word to indicate the department of dynamics which is concerned with motion, that word is *kinematics* *; but this is not often employed. In its place we use two words—*Kinetics* and *Statics*. The first is the study of cause and effect as applied to motion, it being found that the effect is always proportional to the cause—the motion to the force that produces it; and the second is the study of the balancing or equilibrium of forces, so that the combination of forces, *i.e.* of powers which tend to cause motion, results not in motion, but in rest. Let us now consider the names of the units which are employed in the study of motion. We must have units for time and space—factors plainly involved in all motion—and a unit to express the amount of matter that moves, and other units derived from these.

Standards of Measurement. The unit of time, fortunately in use in all countries, is the *second*.
